ABSTRACT

Background
Scabies is an intensely itchy parasitic infection of the skin. It occurs worldwide, but is particularly problematic in areas of poor sanitation, overcrowding, and social disruption. In recent years, permethrin and ivermectin have become the most relevant treatment options for scabies.

Objectives
To assess the efficacy and safety of topical permethrin and topical or systemic ivermectin for treating scabies in people of all ages.

Search methods
We searched the following databases up to 25 April 2017: the Cochrane Infectious Diseases Group Specialized Register, CENTRAL, MEDLINE, Embase, LILACS, and IndMED. We searched the World Health Organization International Clinical Trials Registry Platform, the ISRCTN registry, CenterWatch Clinical Trials Listing, ClinicalTrials.gov, TrialsCentral, and the UK Department of Health National Research Register for ongoing trials. We also searched multiple sources for grey literature and checked reference lists of included studies for additional trials.

Selection criteria
We included randomized controlled trials that compared permethrin or ivermectin against each other for people with scabies of all ages and either sex.

Data collection and analysis
Two review authors independently screened the identified records, extracted data, and assessed the risk of bias for the included trials.

The primary outcome was complete clearance of scabies. Secondary outcomes were number of participants re-treated, number of participants with at least one adverse event, and number of participants withdrawn from study due to an adverse event.

We summarized dichotomous outcomes using risk ratios (RR) with 95% confidence intervals (CI). If it was not possible to calculate the point estimate, we described the data qualitatively. Where appropriate, we calculated combined effect estimates using a random-effects model and assessed heterogeneity. We calculated numbers needed to treat for an additional beneficial outcome when we found a difference.
We assessed the certainty of the evidence using the GRADE approach. We used the control rate average to provide illustrative clearance rates in the comparison groups.

Main results

Fifteen studies (1896 participants) comparing topical permethrin, systemic ivermectin, or topical ivermectin met the inclusion criteria. Overall, the risk of bias in the included trials was moderate: reporting in many studies was poor. Nearly all studies were conducted in South Asia or North Africa, where the disease is more common, and is associated with poverty.

Efficacy

Oral ivermectin (at a standard dose of 200 μg/kg) may lead to slightly lower rates of complete clearance after one week compared to permethrin 5% cream. According to the average clearance rate of 65% in the trials with permethrin, the illustrative clearance with ivermectin is 43% (RR 0.65, 95% CI 0.54 to 0.78; 613 participants, 6 studies; low-certainty evidence). However, by week two there may be little or no difference (illustrative clearance of permethrin 74% compared to ivermectin 68%; RR 0.91, 95% CI 0.76 to 1.08; 459 participants, 5 studies; low-certainty evidence). Treatments with one to three doses of ivermectin or one to three applications of permethrin may lead to little or no difference in rates of complete clearance after four weeks’ follow-up (illustrative cures with 1 to 3 applications of permethrin 93% and with 1 to 3 doses of ivermectin 86%; RR 0.92, 95% CI 0.82 to 1.03; 581 participants, 5 studies; low-certainty evidence).

After one week of treatment with oral ivermectin at a standard dose of 200 μg/kg or one application of permethrin 5% lotion, there is probably little or no difference in complete clearance rates (illustrative cure rates: permethrin 73%, ivermectin 68%; RR 0.93, 95% CI 0.74 to 1.17; 120 participants, 1 study; moderate-certainty evidence). After two weeks of treatment, one dose of systemic ivermectin compared to one application of permethrin lotion may lead to similar complete clearance rates (extrapolated cure rates: 67% in both groups; RR 1.00, 95% CI 0.78 to 1.29; 120 participants, 1 study; low-certainty evidence).

There is probably little or no difference in rates of complete clearance between systemic ivermectin at standard dose and topical ivermectin 1% lotion four weeks after initiation of treatment (illustrative cure rates: oral ivermectin 97%, ivermectin lotion 96%; RR 0.99, 95% CI 0.95 to 1.03; 272 participants, 2 studies; moderate-certainty evidence). Likewise, after four weeks, ivermectin lotion probably leads to little or no difference in rates of complete clearance when compared to permethrin cream (extrapolated cure rates: permethrin cream 94%, ivermectin lotion 96%; RR 1.02, 95% CI 0.96 to 1.08; 210 participants, 1 study; moderate-certainty evidence), and there is little or no difference among systemic ivermectin in different doses (extrapolated cure rates: 2 doses 90%, 1 dose 87%; RR 0.97, 95% CI 0.83 to 1.14; 80 participants, 1 study; high-certainty evidence).

Safety

Reporting of adverse events in the included studies was suboptimal. No withdrawals due to adverse events occurred in either the systemic ivermectin or the permethrin group (moderate-certainty evidence). Two weeks after treatment initiation, there is probably little or no difference in the proportion of participants treated with systemic ivermectin or permethrin cream who experienced at least one adverse event (55 participants, 1 study; moderate-certainty evidence). After four weeks, ivermectin may lead to a slightly larger proportion of participants with at least one adverse event (extrapolated rates: permethrin 4%, ivermectin 5%; RR 1.30, 95% CI 0.35 to 4.83; 502 participants, 4 studies; low-certainty evidence).

Adverse events in participants treated with topical ivermectin were rare and of mild intensity and comparable to those with systemic ivermectin. For this comparison, it is uncertain whether there is any difference in the number of participants with at least one adverse event (very low-certainty evidence). No withdrawals due to adverse events occurred (62 participants, 1 study; moderate-certainty evidence).

It is uncertain whether topical ivermectin or permethrin differ in the number of participants with at least one adverse event (very low-certainty evidence). We found no studies comparing systemic ivermectin in different doses that assessed safety outcomes.

Authors’ conclusions

We found that for the most part, there was no difference detected in the efficacy of permethrin compared to systemic or topical ivermectin. Overall, few and mild adverse events were reported. Our confidence in the effect estimates was mostly low to moderate. Poor reporting is a major limitation.

2 April 2019

Up to date

All studies incorporated from most recent search

All eligible published studies found in the last search (25 Apr, 2017) were included and one ongoing study was identified (see ‘Characteristics of ongoing studies’ section)
PLAIN LANGUAGE SUMMARY

Ivermectin and permethrin for treating scabies

What is the aim of this review?

The aim of this Cochrane Review was to assess the efficacy and safety of topical permethrin and topical or systemic ivermectin for scabies in people of all ages. We searched for all relevant studies to answer this question and found 15 studies, which we collected and analysed.

Key messages

We found that for the most part, there was no difference detected in the efficacy of permethrin compared to systemic or topical ivermectin. Overall, few and mild adverse events were reported. Our confidence in the effect estimates was mostly low to moderate. Poor reporting of studies was a major limitation.

Additional high-certainty studies are needed to strengthen the confidence in the results and improve the evidence base.

What was studied in the review?

Scabies is an intensely itchy parasitic infection of the skin. It occurs throughout the world, but is particularly problematic in areas of poor sanitation, overcrowding, and social disruption. In recent years, permethrin and ivermectin have become the most relevant treatment options for scabies.

We examined topical permethrin, topical ivermectin, and systemic ivermectin as a treatment for scabies in women and men of all ages. We assessed efficacy as complete clearance of skin lesions at different time points after the start of the treatment. Other outcomes were the number of participants re-treated, the number of participants with at least one adverse event, and the number of participants who stopped participating in the study because they experienced an adverse event.

What are the main results of the review?

We found 15 relevant studies. Nearly all studies were set in South Asia or North Africa. These studies compared systemic ivermectin with topical permethrin, topical ivermectin with topical permethrin, or systemic ivermectin with topical ivermectin to treat people with scabies. All studies were conducted at a single centre with mostly small numbers of participants per study group.

Oral ivermectin may lead to slightly lower rates of complete clearance after one week compared to permethrin cream (low-certainty evidence), but little or no difference in rates of complete clearance by week two (low-certainty evidence). Treatments with one to three doses of ivermectin or one to three applications of permethrin may lead to little or no difference in rates of complete clearance after four weeks (low-certainty evidence).

There is probably little or no difference in complete clearance rates after one week of treatment with oral ivermectin or one application of permethrin lotion (moderate-certainty evidence).

There is probably little or no difference in rates of complete clearance between systemic ivermectin at standard dose and topical ivermectin lotion four weeks after initiation of treatment (moderate-certainty evidence). Likewise, after four weeks, ivermectin lotion probably leads to little or no difference in rates of complete clearance when compared to permethrin cream (moderate-certainty evidence), and there is little or no difference among treatments with systemic ivermectin in different doses (high-certainty evidence).

No participants in the systemic ivermectin or the permethrin group stopped participating in the study because they experienced an adverse event (moderate-certainty evidence). Two weeks after treatment initiation, there is probably little or no difference in the proportion of participants treated with systemic ivermectin or permethrin cream who experienced at least one adverse event (moderate-certainty evidence). After four weeks, ivermectin may lead to a slightly larger proportion of participants with at least one adverse event (low-certainty evidence).

Adverse events in participants treated with topical ivermectin were rare and of mild intensity and comparable to those with systemic ivermectin. For this comparison, it is uncertain whether there is any difference in the number of participants with at least one adverse event (very low-certainty evidence). No participants in the topical or systemic ivermectin group stopped participating in the study because they experienced an adverse event (moderate-certainty evidence).

It is uncertain whether topical ivermectin and permethrin differ in the number of participants with at least one adverse event (very low-certainty evidence). We found no studies comparing one dose versus two doses of systemic ivermectin that assessed safety outcomes.

How up-to-date is this review?

We searched for studies published up to 25 April 2017.
## SUMMARY OF FINDINGS

Summary of findings for the main comparison. Oral ivermectin 200 μg/kg (1 to 3 doses) compared to topical permethrin 5% cream (1 to 3 applications)

| Outcomes                                      | Anticipated absolute effects* (95% CI) | Relative effect (95% CI) | Number of participants (trials) | Certainty of the evidence (GRADE) | Comments                                                                 |
|-----------------------------------------------|----------------------------------------|--------------------------|---------------------------------|----------------------------------|-------------------------------------------------------------------------|
| Complete clearance - week 1                   | 654 per 1000 (353 to 510)              | RR 0.65 (0.54 to 0.78)   | 613 (6 RCTs)                    | ⊕⊕⊝⊝-*                         | In 1 study non-responders were re-treated after 1 week; in 1 study 44.44% of participants (IVER) and 17.86% of participants (PER) were re-treated after 1 week (absolute numbers are unclear). |
| Complete clearance - week 2                   | 744 per 1000 (565 to 804)              | RR 0.91 (0.76 to 1.08)   | 459 (5 RCTs)                    | ⊕⊕⊝⊝                         | In 1 study non-responders were re-treated after 1 week; in 1 study 44.44% of participants (IVER) and 17.86% of participants (PER) were re-treated after 1 week (absolute numbers are unclear). |
| Complete clearance - week 4 - IVER 1 dose versus PER 1 application | 900 per 1000 (774 to 1000) | RR 1.00 (0.86 to 1.16) | 80 (1 RCT)*                     | ⊕⊕⊕⊕*                          | In 3 studies non-responders were re-treated once; in 1 study non-responders were re-treated after 2 and/or 3 weeks (absolute numbers are unclear); in 1 study 12 participants (IVER) and 1 participant (PER) were re-treated after 2 weeks. |
| Complete clearance - week 4 - IVER 1 to 3 doses versus PER 1 to 3 applications | 932 per 1000 (764 to 959) | RR 0.92 (0.82 to 1.03) | 581 (5 RCTs)                    | ⊕⊕⊝⊝                         | In 3 studies non-responders were re-treated once; in 1 study non-responders were re-treated after 2 and/or 3 weeks (absolute numbers are unclear); in 1 study 12 participants (IVER) and 1 participant (PER) were re-treated after 2 weeks. |
| Complete clearance - week 4 - IVER 2 doses versus PER 1 application | 900 per 1000 (747 to 1000) | RR 0.97 (0.83 to 1.14) | 80 (1 RCT)*                     | ⊕⊕⊕⊕*                          | In 3 studies non-responders were re-treated once; in 1 study non-responders were re-treated after 2 and/or 3 weeks (absolute numbers are unclear); in 1 study 12 participants (IVER) and 1 participant (PER) were re-treated after 2 weeks. |
### Summary of findings 2. Oral ivermectin 200 µg/kg (1 to 2 doses) compared to topical permethrin 5% lotion (1 to 5 applications)

| Number of participants with ≥ 1 AE - week 2 | 0 per 1000 (0 to 0) | Not estimable | 55 (1 RCT) | ⊕⊕⊕⊝ MODERATE | 0 events; 44.44% of participants (IVER) and 17.86% of participants (PER) were re-treated after 1 week (absolute numbers are unclear) |

*The risk in the intervention group (and its 95% CI) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI). Abbreviations: AE: adverse event; CI: confidence interval; IVER: ivermectin; PER: permethrin; RCT: randomized controlled trial; RR: risk ratio.*

### GRADE Working Group grades of evidence

**High certainty:** we are very confident that the true effect lies close to that of the estimate of the effect.

**Moderate certainty:** we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

**Low certainty:** our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect.

**Very low certainty:** we have very little confidence in the effect estimate: the true effect is likely to be substantially different from the estimate of effect.

1. Usha 2000; Bachewar 2009; Sharma 2011; Rohatgi 2013; Meenakshi 2014; Wankhade 2016.

2. Downgraded by 1 for serious risk of bias: assessed as moderate.

3. Downgraded by 1 for serious imprecision: CI crosses minimal clinically important difference threshold: statistically significant difference of uncertain clinical importance.

4. Usha 2000; Bachewar 2009; Mushtaq 2010; Sharma 2011; Rohatgi 2013.

5. Downgraded by 1 for serious inconsistency: I² = 61% (P = 0.04).

6. Sharma 2011.

7. Usha 2000; Mushtaq 2010; Chhaiya 2012; Rohatgi 2013; Wankhade 2016.

8. Downgraded by 1 for serious inconsistency: I² = 74% (P = 0.004).

9. Bachewar 2009.

10. Mushtaq 2010; Sharma 2011; Chhaiya 2012; Wankhade 2016.

11. Downgraded by 1 for serious imprecision: CI crosses line of no effect and minimal clinically important difference thresholds: uncertain whether there is any difference.

¹Sharma 2011.
BACKGROUND

This section is based on Strong 2007.

Description of the condition

Scabies is an intensely itchy parasitic infection of the skin that is caused by the Sarcoptes scabiei mite. It occurs worldwide, but is particularly problematic in areas of poor sanitation, overcrowding, and social disruption. The global prevalence of scabies ranges from 0.2% to 71.4%, with large variations in geographical region (Romani 2015a). Highest scabies prevalence is noted in Pacific and Central/South American regions. Children are particularly affected (Romani 2015a), for example, in Germany, infectious disease surveillance data on centralized homes for asylum seekers from 2004 to 2014 revealed 119 outbreaks. Of 615 people diagnosed with an infectious disease, 19% had scabies (Kühne 2016). The Global Burden of Disease Study 2015 concluded that 0.21% of all disability-adjusted life-years were caused by scabies worldwide (Karimkhani 2017).

In resource-rich communities, scabies tends to occur in cyclical epidemics, particularly within institutional living situations such as nursing homes (Scheinfeld 2004), or the army (Mimouni 1998; Mimouni 2003). There is some seasonal variation, with incidence being greater in the winter than in the summer, perhaps related to a tendency of indoor overcrowding, as well as increased mite survival in colder weather (Downs 1999; Hay 2012). In resource-poor communities, the occurrence pattern is quite different, with the disease being endemic in many areas (Chosidow 2000). The prevalence of infections in a community is potentially influenced by changes in social attitudes, population movements, wars, misdiagnosis, inadequate treatment, and changes in the immune status of the population. Scabies infestation represents a considerable burden of ill health in many communities, and although the disease is rarely life-threatening, it causes widespread debilitation and misery (Green 1989).

The S scabiei life cycle begins with the pregnant female laying two to three eggs a day in burrows several millimetres to several centimetres in length in the stratum corneum (outermost layer) of the skin. After about 50 to 72 hours, larvae emerge and make new burrows. They mature, mate, and repeat this 10- to 17-day cycle. Mites usually live for 30 to 60 days (Green 1989). Mites survive for up to three days outside of the human body (CDC 2017a).

Humans are the main reservoir for S scabiei var. hominis (variety of the mite named to reflect the main host species). Scabies is usually spread person to person via direct skin contact, including sexual contact, though transfer via inanimate objects such as clothing or furnishings is also possible (Hay 2004). The mite can burrow beneath the skin within 2.5 minutes, though around 20 minutes is more usual (Alexander 1984). The level of infectiousness of an individual depends in part on the number of mites harboured, which can vary from just a single mite to millions (Chosidow 2000). Humans can also be transiently infected by the genetically distinct animal varieties of S scabiei (for example, var. canis), though cross-infectivity is low (Fain 1978; Walton 2004a).

Clinical infection with the scabies mite causes discomfort and often intense itching of the skin, particularly at night, with irritating papular or vesicular eruptions. While infestation with the scabies mite is not life-threatening, the severe, persistent itch debilitates and depresses people (Green 1989). The classical sites of infestation are between the fingers, the wrists, axillary areas, female breasts (particularly the skin of the nipples), peri-umbilical area, penis, scrotum, and buttocks. Infants are usually affected on the face, scalp, palms, and soles of the feet. Much of the itching associated with scabies is a result of the host immune reaction, and symptoms can take several weeks to appear after initial infestation in a person exposed to scabies for the first time. Symptoms appear after a much shorter interval (one to two days) after re-infestation (Arlian 1989).

A more severe or ‘crusted’ presentation of infestation is associated with extreme incapacity and with disorders of the immune system, such as HIV infection. Clinically this atypical form of scabies presents with a hyperkeratotic dermatosis resembling psoriasis. Lymphadenopathy and eosinophilia can be present, but itching may be unexpectedly mild. People with crusted scabies may harbour millions of mites and are highly infectious (Meinking 1995). The dermatological distribution of mites in such people is often atypical (for example, including the head), and treatment in hospital is advised (Chosidow 2000; Sunderkötter 2016).

Complications are few, although secondary bacterial infection of the skin lesions by group A Streptococcus pyogenes or Staphylococcus aureus, or both, can occur following repeated scratching, particularly in warmer climates (Meinking 1995). Secondary infection with group A Streptococcus can lead to acute glomerulonephritis, outbreaks of which have been associated with scabies (Green 1989; Hoy 2012; Hay 2013).

Diagnosis

Diagnosis on clinical grounds is usually made based on a history of itching (particularly if contacts are also affected) and the finding of lesions at the classical sites. The diagnosis can in most cases be confirmed by microscopically identifying a mite, egg, or mite faeces in a skin scraping, or by extracting a mite from a burrow (Chosidow 2000).

Description of the intervention

Various treatments are available for scabies. These include sulfur compounds, benzyl benzoate, crotamiton, hexachlorocyclohexane, malathion, permethrin, and ivermectin. A number of herbal remedies have also been proposed, including tea tree oil, lippia oil, T ointment, and kakawat poultice (Banez 1999; Oladimeji 2000; Alebiosu 2003; Walton 2004b; Oladimeji 2005).

In recent years, topical permethrin and oral ivermectin have become the most relevant treatment options for scabies (Bunerji 2015; RKI 2016).

Topical permethrin 5% was first licensed in 1989 by the US Food and Drug Administration (Currie 2010). It was approved in Germany in October 2004 (Hamm 2005; InfectoScab 2016). In low- and middle-income countries such as India, where permethrin was approved for treating scabies in 1995 (CDSCO), the treatment is considered expensive, while oral ivermectin seems to be cheaper (Sharma 2011).

In contrast, oral ivermectin was first approved for the treatment of scabies in France in 2001 (Currie 2010); in the past few years it has been approved in Australia and the Netherlands (AusPAR 2013; Merck 2015). Oral ivermectin was approved for the treatment of scabies in Germany in February 2016 (Scabioral 2016), whereas in the USA it is still used off-label (CDC 2017b).
Topical ivermectin has also been investigated for the treatment of scabies in recent years due to the expected therapeutic efficacy. It is not approved for the treatment of scabies, but for treating head lice (0.5% lotion, FDA 2012) and inflammatory lesions of rosacea (1% cream, FDA 2014).

Systemic ivermectin is associated with adverse reactions such as nausea, rash, dizziness, itching, abdominal pain, and fever. Many of these symptoms may be an allergic reaction to the dead parasites rather than to ivermectin itself (Fawcett 2003). An increased risk of death amongst elderly patients in a long-term care facility has been reported with the use of ivermectin (Barkwell 1997). However, the validity of this report has been discussed considerably (Bredal 1997; Coyne 1997; Diazgranados 1997; Reintjes 1997), and its findings could not be confirmed by multiple subsequent studies.

Rare adverse reactions have been reported with the use of permethrin, including neck dystonia (Coleman 2005), pruritus, burning, and stinging (Fawcett 2003).

Prevention

Prevention is based on principles common to most infectious diseases, that is limitation of contact with the mite. An infested person can spread scabies even if no symptoms are present. The probability of transmission is highest with direct and close skin-to-skin contact and happens most frequently between family members. Linen used and worn three days before the start of treatment should be washed thoroughly to avoid spreading scabies (CDC 2017a). Contacts of cases are usually advised to treat themselves at the same time as the case in order to reduce the risk of re-exposure and re-infestation (Sunderkötter 2016).

How the intervention might work

Ivermectin is a broad-spectrum anthelmintic agent, which affects the nervous system of the scabies mite and causes its death (AusPAR 2013). Unlike permethrin, it is not ovicidal. Ivermectin is available as systemic antiscabies drug (200 μg/kg/dose; CDC 2017b). Permethrin is usually available as a 5% cream or 5% lotion. It is a synthetic pyrethroid, which kills the scabies mite and the eggs (CDC 2017b).

In general, permethrin is applied as 5% cream to all areas of the body from head/neck to toe. It is left on overnight or up to 24 hours and then rinsed off. Application is sometimes repeated once, about one to two weeks later. Children aged two months or older can also be treated (Currie 2010; Banerji 2015; CDC 2015; Sunderkötter 2016; CDC 2017b; Salavastru 2017).

Ivermectin is taken orally as a tablet with a dosage of 200 μg/kg body weight, usually once but sometimes a second time after one to two weeks. It has not been tested in pregnant or lactating women and children weighing less than 15 kg. Furthermore, opinions diverge on whether the tablet should be taken with food or on an empty stomach (Currie 2010; Banerji 2015; CDC 2015; Sunderkötter 2016; CDC 2017b; Salavastru 2017).

A follow-up visit to determine whether the patient is cured should ideally occur one month after the initiation of treatment. This time allows for lesions to heal and for any eggs and mites to reach maturity in case the treatment did not work (that is, beyond the longest incubation interval). Patients should be advised that itching may persist for one to two weeks after treatment, even if the mite is successfully eradicated (Buffet 2003). Because of this delay in symptom relief, it may sometimes be difficult to distinguish re-infestation from primary treatment failure.

Why it is important to do this review

Apart from a non-Cochrane systematic review that considered several scabies treatments (Dressler 2016a), there is currently no systematic review focusing on the available evidence comparing ivermectin with permethrin. Using data from randomized controlled trials, this review summarizes and evaluates the existing evidence on the efficacy and safety of permethrin and ivermectin for scabies. We aimed to answer the following questions in relation to safety and efficacy.

- Is oral ivermectin superior to topical permethrin?
- Is oral ivermectin superior to topical ivermectin?
- Is topical ivermectin superior to topical permethrin?
- Is a single dose of oral ivermectin superior to multiple doses of oral ivermectin?

Global epidemics and an increasing number of asylum seekers due to the Middle Eastern population migration highlights the importance of this review to investigate and understand scabies interventions (Kühne 2016; Bloch-Infanger 2017).

A Cochrane Review on ‘Interventions for treating scabies’ was published in 2007 (Strong 2007). This includes an evaluation of crotamiton, lindane, sulfur, and benzyl benzoate; Strong 2007 and earlier published versions are listed in the ‘Other published versions of this review’ section.

OBJECTIVES

To assess the efficacy and safety of topical permethrin and topical or systemic ivermectin for scabies in people of all ages.

METHODS

Criteria for considering studies for this review

Types of studies

We only included randomized controlled trials (RCTs). We considered all study reports irrespective of their publication status and language of publication.

The review protocol was registered with PROSPERO International prospective register of systematic reviews in October 2016 (Rosumek 2016). Very few changes have been made to the proposed methods; see the ‘Differences between protocol and review’ section.

Types of participants

Children or adults of both sexes with a diagnosis of classical scabies, as defined by the study authors.

Types of interventions

Intervention

- Topical permethrin.
- Topical ivermectin.
- Systemic ivermectin.
Control

- One of the above mentioned interventions.

Types of outcome measures

Primary outcomes

- Complete clearance (outcome assessment at 7, 14, and 30 days' post-initiation of treatment).

Secondary outcomes

- Number of people re-treated.
- Number of people with at least one adverse event (outcome assessment at the end of active study period).
- Number of people withdrawn from study due to adverse event (outcome assessment at the end of active study period).

Search methods for identification of studies

We attempted to identify all RCTs regardless of language or publication status (published, unpublished, in press, or in progress).

Electronic searches

Databases

We searched the following databases up to 25 April 2017 using the search terms and strategy described in Appendix 1: the Cochrane Infectious Disease Group Specialized Register; the Cochrane Central Register of Controlled Trials (CENTRAL, published in the Cochrane Library; Issue 4, 2017); MEDLINE (PubMed, from 1946); Embase Ovid (from 1974); LILACS (Latin American and Caribbean Center on Health Sciences Information) (lilacs.bvsalud.org/, from 1982), and IndMED (indmed.nic.in/, from 1985). We also searched EconLit (Economic Literature database, EBSCOHost, from 1993 to 26 July 2016) and ERIC (Education Resources Information Center, EBSCOHost, from 1966 to 26 July 2016).

Grey literature

We searched the following sources for published and unpublished trials up to 26 July 2016:

- British Library Index of Conference Proceedings (explorecatalogue.bl.uk/), search term: "scabies" AND ("trial" OR "study" OR "treatment");
- British Library for Development Studies (blids.ids.ac.uk/), search term: "scabies";
- BRIDGE (www.bridge.ids.ac.uk/), search term: "scabies";
- Social Care Online (www.scie-socialcareonline.org.uk/), search term: "scabies";
- Institute for Development Studies (www.ids.ac.uk/search), search term: "scabies";
- IIED (www.ied.org/), search term: "scabies"; and
- Science.gov (www.science.gov/), search term: "scabies" AND ("trial" OR "study" OR "treatment").

Trials registers

We searched the following sources for registered trials using the term "scabies" up to 25 April 2017:

- World Health Organization International Clinical Trials Registry Platform (WHO ICTRP, apps.who.int/clinicalsearch);
- ISRCTN registry (www.isrctn.com);
- CenterWatch Clinical Trials Listing (www.centerwatch.com);
- US National Institutes of Health Ongoing Trials Register ClinicalTrials.gov (www.clinicaltrials.gov);
- TrialsCentral (www.trialscentral.org); and
- UK Department of Health National Research Register (www.nihr.ac.uk).

Searching other resources

Reference lists

We scanned the reference lists of all included RCTs for further studies.

Correspondence

We attempted to obtain unpublished data via e-mail correspondence with first authors if contact details were available or could be identified.

Data collection and analysis

Several of the following sections may be identical to parts of the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011).

Selection of studies

Two review authors independently screened the titles and abstracts of all studies identified by the search to determine those that were potentially relevant. The full texts of all records assessed as eligible by at least one of the review authors were obtained. We read all available full texts to assess study eligibility according to the inclusion criteria.

We scrutinized the trial reports to ensure that multiple publications from the same trial were identified so that data were only included once (see the Characteristics of included studies table). Reasons for the exclusion of studies during the full-text screening phase are listed in the Characteristics of excluded studies table.

We illustrated the study selection process in a PRISMA flow diagram.

Data extraction and management

Two review authors (SR and CD) independently extracted data from the included trial reports using a standardized data extraction form (Microsoft Word). Items extracted include study characteristics, inclusion and exclusion criteria, baseline data, definition of outcomes, adverse events, and whether participants were re-treated. The form was piloted.

We extracted the number of participants randomized as well as the number of participants analysed for each study arm. For each dichotomous outcomes, we recorded the number of participants experiencing the event in each arm of the trial. If efficacy data were not reported using an intention-to-treat approach, we imputed these data employing a non-responder imputation approach for all intervention and control groups.
Where primary or secondary outcomes were measured at more than one time point, we aimed to extract all relevant data corresponding to 7, 14, and 30 days post-treatment initiation.

For one study, [Usha 2000], we extracted percentages of participants achieving ‘complete clearance of lesions’ (graded as good improvement) from a graph using the Engauge Digitizer software (Engauge Digitizer). We converted the percentages into absolute numbers, as no withdrawals or dropouts were reported.

After comparing the extracted data and resolving any differences through discussion, one review author (SR) entered the data into Review Manager 5 (RevMan 5) [RevMan 2014], and a second review author (CD) checked the data for accuracy.

Assessment of risk of bias in included studies

For each included study, two review authors independently assessed the methodological quality using the Cochrane ‘Risk of bias’ assessment tool [Higgins 2011]. We assessed the following seven domains.

- Random sequence generation.
- Allocation concealment.
- Blinding of participants and personnel.
- Blinding of outcome assessment.
- Completeness of outcome data.
- Selective reporting.
- Other sources of bias.

For each trial, to assess ‘selection bias’ we described the methods used to generate the randomization list and how the allocation was concealed; to assess ‘performance and detection bias’ we stated who was blinded and, if reported, how this was done. In order to assess ‘attrition bias’, we reported the number of participants lost to follow-up and the method study authors used to deal with missing data. If more than 10% of the participants were lost to follow-up in at least one of the study groups, and no imputation method was used to analyse the study outcomes, we evaluated the risk of bias as high. To assess ‘reporting bias’, we described any discrepancies between the methods section (planned measurements) and the results as reported in the included records. For the domain ‘other bias’, we have listed and assessed any other potential sources of bias that may have influenced the studies’ results.

For each of the domains ‘selection bias’, ‘reporting bias’, and ‘other bias’, we made one assessment (‘low risk’, ‘high risk’, or ‘unclear risk’ of bias). For the domains ‘performance bias’, ‘detection bias’, and ‘attrition bias’, we made two assessments: one for all efficacy outcomes and one for all safety outcomes per study. Discrepancies in assessments were resolved by discussion.

Review authors’ judgements about each ‘Risk of bias’ item for each included study are presented in the ‘Risk of bias’ summary figure.

Measures of treatment effect

We presented results as risk ratios (RRs) with corresponding 95% confidence intervals (CIs). If an outcome was positive (for example, clearance), RRs greater than one demonstrate a favourable outcome of the intervention of interest, and these were presented to the right of the line of no effect. In case of negative outcomes (for example, safety), RRs smaller than one demonstrate a favourable outcome of the intervention of interest (represented to the left of the line of no effect). We expressed all statistically significant results as numbers needed to treat for an additional beneficial outcome (NTNB) with 95% CIs [Christensen 2006].

To avoid the problem of multiplicity, we chose only one primary outcome and a limited number of secondary outcomes.

Unit of analysis issues

To avoid unit of analysis errors, we included every study only once in each comparison (for each outcome at each time point). We also used this approach for multi-arm studies given that for each comparison a single effect measure was calculated. This precluded the same group of participants being included more than once in the same meta-analysis.

In one comparison, we combined two arms of a three-arm study for the outcome ‘complete clearance’ [Sharma 2011]. In both arms oral ivermectin 200 μg/kg body weight was administered on day one. After two weeks, participants in one of these arms received an additional dose of oral ivermectin. We considered both arms as treated equally and hence combined the number of events and participants when assessing the outcome after one and two weeks of treatment.

Dealing with missing data

For dichotomous efficacy data, we performed an intention-to-treat analysis. We imputed outcome data for the missing participants using a non-responder imputation approach for the intervention and the control groups, meaning that we assumed treatment failure for all missing participant data (conservative approach, Higgins 2011). Participants were analysed in the group to which they had been randomized. We specified the amount of imputed participant data as footnotes in the forest plots.

Some study authors reported insufficient information on safety outcomes. In such cases we reported data as presented by the study authors.

If there were inconsistencies within a publication regarding the reported data, we asked the author for clarification. We sent two e-mails if contact details were provided in the publication or if we were able to identify them elsewhere.

Assessment of heterogeneity

We assessed heterogeneity by visually inspecting forest plots, calculating an I² statistic, and carrying out a Chi² test for heterogeneity using RevMan 5 [RevMan 2014]. If we detected heterogeneity (that is, I² statistic > 50%), we undertook subgroup or sensitivity analysis, or both, to explore the causes of the heterogeneity [Higgins 2011].

If heterogeneity was low or not detected, we pooled results from trials using a random-effects meta-analysis model, because we anticipated that the different studies would estimate different intervention effects [DerSimonian 1986; Higgins 2011].

Assessment of reporting biases

Had we included 10 or more studies comparing the same intervention, we would have evaluated a funnel plot. However, this was not the case, and we were unable to assess publication bias. We aimed at avoiding the introduction of other types of reporting bias.
at the systematic review level by conducting extensive searches and including all languages.

Data synthesis

We have summarized and presented qualitative information (for example, study design, description of participants, study groups, outcome measurements) in the Characteristics of included studies tables. We calculated RRs and 95% CIs using Review Manager 5 for each of the preselected outcomes and pooled data using a random-effects model if appropriate (RevMan 2014).

Where a meta-analysis could not be performed (for example, due to effects being reported as percentages only), we described the results in the text.

‘Summary of findings’ tables

For each assessed comparison we created a ‘Summary of findings’ table, which included an evaluation of the certainty of evidence according to the GRADE approach described in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011; Schünemann 2013). Using the online tool GRADEpro GDT, we assessed the certainty of the evidence as either high, moderate, low, or very low (GRADEpro GDT). Randomized controlled trials start at high-certainty evidence and are rated down depending on the presence of study limitations (risk of bias), inconsistency, indirectness, imprecision, and publication bias.

Risk of bias

If most of the information was from studies with an overall assessment of moderate or high risk of bias, we downgraded one (serious limitations) or two levels (very serious limitations) (Guyatt 2011a).

Inconsistency

We judged large and unexplained inconsistency based on similarity of point estimates and the extent of overlap of CIs. Depending on the magnitude of inconsistency in study results, we rated down by one or two levels (Guyatt 2011d).

Imprecision

We examined 95% CI for imprecision. If the confidence limit crossed the minimal clinically important difference thresholds, we downgraded one level. Minimal important difference represents the smallest difference between treatment groups for an outcome that clinicians or patients identify as meaningful. By default, these thresholds are 0.75 for appreciable harm and 1.25 for appreciable benefit. If both thresholds were crossed and CIs were wide, we downgraded the certainty by two levels (Guyatt 2011c).

Indirectness

We assessed differences in patient populations, (co-)interventions, and measurement of the outcomes of the pooled studies. Depending on the extent of differences, we downgraded one or two levels (Guyatt 2011e).

Publication bias

Due to the small number of studies pooled, it was inappropriate to evaluate a funnel plot. We rated the likelihood of publication bias based on study size and sponsorship. In case of publication bias, we rated down by one level (Guyatt 2011b).

We justified and documented our assessment in the ‘Summary of findings’ tables (that is, in case of downgrading) using footnotes.

Subgroup analysis and investigation of heterogeneity

Due to the different study designs with respect to drug dosing, we analysed subgroups according to the number of treatment doses - one, one to two, or two doses - for ivermectin 200 µg/kg body weight compared to permethrin 5% cream (for the outcome ‘complete clearance’ assessed after four weeks of treatment).

We investigated statistical heterogeneity by means of sensitivity analysis.

Sensitivity analysis

For two comparisons and outcomes, we conducted sensitivity analyses due to statistical heterogeneity. We could not identify meaningful groups of studies based on ‘Risk of bias’ assessments that would help explain the heterogeneity. We reported effect estimates excluding studies with slightly different treatment schemes or with a contrary result, separately (see Appendix 2).

RESULTS

Description of studies

Results of the search

The electronic searches (see Electronic searches) retrieved 692 references. We found another article coincidentally through a search of the Internet, which we included.

We screened the titles and abstracts of 441 records retrieved through database searches and assessed 19 full-text records for eligibility.

We screened the reference lists of already included trials and found three more potentially relevant studies, two of which met the inclusion criteria.

A total of 15 trials met the inclusion criteria of the review.

Trial register searches identified 17 further studies (including two duplicates); we could include one ongoing trial.

The study selection process can be seen in Figure 1.
Included studies
We included 15 RCTs that investigated 1896 participants treated with ivermectin or permethrin. Details of all included studies are provided in the Characteristics of included studies tables.

We contacted the authors of six studies to obtain missing data or to clarify inconsistent information (Das 2006; Mushtaq 2010; Saqib 2012; Rohatgi 2013; Wankhade 2013; Manjhi 2014); the authors of two studies replied (Saqib 2012; Rohatgi 2013). Details are reported in the respective Characteristics of included studies tables.

Design
All included studies were parallel-group RCTs, and most were conducted as open-label trials. Participants and personnel were blinded to treatment assignment in only one study (Sharma 2011). In a second study, the outcome assessor was blinded (Saqib 2012).

We assumed that all studies recruited participants from one centre, but this was not stated clearly in all study reports.

Seven studies compared two treatment groups. Five of these studies evaluated topical permethrin and systemic ivermectin.
(Usa 2000; Mushtag 2010; Saqib 2012; Rohatgi 2013; Wankhade 2013); one study compared topical ivermectin with systemic ivermectin (Ahmad 2016); and the remaining study compared one versus three treatments of systemic ivermectin (Macotela-Ruiz 1996).

Five studies compared three treatment groups. One study investigated permethrin, systemic ivermectin, and topical ivermectin (Chhaiya 2012); one study compared permethrin with two different regimens of systemic ivermectin (Sharma 2011); and the remaining three studies investigated systemic ivermectin and permethrin as well as another treatment not addressed in this review (benzyl benzoate 25% lotion (Bachewar 2009); gamma benzene hexachloride 1% lotion (Meenakshi 2014); combination of topical permethrin and systemic ivermectin (Wankhade 2016)).

Three studies compared four treatment groups. Abdel-Raheem 2016 investigated topical permethrin and systemic ivermectin (plus two groups treated with sulfur ointment or benzyl benzoate cream not included in this review). Das 2006 also examined the effect of gamma benzene hexachloride 1% and included a placebo group. Manjhi 2014 investigated topical permethrin and systemic ivermectin (plus two groups treated with gamma benzene hexachloride 1% lotion or benzyl benzoate 20% lotion not included in this review).

In two studies, uncured participants were switched to another treatment (Usa 2000; Chhaiya 2012).

The oldest included study was conducted from 1993 to 1995 and was published in 1996 (Macotela-Ruiz 1996), while the three most recent ones were published in 2016 (Abdel-Raheem 2016; Ahmad 2016; Wankhade 2016).

Sample sizes
The sample size varied from 62, in Ahmad 2016, to 315, in Chhaiya 2012. In two studies the numbers of randomized participants per study group were not reported (Mushtag 2010; Wankhade 2013).

Study settings
All studies took place in dermatological outpatient clinics/dermatological departments of medical colleges or hospitals.

Age
Eleven studies included children and adults, with an age range of two to 80 years (Usa 2000; Das 2006; Bachewar 2009; Mushtag 2010; Sharma 2011; Chhaiya 2012; Manjhi 2014; Meenakshi 2014; Abdel-Raheem 2016; Ahmad 2016; Wankhade 2016).

Saqib 2012 included only adults aged 18 to 60. One trial enrolled only children from five to 15 years of age (Rohatgi 2013).

Only three studies reported the mean age at baseline of all included participants. In the study by Abdel-Raheem 2016, the mean age of the 200 participants who completed the study was 25.33 years (standard deviation (SD) 12.84). The mean age at baseline of the 62 randomized participants in the study by Ahmad 2016 was 21.8 years (SD 15). Macotela-Ruiz 1996 did not report the age of participants, but stated a mean age of 12 and 16 years for male and female participants, respectively, in the group treated with one dose of ivermectin 250 μg/kg body weight, and a mean age of 18 and 20 for male and female participants, respectively, in the three-dose group.

Another study by Wankhade 2013, which was available only as an abstract, did not report age.

Sex
All studies recruited both women and men. Eleven studies reported the proportion of female participants, including 639 women (45.22%) and 774 men (Macotela-Ruiz 1996; Usa 2000; Bachewar 2009; Mushtag 2010; Sharma 2011; Chhaiya 2012; Rohatgi 2013; Meenakshi 2014; Abdel-Raheem 2016; Ahmad 2016; Wankhade 2016).

Geographical region
Ten studies were conducted in India (Usa 2000; Das 2006; Bachewar 2009; Sharma 2011; Chhaiya 2012; Rohatgi 2013; Wankhade 2013; Manjhi 2014; Meenakshi 2014; Wankhade 2016), two in Pakistan (Mushtag 2010; Saqib 2012), two in Egypt (Abdel-Raheem 2016; Ahmad 2016), and one in Mexico (Macotela-Ruiz 1996).

Diagnosis of scabies
A detailed description of how scabies was diagnosed in each study is provided as part of the Characteristics of included studies tables. Diagnostic procedures differed greatly. In six studies clinical diagnosis was confirmed by microscopic examination (Das 2006; Chhaiya 2012; Saqib 2012; Rohatgi 2013; Abdel-Raheem 2016; Ahmad 2016). In the study by Wankhade 2016, participants were included based on clinical criteria, even when the microscopic examination was negative. In four studies scabies was diagnosed clinically only (Usa 2000; Bachewar 2009; Sharma 2011; Meenakshi 2014). In the study by Mushtag 2010, only in cases of uncertainty confirmation of the clinical diagnosis was sought by an additional microscopic examination. Three studies did not report diagnostic procedures (Macotela-Ruiz 1996; Wankhade 2013; Manjhi 2014).

Interventions
Treatment duration, frequency, and formulation
The treatment frequency of permethrin ranged from a single application in most included studies (Usa 2000; Das 2006; Bachewar 2009; Mushtag 2010; Sharma 2011; Chhaiya 2012; Saqib 2012; Rohatgi 2013; Wankhade 2013; Manjhi 2014; Wankhade 2016), to a single application daily on five days/nights in a row (Abdel-Raheem 2016). In one study, permethrin was applied on day one and again after one week (Meenakshi 2014).

Most of the included studies administered permethrin as a 5% cream (Usa 2000; Das 2006; Bachewar 2009; Mushtag 2010; Sharma 2011; Chhaiya 2012; Rohatgi 2013; Manjhi 2014; Meenakshi 2014; Wankhade 2016). Two studies investigated permethrin as a lotion (Abdel-Raheem 2016: 5% for adults, 2.5% for children and Saqib 2012: 5%). One study, available as an abstract only, did not report the galenic formulation (Wankhade 2013).

Systemic ivermectin was administered once in 12 studies (Macotela-Ruiz 1996; Usa 2000; Bachewar 2009; Mushtag 2010; Sharma 2011; Chhaiya 2012; Saqib 2012; Rohatgi 2013; Wankhade 2013; Manjhi 2014; Ahmad 2016; Wankhade 2016). In two studies, systemic ivermectin was administered on day one and again one week later (Meenakshi 2014; Abdel-Raheem 2016). In another two studies, two doses of ivermectin - on day one and again after two
weeks - were dispensed (Das 2006; Sharma 2011). In Macotela-Ruiz 1996, ivermectin was given three times: on day one, day seven, and day 10.

Systemic ivermectin was administered orally, in five studies in tablet form (Das 2006; Chhaiya 2012; Rohatgi 2013; Meenakshi 2014; Wankhade 2016). The other 10 studies did not specify whether a tablet or a capsule was used (Macotela-Ruiz 1996; Usha 2000; Das 2006; Mushtaq 2010; Sharma 2011; Saqib 2012; Wankhade 2013; Manjhi 2014; Abdel-Raheem 2016; Ahmad 2016).

Two studies investigated a single application of topical ivermectin (Chhaiya 2012; Ahmad 2016), administered as 1% lotion, in Chhaiya 2012, or as 1% solution, in Ahmad 2016.

Re-treatment

Most studies did not report the absolute numbers of participants needing re-treatment or being re-treated. Only two trials comparing ivermectin with permethrin reported numbers of participants needing a second treatment due to non-response, which was higher in the systemic ivermectin group than in the permethrin group.

We specified any available information on number of participants re-treated as footnotes in the forest plots and in Appendix 3.

Treatment of family members and close contacts

In nine studies, members of the family or close contacts, or both, were treated alongside the study participants.

In four studies, family members, Usha 2000; Rohatgi 2013; Abdel-Raheem 2016, or all contacts of the participants, Saqib 2012, received the same medication as the study participant.

In three studies, contacts were treated irrespective of the participant’s treatment as follows: Sharma 2011 provided all family contacts with topical permethrin 5% cream for single overnight application. Macotela-Ruiz 1996 treated 95 contacts with an oral single dose of 250 µg/kg body weight ivermectin. Bachewar 2009 gave benzyl benzoate 25% lotion to all participants so family members could be treated simultaneously.

Meenakshi 2014 explicitly explained to all participants the importance of treating their family members. Whether medication was dispensed or not was not reported. Ahmad 2016 reported that contacts were treated; the nature and extent of the treatment were not described.

Definition and diagnosis of complete clearance

Three studies provided no definition of ‘clinical cure of scabetic lesions’ (Chhaiya 2012), ‘improvement clinically’ (Das 2006), or ‘cure rate’ (Wankhade 2013). The other studies provided details of the definition and diagnosis of complete clearance, which are given in Appendix 4.

Excluded studies

We excluded five studies after full-text assessment (see Figure 1). Reasons for the exclusion of studies are listed in the Characteristics of excluded studies table.

The objective of Chhaiya 2013 was a cost-effectiveness analysis of topical permethrin versus oral ivermectin. The analysis consists of two study groups of Chhaiya 2012. The study did not report any additional relevant data.

We excluded one study on people with crusted scabies, which was not yet open for participant recruitment (NCT02841215). The aim of this study is to assess the efficacy of ivermectin 400 µg/kg body weight compared to ivermectin 200 µg/kg body weight in severe forms of scabies.

We excluded three studies co-authored by Mohamad Goldust due to suspicion of flawed data (Goldust 2012; Goldust 2013; Ranjkesh 2013). We are aware of several other publications on scabies by Goldust and colleagues. Details are reported elsewhere (Dressler 2016b). The issue was presented and discussed at the annual meeting of the Cochrane Skin Group on 9-10 January 2017 in Berlin: a unanimous decision was made to exclude these studies from the review due to the suspicion of flawed data.

Ongoing studies

One study is still recruiting (NCT02407782), hence results are not yet available.

Risk of bias in included studies

See Figure 2 for the ‘Risk of bias’ evaluations of the included trials. For more details on each assessment, see the ‘Risk of bias table’ for each individual study in the Characteristics of included studies tables.
Figure 2. ‘Risk of bias’ summary: review authors’ judgements about each risk of bias item for each included trial.

| Trial                        | Random sequence generation (selection bias) | Allocation concealment (selection bias) | Blinding of participants and personnel (performance bias): Efficacy | Blinding of participants and personnel (performance bias): Safety | Blinding of outcome assessment (detection bias): Efficacy | Blinding of outcome assessment (detection bias): Safety | Incomplete outcome data (attrition bias): Efficacy | Incomplete outcome data (attrition bias): Safety | Selective reporting (reporting bias) | Other bias |
|------------------------------|---------------------------------------------|-----------------------------------------|------------------------------------------------------------------|---------------------------------------------------------------|-----------------------------------------------------------|-----------------------------------------------------------|---------------------------------------------------------------|---------------------------------------------------------------|---------------------------------------------------------------|-----------|
| Abdel-Raheem 2016           | ●                                           | ●                                       | ●                                                                | ●                                                            | ?                                                         | ?                                                         | ?                                                             | ?                                                             | ?                                                             | ?         |
| Ahmad 2016                  | ●                                           | ●                                       | ●                                                                | ●                                                            | ?                                                         | ?                                                         | ?                                                             | ?                                                             | ?                                                             | ?         |
| Bochewar 2009               | ●                                           | ●                                       | ●                                                                | ●                                                            | ?                                                         | ?                                                         | ?                                                             | ?                                                             | ?                                                             | ?         |
| Chhaiya 2012                | ●                                           | ●                                       | ●                                                                | ●                                                            | ?                                                         | ●                                                         | ?                                                             | ?                                                             | ?                                                             | ?         |
| Das 2006                    | ?                                           | ?                                       | ●                                                                | ●                                                            | ?                                                         | ?                                                         | ?                                                             | ?                                                             | ?                                                             | ?         |

Ivermectin and permethrin for treating scabies (Review)

Allocation

More than half of the included studies used adequate methods to generate random sequence (Bachewar 2009; Mushfaq 2010; Sharma 2011; Chhaiya 2012; Saqib 2012; Meenakshi 2014; Abdel-Raheem 2016; Ahmad 2016). The other seven studies did not report the methods used (Macotela-Ruíz 1996; Usha 2000; Das 2006; Rohatgi 2013; Wankhade 2013; Manjhi 2014; Wankhade 2016).

Four studies reported methods that assured adequate allocation concealment (Bachewar 2009; Sharma 2011; Saqib 2012; Abdel-Raheem 2016). We assessed the remaining 11 studies as at unclear risk of bias (Macotela-Ruíz 1996; Usha 2000; Das 2006; Mushfaq 2010; Chhaiya 2012; Rohatgi 2013; Wankhade 2013; Manjhi 2014; Meenakshi 2014; Ahmad 2016; Wankhade 2016).

Consequently, we judged only four out of 15 studies to be at low risk of selection bias (Bachewar 2009; Sharma 2011; Saqib 2012; Abdel-Raheem 2016).

Blinding

We assessed performance and detection bias for efficacy and safety outcomes separately. There were only minor differences. We assessed nearly all included studies as at high risk of performance and detection bias.

Thirteen studies were at high risk of bias with regard to blinding. Of these, seven studies were not blinded (Macotela-Ruíz 1996; Bachewar 2009; Chhaiya 2012; Rohatgi 2013; Meenakshi 2014; Abdel-Raheem 2016; Wankhade 2016), and six study authors did not report anything about steps taken to ensure blinding of participants or personnel, or both (Usha 2000; Das 2006; Mushfaq 2010; Wankhade 2013; Manjhi 2014; Ahmad 2016). We assessed Sharma 2011, which was was double-blind, as at low risk of performance and detection bias. We assessed Saqib 2012 as at low risk of bias regarding efficacy outcomes as at least the physician was blinded to treatment assignment (single-blind study). We rated this study as at high risk of bias regarding adverse events because participants who are aware of their treatment (no blinding) may pay more attention to adverse events related to the specific mode of application (topical versus oral), which introduces bias.

Incomplete outcome data

We assessed attrition bias for efficacy and safety outcomes separately, which led to different assessments in four studies (Das 2006; Sharma 2011; Chhaiya 2012; Ahmad 2016).

Efficacy outcome

In seven studies none or less than 10% of the randomized participants in at least one of the study groups were lost to follow-up over the duration of the study. We assessed the risk of attrition bias in these studies as low (Usha 2000; Sharma 2011; Saqib 2012; Rohatgi 2013; Abdel-Raheem 2016; Ahmad 2016; Wankhade 2016).

More than 10% of the randomized participants in at least one of the study groups were lost to follow-up in Bachewar 2009, Mushfaq 2010, and Meenakshi 2014. Das 2006 reported results as percentages only; the number of participants evaluated and thus the number of participants eventually lost to follow-up is unclear. Macotela-Ruíz 1996 and Wankhade 2013 reported no numerical outcome data, therefore we assessed the risk of bias as high. A clear explanation of the scales or items used to assess the outcome was missing in Manjhi 2014, which led to an assessment of high risk of bias regarding the reported efficacy outcomes.

We rated the remaining study by Chhaiya 2012 as at unclear risk of bias because the number of participants lost to follow-up was less than 10% (15/315), but the number of participants analysed at week two and three was unclear.

Safety outcome

In six studies, none or less than 10% of the randomized participants in at least one of the study groups were lost to follow-up. We assessed the risk of attrition bias in these studies as being low (Usha 2000; Chhaiya 2012; Saqib 2012; Rohatgi 2013; Abdel-Raheem 2016; Wankhade 2016).

In contrast, more than 10% of the randomized participants in at least one of the study groups were lost to follow-up in Bachewar 2009, Mushfaq 2010, and Meenakshi 2014. No numerical outcome data were reported in Macotela-Ruíz 1996, Wankhade 2013, and Manjhi 2014. We rated these six studies as at high risk of attrition bias. We assessed the remaining three studies as at unclear risk of bias. In Das 2006, the number of participants evaluated for safety was unclear. Sharma 2011 did not report adverse events for each study group separately, and Ahmad 2016 did not report numerical data on participants with adverse events per study group.

Selective reporting

We rated two studies as at high risk of reporting bias. Macotela-Ruíz 1996 and Meenakshi 2014 defined outcomes in the corresponding methods sections but did not report results for these outcomes. We assessed the remaining studies as at unclear risk of reporting bias (Usha 2000; Das 2006; Bachewar 2009; Mushfaq 2010; Sharma 2011; Chhaiya 2012; Saqib 2012; Rohatgi 2013; Wankhade 2013; Manjhi 2014; Abdel-Raheem 2016; Ahmad 2016; Wankhade 2016). None of the included studies provided information about a study protocol.

Other potential sources of bias

We judged three studies as at high risk of other sources of bias. Mushfaq 2010 and Saqib 2012 reported baseline differences between intervention and control group. In addition, there were minor inconsistencies in the publications. The reports by Rohatgi 2013 revealed discrepancies in response data between the abstract and the doctoral thesis the study author provided. We judged all other included studies to be of unclear risk of other sources of bias.

Effects of interventions

See: Summary of findings for the main comparison Oral ivermectin 200 μg/kg (1 to 3 doses) compared to topical permethrin 5% cream (1 to 3 applications); Summary of findings 2 Oral ivermectin 200 μg/kg (1 to 2 doses) compared to topical permethrin 5% lotion (1 to 5 applications); Summary of findings 3 Oral ivermectin 200 μg/kg (1 to 3 doses) compared to topical ivermectin 1% lotion/solution (1 to 3 applications); Summary of findings 4 Topical ivermectin 1% lotion (1 to 3 applications) compared to topical permethrin 5% cream (1 to 3 applications); Summary of findings 5 Oral ivermectin 200 μg/kg (1 dose) compared to oral ivermectin 200 μg/kg (2 doses)

See the 'Summary of findings' tables section.

The included studies investigated the following four comparisons.
口内ivermectin versus topical permethrin.
• Oral ivermectin versus topical ivermectin.
• Topical ivermectin versus topical permethrin.
• Oral ivermectin versus oral ivermectin in different doses.

Data on the following six comparisons are reported here.

• Ivermectin 200 μg/kg body weight (1 to 3 doses) versus permethrin 5% cream (1 to 3 applications).
• Ivermectin 200 μg/kg body weight (1 to 2 doses) versus permethrin 5% lotion (1 to 5 applications).
• Ivermectin 200 μg/kg body weight (1 dose) versus permethrin 5% (of unknown ointment base, 1 application).
• Ivermectin 200 μg/kg body weight (1 to 3 doses) versus ivermectin 1% lotion/solution (1 to 3 applications).
• Ivermectin systemic (1 dose) versus ivermectin systemic (2 to 3 doses).

We have reported comparisons addressing our predefined outcomes in more detail below. If there is no paragraph describing an outcome or a specific time point, it was not reported in any of the included studies.

Figure 3. Forest plot of comparison: 1 Ivermectin 200 μg/kg versus permethrin 5% cream, outcome: 1.1 Complete clearance - week 1.

These results are in line with the results reported by Chhaiya 2012, who stated that after one week of treatment 74.8% of participants treated with permethrin and 30.0% of participants treated with ivermectin achieved complete clearance; absolute numbers were not reported and could not be deducted.

Manjhi 2014 investigated ‘complete improvement’ based on pruritus and lesions separately. A difference for complete improvement based on lesions alone was found in favour of permethrin (RR 0.74, 95% CI 0.56 to 0.99; 120 participants); for complete improvement based on pruritus no difference was found (RR 0.82, 95% CI 0.60 to 1.11; 120 participants).

Two weeks’ follow-up
Six studies reported the outcome ‘complete clearance’ after two weeks of treatment (Usha 2000; Bachewar 2009; Sharma 2011; Chhaiya 2012; Rohatgi 2013). Of these, Chhaiya 2012 reported results as percentages only: 99.0% of participants treated with permethrin and 63.0% of participants treated with ivermectin achieved complete clearance after two weeks. Absolute numbers could not be deducted. The combined effect estimate of the remaining five studies showed no difference between the treatment groups (RR 0.91, 95% CI 0.76 to 1.08; 459 participants; Analysis 1.2, Figure 4). A statistically significant heterogeneity test ($I^2 = 61\%$, $P = 0.04$) led us to further investigate the source of heterogeneity. Risk of bias was low to high and very divergent between studies. We could not identify meaningful groups of
studies based on the ‘Risk of bias’ assessments that would help explain heterogeneity. In the studies by Bachewar 2009 and Rohatgi 2013, uncured participants had been re-treated after one week; absolute numbers were not provided. Visual inspection of the forest plot suggests that the trial by Usha 2000 may be one of the causes of substantial statistical heterogeneity, though we could not identify any clinical or methodological reasons. Omitting either of these studies from the meta-analysis did not substantially change the effect estimate. Sensitivity analyses neither changed the point estimates nor whether the CI crossed the line of no effect (Appendix 2). Hence, we pooled data from all five studies. We rated the certainty of the evidence as low (Summary of findings for the main comparison).

Figure 4. Forest plot of comparison: 1 Ivermectin 200 μg/kg versus permethrin 5% cream, outcome: 1.2 Complete clearance - week 2.

| Study or Subgroup | Ivermectin | Permethrin | Risk Ratio M-H, Random, 95% CI |
|-------------------|------------|------------|-------------------------------|
| Bachewar 2009 (1) | 27         | 34         | 1.00 [0.78, 1.27]             |
| Mushtaq 2010 (2)  | 24         | 44         | 1.15 [0.78, 1.74]             |
| Rohatgi 2013 (3)  | 45         | 50         | 0.98 [0.86, 1.11]             |
| Sharma 2011 (4)   | 57         | 80         | 0.88 [0.71, 1.09]             |
| Usha 2000 (5)     | 14         | 40         | 0.51 [0.32, 0.81]             |
| Total (95% CI)    | 248        | 211        | 0.91 [0.76, 1.08]             |

| Total events      | 167        | 157        |
| Heterogeneity:   $\tau^2 = 0.01, \chi^2 = 13.23, df = 4 (P = 0.04), P = 81\%$ |
| Test for overall effect: $Z = 1.06 (P = 0.28)$ |

Footnotes:
(1) IVER: 44.44% of participants were re-treated after 1 week, 7/34 imputed (NRI); PER: 17.66% of participants were re-treated after 1 week.
(2) IVER: single dose, per-protocol analysis; PER: single application, per-protocol analysis
(3) IVER, PER: participants who showed no signs of cure at 1st follow-up were given same treatment again, 2/50 ITT-NRI for each group
(4) IVER: single dose, supervised, 1/80 imputed (NRI); PER: single application, 2/60 imputed (NRI)
(5) IVER: single dose, supervised, no imputation; PER: single application, no imputation

Four weeks’ follow-up
Seven studies reported ‘complete clearance’ after four weeks (Usha 2000; Das 2006; Mushtaq 2010; Sharma 2011; Chhaiya 2012; Rohatgi 2013; Wankhade 2016).

A study by Sharma 2011 compared one dose of ivermectin with one application of permethrin 5% cream. After four weeks of follow-up no difference was found (RR 1.00, 95% CI 0.86 to 1.16; 80 participants). We rated the certainty of the evidence as high (Analysis 1.3: subgroup 1, Figure 5, and Summary of findings for the main comparison).
Figure 5. Forest plot of comparison: 1 Ivermectin 200 μg/kg (1 to 3 doses) versus permethrin 5% cream (1 to 3 applications), outcome: 1.3 Complete clearance - week 4.

In five studies uncured participants were re-treated after one week, Chhaya 2012; Rohatgi 2013; Wankhade 2016, and/or after two weeks (Usha 2000; Mushtaq 2010; Chhaya 2012; Wankhade 2016). Additionally, Chhaya 2012 planned to switch non-responders to permethrin 5% after three weeks. This could have affected only one participant in the ivermectin group (not clearly stated).

We observed statistically significant heterogeneity between the five trials ($I^2 = 74\%$, $P = 0.004$), but could not identify potential reasons based on either the direction of the effect or due to a different treatment regimen. We also performed subgroup analyses, creating a subgroup excluding the two studies from sensitivity analysis. The test for subgroup differences was non-significant ($I^2 = 6\%$, $P = 0.30$, see Analysis 1.4). Irrespective of the number of pooled studies, the combined estimates showed no differences between the groups (RR 0.92, 95% CI 0.82 to 1.03; 581 participants, 5 trials; Analysis 1.3: subgroup 2, Figure 5, Appendix 2 for sensitivity analysis). We rated the certainty of the evidence as low (Summary of findings for the main comparison).

In the trial by Das 2006, 90.0% of participants treated with permethrin and 96.0% of participants treated with ivermectin achieved ‘improvement clinically’ after four weeks (no further information provided).

Number of participants re-treated

None of the included studies had a predefined outcome measure assessing the ‘number of participants re-treated’. Hence, reporting differed greatly. Most studies did not report absolute numbers or proportions of participants having been re-treated. In Appendix 3, we have provided an overview of when treatment was repeated. Only two studies did not repeat their intervention - neither as part of the treatment schedule nor in response to uncured participants.

Number of participants with at least one adverse event

The reporting of adverse events was poor.
Two weeks' follow-up

In the study by Bachewar 2009, none of the 55 participants experienced any adverse events. An effect estimate is not calculable; we rated the certainty of the evidence as moderate (Analysis 1.5 and Summary of findings for the main comparison).

Four weeks' follow-up

Four studies including 502 participants reported data for participants experiencing at least one adverse event after four weeks (Mushfaq 2010; Sharma 2011; Chhaja 2012; Wankhade 2016). We found low-certainty evidence that ivermectin may lead to a slightly larger proportion of participants with at least one adverse event (RR 1.30, 95% CI 0.35 to 4.83; moderate heterogeneity: I² = 48%; P = 0.12; Analysis 1.6, Figure 6, Summary of findings for the main comparison).

Figure 6. Forest plot of comparison: 1 Ivermectin 200 μg/kg versus permethrin 5% cream, outcome: 1.5 Number of participants with ≥ 1 adverse event - week 4.

| Study or Subgroup | Ivermectin Events | Permethrin Events | Total | Weight | Risk Ratio | Risk Ratio |
|------------------|-------------------|-------------------|-------|--------|------------|------------|
|                   |                   |                   |       |        |            |            |
| Chhaja 2012 (1)   | 2                 | 100               | 1     | 69     | 1.98 (0.18, 21.40) |            |
| Mushtaq 2010 (2)  | 8                 | 44                | 1     | 42     | 23.3%      | 7.54 (1.08, 50.46) |
| Sharma 2011 (3)   | 6                 | 79                | 5     | 30     | 38.0%      | 0.50 (0.19, 1.77)  |
| Wankhade 2016 (4) | 1                 | 50                | 2     | 19.4%  | 50.56 (0.35, 5.34) |
| Total (95% CI)    | 273               | 229               | 100.6%|        | 1.30 (0.35, 4.83) |
| Total events      | 17                |                   | 9     |        |            |            |

Heterogeneity: Tau² = 0.86, Chi² = 5.79, df = 3 (P = 0.12); P = 48%

Test for overall effect: Z = 0.30 (P = 0.70)

Das 2006 and Rohatgi 2013 reported zero events per group, however the number of participants assessed at week four is unclear.

In the trial by Usha 2000, participants were evaluated after eight weeks. In the ivermectin group, three out of 40 participants experienced at least one adverse event, while none of the 45 analysed participants in the permethrin group experienced an event.

Number of participants withdrawn from study due to adverse event

Four weeks' follow-up

In three studies with 305 randomized participants (Usha 2000; Manjhi 2014; Wankhade 2016), no withdrawals due to adverse events occurred (Analysis 1.7). We rated the certainty of the evidence as moderate (Summary of findings for the main comparison).

Ivermectin 200 μg/kg body weight (1 to 2 doses) versus permethrin 5% lotion (1 or 5 applications) (227 participants, 2 trials)

Two studies compared oral ivermectin 200 μg/kg body weight with permethrin 5% lotion (Saqib 2012; Abdel-Raheem 2016). In the study by Abdel-Raheem 2016, children randomized to the permethrin group below the age of 10 were treated with permethrin 2.5% lotion.

Complete clearance

One and two weeks' follow-up

In Saqib 2012, participants were treated with either a single dose of ivermectin or a single application of permethrin 5% lotion. Complete clearance was defined as no itching, cutaneous lesions/burrows, and negative microscopy. There was no difference between study groups (week one: RR 0.93, 95% CI 0.74 to 1.17; Analysis 2.1: subgroup 1; week two: RR 1.00, 95% CI 0.78 to 1.29; Analysis 2.2: subgroup 1; 120 participants each). We rated the certainty of the evidence as moderate and low, respectively (Summary of findings 2).

In the study by Abdel-Raheem 2016, 107 participants were treated either with a single dose of ivermectin or with permethrin 5% lotion on five consecutive nights. Complete clearance was defined as negative parasitological examination of the participant with complete absence of new lesions. After one week, permethrin may have lead to slightly more participants with complete clearance (RR 0.70, 95% CI 0.47 to 1.03; Analysis 2.1: subgroup 2). After two weeks, no difference was found (RR 0.97, 95% CI 0.81 to 1.17; Analysis 2.2: subgroup 2). We rated the certainty of the evidence as low and moderate, respectively (Summary of findings 2).

Number of participants re-treated

The two studies comparing ivermectin 200 μg/kg with permethrin 5% lotion had different treatment schedules, as shown in Appendix 3.
Number of participants with at least one adverse event

**Two weeks' follow-up**

Abdel-Rahem 2016 found no difference between groups in number of participants with at least one adverse event (RR 5.00, 95% CI 0.25 to 101.58; 100 participants; Analysis 3.3). We rated the certainty of the evidence as very low (Summary of findings 2).

**Number of participants withdrawn from study due to adverse event**

**Two weeks' follow-up**

Saqib 2012 reported that no participants withdrew from the study due to adverse events in either group (120 participants; Analysis 2.4). We rated the certainty of the evidence as moderate (Summary of findings 2).

**Ivermectin 200 μg/kg body weight (1 dose) versus permethrin 5% (1 application) (100 participants, 1 trial)**

We identified only one study, Wankhade 2013, whose data were published as an abstract only.

**Complete clearance**

Wankhade 2013 investigated ivermectin 200 μg/kg body weight and permethrin 5% of unknown ointment base. Participants were evaluated one and two weeks post-treatment initiation. The authors state that “Permethrin had significantly better cure rate than ivermectin” (Wankhade 2013). The number of randomized participants per group, the definition of ‘cure’, and the time point of evaluation were not reported.

**Number of participants re-treated**

Wankhade 2013 stated that participants with no sign of cure received the same treatments again after one week (Appendix 3).

**Oral ivermectin versus topical ivermectin**

**Ivermectin 200 μg/kg body weight (1 to 3 doses) versus ivermectin 1% lotion/solution (1 to 3 applications) (272 participants, 2 trials)**

Two studies compared ivermectin oral with ivermectin 1% lotion, Chhaiya 2012, or 1% solution, Ahmad 2016.

**Complete clearance**

**One-week follow-up**

In Ahmad 2016, there was no difference between study groups after one week of follow-up (RR 0.84, 95% CI 0.65 to 1.08; 62 participants; Analysis 3.1). We rated the certainty of evidence as low (Summary of findings 3).

In Chhaiya 2012, 30.0% of participants treated with ivermectin 200 μg/kg body weight and 63.3% of participants treated with ivermectin 1% lotion achieved 'complete clearance' after one week. Reported data were insufficient to calculate an effect estimate.

**Two weeks' follow-up**

In Ahmad 2016, there was no difference between study groups after two weeks of follow-up (RR 1.00, 95% CI 0.94 to 1.06; 62 participants; Analysis 3.2). We rated the certainty of evidence as moderate (Summary of findings 3).

In Chhaiya 2012, 63.0% of participants treated with ivermectin 200 μg/kg body weight achieved 'complete clearance', whereas 100.0% of participants treated with ivermectin 1% lotion were cleared after two weeks of follow-up. Absolute numbers of participants were not reported (Chhaiya 2012).

**Four weeks' follow-up**

Pooled data from Chhaiya 2012 and Ahmad 2016 revealed no difference between study groups for 'complete clearance' after four weeks of follow-up (RR 0.99, 95% CI 0.95 to 1.03; 272 participants; Analysis 3.3). We rated the certainty of evidence as moderate (Summary of findings 3).

**Number of participants with at least one adverse event**

**Four weeks' follow-up**

Ahmad 2016 re-treated non-responders after one week. Four out of 32 participants in the topical ivermectin group and eight out of 30 participants in the systemic ivermectin group were re-treated. Chhaiya 2012 re-treated those participants who were not cured at week one and week two. Non-responders at week three switched to permethrin. Absolute numbers were not reported (Appendix 3).

**Number of participants withdrawn from study due to adverse event**

**Four weeks' follow-up**

We found no difference between groups for the number of participants with at least one adverse event within four weeks of follow-up (RR 5.05, 95% CI 0.25 to 103.87; 201 participants; Analysis 3.4). We rated the certainty of evidence as very low (Summary of findings 3).

**Number of participants re-treated**

Ahmad 2016 re-treated those participants who were not cured after week one and week two. Non-responders at week three switched to permethrin. Absolute numbers were not reported (Appendix 3).

**Topical ivermectin versus topical permethrin**

**Ivermectin 1% lotion (1 to 3 applications) versus permethrin 5% cream (1 to 3 applications) (210 participants, 1 trial)**

Complete clearance

**One-week follow-up**

In Chhaiya 2012, 69.3% of participants treated with ivermectin 1% lotion achieved 'complete clearance', whereas 74.8% of participants treated with permethrin 5% cream achieved 'complete clearance' after one week. Reported data were insufficient to calculate an effect estimate.

**Two weeks' follow-up**

After two weeks of follow-up, 100.0% of the participants treated with ivermectin 1% lotion achieved 'complete clearance' and 99.0% of the participants treated with permethrin 5% cream were cleared. Absolute numbers of participants were not reported.

**Four weeks' follow-up**

Data reported by Chhaiya 2012 showed no difference between the study groups after four weeks of follow-up for complete clearance (RR 1.02, 95% CI 0.96 to 1.08; 210 participants; Analysis 4.1). We rated the certainty of the evidence as moderate (Summary of findings 4).

cure rates based on anticipated absolute effects: oral ivermectin 97%, ivermectin lotion 96%; RR 0.99, 95% CI 0.95 to 1.03; 272 participants, 2 studies; moderate-certainty evidence; up to two re-treatments of non-responders, numbers unclear; Chhiaia 2012 and Ahmad 2016). The dose comparison study showed that one dose of systemic ivermectin led to little or no difference in rates of complete clearance compared to two doses of systemic ivermectin (extrapolated cure rates based on anticipated absolute effects: 2 doses 90%, 1 dose 87%; RR 0.97, 95% CI 0.83 to 1.14; 80 participants, 1 study; high-certainty evidence). This finding weakened our assumptions as described above. While this study had one of the smallest sample sizes, the methodological conduct and reporting appeared best, giving it more weight.

We did not identify any differences in efficacy between permethrin and ivermectin other than after one week of treatment. Our findings do not allow for a conclusion about the onset of action in topical treatments compared to systemic treatments, as this was not directly assessed.

Safety

Generally, systemic and topical drugs can lead to different types of events, endangering blinding. Only two of the studies included in this review were blinded. While the reporting of adverse events in the included studies was suboptimal, it appears that very few adverse events occurred. Two weeks after treatment initiation, there is probably little or no difference in the proportion of participants treated with systemic ivermectin or permethrin cream who experienced at least one adverse event (35 participants, 1 study; moderate-certainty evidence). After four weeks, ivermectin may lead to a slightly larger proportion of participants with at least one adverse event (extrapolated rates: permethrin 4%, ivermectin 5%; RR 1.30, 95% CI 0.35 to 4.83; 502 participants, 4 studies; low-certainty evidence). In scabies treatment, medications are sometimes given more than once. However, even the studies with repeated applications did not report more adverse events. To add, no withdrawals due to adverse events occurred in either the systemic ivermectin or the permethrin group (moderate-certainty evidence). In most studies in which participants were treated only once, a possible explanation for zero withdrawals could be that participants who experienced adverse events after their first (and only) treatment remained in study because they had already had their treatment.

The studies analysed for this review reported severe itching, secondary bacterial infections, headache, and pruritus in people treated with systemic ivermectin (Mushtaq 2010; Sharma 2011).

Regarding permethrin, the analysed studies in this review rarely stated the frequency of adverse events and did not designate their types. Only erythema, burning, and pruritus were reported during permethrin treatment (Mushtaq 2010; Sharma 2011).

Two analysed studies evaluating systemic versus topical ivermectin reported that adverse events were rare and of mild intensity and comparable in both study groups (Chhiaia 2012; Ahmad 2016). It is uncertain whether there was any difference in the proportion of participants with at least one adverse event (very low-certainty evidence). No withdrawals due to adverse events occurred, which supports these findings (62 participants, 1 study; moderate-certainty evidence).

Furthermore, it is uncertain whether topical ivermectin or permethrin differ in the number of participants with at least one adverse event (very low-certainty evidence). We found no studies comparing systemic ivermectin in different doses that assessed our predefined safety outcomes.

Overall completeness and applicability of evidence

Applicability to Western countries and external validity - apart from the obvious differences between RCT conditions and real-world conditions - is limited due to studies being conducted in regions with a high prevalence of scabies. Most included trials were conducted in lower-middle-income countries (India, Pakistan, and Egypt). Only one study was undertaken in Mexico in the beginning of the 1990s (middle-income country). All studies were conducted in resource-poor countries.

We identified only single-centre studies that included predominately small numbers of participants per study group. The included studies were inconsistent in their descriptions, definitions, and assessments of cure as well as in the frequencies of treatment application. Pooling data or comparing data across participant groups was therefore difficult or inappropriate.

Although permethrin is an ovicidal medication, in some of the included studies it was applied twice. Conversely, in some studies evaluating ivermectin, a non-ovicidal medication, the drug was administered only once. None of these studies explained the scientific rationale behind these a priori defined dosages, although permethrin is often administered twice due to compliance and re-infestation issues (see How the intervention might work).

Quality of the evidence

We assessed the certainty of the evidence according to the GRADE approach and presented it in five ‘Summary of findings’ tables (Summary of findings for the main comparison; Summary of findings 2; Summary of findings 3; Summary of findings 4; Summary of findings 5).

The main reasons for downgrading the certainty of the evidence were the quality of the trials and imprecision in the results. In general, the methodological quality of the trials included in this review was moderate. We assessed most of the studies as having a high risk of performance and detection bias. We rated attrition bias as high in nearly half of the included studies. We downgraded certainty for imprecision, mainly because minimal clinically important difference thresholds were crossed by the CIs or the CIs were wide.

Substantial heterogeneity between trials became apparent in two meta-analyses (Analysis 1.2 and Analysis 1.3). This could be explained by variations in the numbers of re-treated participants, which were not stated in most studies. However, the sensitivity analyses (Appendix 2) did not help to further explain this, and it restricts our confidence in the results.

Potential biases in the review process

While we considered publication bias to be undetected, we cannot rule it out. Nearly all included studies were conducted in resource-poor nations. It is unknown if studies were conducted but not published or not identified through our comprehensive searches. One-fifth of the included studies were not identified
Further limitations apply with regard to the age of the patients and in case of pregnancy and breastfeeding. Systemic ivermectin is not indicated during pregnancy or for children weighing less than 15 kg.

The need for a single versus a repeated application cannot be properly answered based on the identified trial results. For most patients, a single treatment is likely sufficient. The treating physician may take into account the extent of the disease, the number of contact persons affected, the likeliness of correct application, the immune status, and the clinical response during follow-up as an indicator for the need of a second application.

**Implications for research**

Due to suboptimal study conduct, design, or reporting and, for example, the small sample sizes, the certainty of the level of evidence is restricted, which limits our confidence in the effect estimates. Randomized controlled trials of good methodological quality complying with current reporting standards (for example, CONSORT) are necessary to reduce risk of bias and improve the evidence base.

The question of repeated treatment, that is when and how often, cannot be answered conclusively. Further studies with clear and strict treatment regimens are needed.

Adverse events were rare and poorly reported in the included studies. Studies with a larger sample size and better documentation and classification of adverse events could overcome this issue.

The proportion of participants withdrawn due to non-response or adverse events is poorly reported. It is unlikely that new studies from middle-income countries investigating systemic ivermectin versus topical permethrin will change the results (Mounsey 2009).

Discussions on resistance to scabious treatments have emerged, however such cases have been regionally limited, and the overall evidence is scarce. Studies focusing on a possible development of resistance may become necessary in the future.

Public health questions like mass drug interventions for prevention and treatment of scabies were not addressed in this review but could be part of further research and other reviews (Romani 2015b).

**Acknowledgements**

We thank Mark Strong and Paul Johnstone, authors of the Cochrane Review ‘Interventions for treating scabies’ (Strong 2007), which served as a basis for this review. We are heavily indebted to both of them for passing the topic on to us and for preparing the ‘Background’ section. We are also grateful to Anne-Marie Stephani and Paul Garner of the editorial office of the Cochrane Infectious Diseases Group (CIDG) for their administrative support. We thank Vittoria Lutje for preparing and running the searches in online databases and trial registries.

The CIDG editorial base is funded by the UK Department for International Development (DFID) for the benefit of low- and middle-income countries (Grant: 5242).

We are also grateful to Ricardo Niklas Werner for the translation, data extraction, and evaluation of the study published in Spanish.
Ivermectin and permethrin for treating scabies (Review)

Ivermectin and permethrin for treating scabies (Review)

Abdel-Raheem 2016

Methods

Single-centre, parallel-group randomized trial

Duration: 7 months, from November 2012 to May 2013

Participants

Inclusion criteria

- Aged 5 to 50 years
- Clinical presentation of scabies: people experiencing itching and had characteristic lesions (that is, burrows, vesicles, papules, nodules or pustules) on anatomical sites of predilection for scabies (that is, burrows, vesicles, papules, nodules or pustules) on anatomical sites of predilection for scabies

is, the interdigital folds of the hands, the elbows, the wrists, the buttocks, the axillary folds, the nipple areolas in women and the male external genitalia); detailed physical and dermatological examination was done including description of the lesions and their distribution on the body and assessment of the degree of pruritus

- Identification of a mite: parasitological examination of lesions was performed by low-power microscopy; at least 4 to 6 scrapings per participant from separate locations were obtained, placed in a drop of 10% potassium hydroxide solution on a glass slide, and examined for the presence of living Sarcoptes scabiei (that is, adult forms), eggs, or faecal pellets

**Exclusion criteria**

- Pregnant or lactating women
- Body weight less than 15 kg
- People with a systemic condition such as abnormal liver and kidney functions, known thyroid disease, cardiac disorders, nervous system disorders and psychiatric illnesses
- People with history of diabetes mellitus, hypertension, or chronic infectious diseases
- People having any other associated skin disease that could alter the picture of scabies
- Immunocompromised individuals
- Atypical presentations like crusted scabies
- People with any antiscabietic treatment in the preceding month

**Baseline characteristics**

(n = 50 completers in each group)

- Age (mean ± SD): group A: 27.84 ± 9.46, B: 25.28 ± 13.73, C: 22.52 ± 12.77, D: 28.40 ± 13.42
- Males/females: group A: 26/24, B: 14/36, C: 24/26, D: 20/30

**Interventions**

A: Oral ivermectin 200 μg/kg body weight at day 1 and 7, taken with meals; tablets were taken in the presence of the physician (n = 53 participants)

B: Permethrin 2.5% (for children below 10 years) or 5% (for adults) lotion applied by participant and left overnight to the whole body below neck for 5 consecutive nights (n = 54 participants)

Not included in this review:

C: Benzyl benzoate 20% cream applied by participant and left overnight to the whole body below neck for 5 consecutive nights (n = 55 participants)

D: Sulfur ointment, 5% (for children below 10 years) or 10% (for adults) applied by participant and left overnight to the whole body below neck for 5 consecutive nights (n = 54 participants)

- Participants were first treated from secondary bacterial infection, if present, with azithromycin once daily for 3 days.
- Cured participants were prescribed antihistaminic for symptomatic treatment of remaining pruritus and/or nodules, and the uncured participants were prescribed repeated intervention along with antihistaminic.
- Members of the same family not enrolled in the study were given the same drugs according to their age or any other suitable regimen.

**Outcomes**

- Complete cure (negative parasitological examination of the participant with complete absence of new lesions; residual and all new lesions were scraped for detection of mites; if only 1 mite was detected, this was considered as treatment failure; week 1 and 2)
- Number of participants re-treated (week 1)
- Number of participant with ≥ 1 adverse event

### Ahmad 2016

#### Methods
Single-centre, randomized trial
Duration: not stated

#### Participants

**Inclusion criteria**
- Age ≥ 5 years and > 15 kg body weight
Clinically and laboratory diagnosed scabies:
- Clinical diagnosis was based on the presence of ≥ 3 out of 4 criteria: nocturnal pruritus, family history of similar illness, clinical demonstration of burrows, scabies lesions at typical sites
- Laboratory diagnosis: demonstration of mites and/or mite products (eggs, larva, or faecal pellets) in scrapings from skin lesions (burrows or scabetic papules from classical sites) using light microscopy after incubation in 15% potassium hydroxide

Exclusion criteria
- Pregnant and lactating women
- People with crusted (Norwegian) scabies
- People with history of epileptic fits, immunodeficiency, secondary cutaneous infection or eczematization, and coexisting skin disease that could interfere with treatment evaluation
- People with history of recent scabetic treatment
- Known hypersensitivity to ivermectin

Baseline characteristics
- Age (mean ± SD): 21.8 ± 15
- Males/females: 26/36

Interventions
- A: Ivermectin 1% solution applied once to entire body below neck at night (n = 32 participants)
- B: Oral ivermectin 200 μg/kg body weight after food on day 1 (n = 30 participants)
- Treatment was repeated after 1 week only in participants with persistent symptoms.
- Treatment of contacts and proper hygienic measures were emphasized.

Outcomes
- Cure ("effective" = marked to excellent improvement in pruritus (score 0) and no lesions, absence of mites and their products on microscopy; score: 0 = no pruritus, no skin lesions; 1 = mild pruritus, ≤ 10 lesions; 2 = moderate pruritus, 11 to 49 lesions; 3 = marked pruritus, ≥ 50 lesions; week 1, 2, and 4)
- Number of participants withdrawn from study due to adverse event

Funding source
- Not stated

Declarations of interest
- Not stated

Notes
- Location: Minia, Egypt

Risk of bias

| Bias                                           | Authors' judgement | Support for judgement                                                                 |
|------------------------------------------------|--------------------|---------------------------------------------------------------------------------------|
| Random sequence generation (selection bias)    | Low risk           | Quote (page 59): “adaptive biased-coin randomization”                                 |
| Allocation concealment (selection bias)        | Unclear risk       | Insufficient information                                                              |
| Blinding of participants and personnel (performance bias) | High risk          | No information                                                                       |
| Efficacy                                       |                    |                                                                                       |
| Safety                                         | High risk          | No information                                                                       |

Ahmad 2016 (Continued)
### Methods

**Participants**

**Inclusion criteria**

- Above 12 years of age
- Newly diagnosed with scabies (diagnosis was based on clinical symptoms and clinical history)
- Person had to satisfy ≥ 3 of following criteria: history of contact with a person with scabies, complaint of nocturnal itching, history of involvement of family members, presence of classical burrows on clinical examination, presence of typical scabetic lesions like papules, nodules, or vesicles

**Exclusion criteria**

- Pregnant or lactating women; women of childbearing age or planning for conception in near future
- Abnormal liver and kidney functions, known thyroid disease, cardiac disorders, nervous system disorders, and psychiatric illnesses; people with history of diabetes mellitus, hypertension, or chronic infectious diseases
- Any concurrent medication for other illness, consuming tobacco in any form, alcohol, or any substance of abuse
- Any other associated skin disease that could alter the picture of scabies
- Known/suspected immunocompromised individuals
- Scabies with atypical presentations
- Intake of any antiscabetic treatment in the preceding week
- Noncompliant participants

**Baseline characteristics**

- Males/females: group A: 22/12, B: 18/16, C: 23/12

**Interventions**

- A: Permethrin 5% cream applied once to whole body below neck, left overnight (n = 34 participants)
- B: Oral ivermectin 200 μg/kg body weight as single dose, given as supervised medication along with printed handouts of “do’s” in the local vernacular language (n = 34 participants)
Bachewar 2009 (Continued)

- Same treatment was repeated if there were no signs of cure after 1 week.
- All participants were issued 25% benzyl benzoate lotion for topical application for family members and close contacts.

Not included in this review:

C: Benzyl benzoate 25% lotion applied to whole body below neck, left overnight, on 2 consecutive nights (n = 35 participants)

| Outcomes |  |
| --- | --- |
| • Cure (no new lesions (papules, vesicles, and classical burrows), examined by dermatologist and principal investigator; week 1 and 2) |  |
| • Number of participants with ≥ 1 adverse event |  |

| Funding source |  |

| --- | --- | --- |
| Random sequence generation (selection bias) | Low risk | Quote: “random allocation number generated through computer” |
| Allocation concealment (selection bias) | Low risk | Quote: “number [...] provided with any one of the chosen three therapeutic interventions” |
| Blinding of participants and personnel (performance bias) | High risk | Quote: “our study was biased due to nonblinding” |
| Blinding of outcome assessment (detection bias) | High risk | Quote: “our study was biased due to nonblinding” |
| Incomplete outcome data (attrition bias) | High risk | 23/103 participants lost to follow-up (permethrin group: 6; oral ivermectin group: 7; benzyl benzoate group: 10)
No intention-to-treat analysis performed. Quote: Table 1 and 2 |
Bachewar 2009 (Continued)

| Selective reporting (reporting bias) | Unclear risk | Insufficient information |
|-------------------------------------|--------------|--------------------------|
| Other bias                          | Unclear risk | -                        |

Chhaiya 2012

Methods

Single-centre, parallel-group randomized trial

Duration: 1 year and 8 months, from June 2007 to January 2009

Participants

Inclusion criteria

- Aged 5 to 80 years
- Clinically diagnosed scabies:
  - Microscopically diagnosed scabies (demonstration of egg, larvae, mite, or faecal material)
  - In case of negative microscopic examination, person had to satisfy ≥ 3 of following criteria: presence of typical scabietic lesions (papules, nodules, or vesicles at classical sites), presence of classical burrows on clinical examination, nocturnal pruritus, history of involvement of family member or similar symptoms in contacts

Exclusion criteria

- Pregnant women and lactating mothers
- Person treated with any topical scabicidal therapy in the month before entry
- People taking any topical or systemic antibiotic therapy in the week before entry into the study
- Immunologically compromised patients
- Having scabies with atypical presentation like crusted scabies or scabies incognito
- People with secondary bacterial infection
- History of allergy to any of the study drugs
- Blood pressure < 100/60 mmHg

Baseline characteristics

- Age (mean ± SD): group A: 23.40 ± 13.55, B: 21.97 ± 13.26, C: 22.52 ± 12.69
- Males/females: group A: 58/47, B: 58/47, C: 59/46

Interventions

A: Permethrin 5% cream applied once to whole body covering neck to toe, left for ≥ 8 hours, along with printed information sheet in the local vernacular language (n = 105 participants)

B: Oral ivermectin 200 µg/kg body weight as single dose, self administered along with printed information sheet in the local vernacular language (n = 105 participants)

C: Ivermectin 1% lotion, left for ≥ 8 hours, along with printed information sheet in the local vernacular language, containing details regarding application of drug and other instructions (n = 105 participants)

- Participants who were not cured were prescribed repeat intervention along with antihistaminic at each follow-up.
- Participants who were not cured at the end of 3rd week were switched over to standard treatment with 5% permethrin.
- All participants received oral hydroxyzine 10 mg or 25 mg twice daily for symptomatic treatment of pruritus.

Outcomes

- Clinical cure of scabietic lesions (no definition; week 1, 2, 3, and 4)
- Number of participants re-treated (week 1, 2, 3, and 4)
- Number of participants with ≥ 1 adverse event

### Methods

**Das 2006**

**Ivermectin and permethrin for treating scabies (Review)**

Copyright © 2018 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.
### Participants

**Inclusion criteria**
- At least 2 years of age
- Scabies (microscopic and clinical confirmation)

**Exclusion criteria**
- Pregnant women

**Baseline characteristics**
- Age: 3 to 71 (age 0 to 5: 9%, age 6 to 15: 22%, age 16 to 30: 22%, age 30 to 50: 9%, age ≥ 51: 7%; total does not equal 100%)
- Males/females: 140/60

### Interventions

| Group | Description |
|-------|-------------|
| A     | Permethrin 5% cream overnight, single application from neck to toes in all family members (n = 50 participants) |
| B     | Oral ivermectin 200 µg/kg body weight d1 and d14 (n = 50 participants) |
| C     | Gamma benzene hexachloride 1% for 2 consecutive overnight applications to all family members (n = 50 participants) |
| D     | White soft paraffin in a manner similar to group A (n = 50 participants) |

### Outcomes

- "Improvement clinically" (no definition; week 4)

### Funding source

Quote: "Source of Support: None"

### Declarations of interest

Quote: "Conflict of Interest: None"

### Notes

Location: Kolkata, India

We contacted first author twice via e-mail but did not receive a response.

### Risk of bias

| Bias | Authors' judgement | Support for judgement |
|------|--------------------|-----------------------|
| Random sequence generation (selection bias) | Unclear risk | Quote: "randomly distributed" |
| Allocation concealment (selection bias) | Unclear risk | Insufficient information |
| Blinding of participants and personnel (performance bias) Efficacy | High risk | No information |
| Blinding of participants and personnel (performance bias) Safety | High risk | No information |
| Blinding of outcome assessment (detection bias) | High risk | No information |
### Das 2006 (Continued)

#### Efficacy

|                         | High risk | No information |
|-------------------------|-----------|----------------|
| Blinding of outcome assessment (detection bias) Safety |           |                |
| Incomplete outcome data (attrition bias) Efficacy | High risk | Percentage of "improved clinically" reported, no definition. Results for groups C and D not reported. |
| Incomplete outcome data (attrition bias) Safety | Unclear risk | Quote: "We however did not experience any adverse effect in all four groups." Unclear number of evaluated completers |
| Selective reporting (reporting bias) | Unclear risk | Insufficient information |
| Other bias | Unclear risk | - |

### Macotela-Ruiz 1996

#### Methods

- Single-centre, parallel-group randomized trial
- Duration: 3 years, from January 1993 to December 1995

#### Participants

- **Inclusion criteria**
  - Scabies (indisputable, no information about methods of diagnosing scabies)
  - No age limit

- **Exclusion criteria**
  - Pregnant or lactating women
  - People with renal or hepatic insufficiency
  - People with antiscabietic treatment in 6 weeks prior to study

- **Baseline characteristics**
  - Age (mean): group A: male: 12, female: 16; B: male: 18, female: 20
  - Males/females: group A: 56/96, B: 53/32; unclear data, sum of males and females does not correspond to total number of included participants

#### Interventions

- A: Oral ivermectin 250 µg/kg body weight on day 1 (n = 152 participants)
- B: Oral ivermectin 250 µg/kg body weight on day 1, 3, and 10 (n = 121 participants)
  - 9 participants in group A and 10 participants in group B with secondary infection received dicloxacillin 75 mg/kg body weight per day.
  - 95 healthy contacts received an oral single dose of 250 µg/kg body weight ivermectin.

#### Outcomes

- Cure (considerable improvement of dermatosis, no pruritus, no new lesions; up to 45 days)

#### Funding source

- Not stated

#### Declarations of interest

- Not stated

#### Notes

- Location: Santiago Yancuitlalpan, Mexico
### Macotela-Ruiz 1996 (Continued)

#### Risk of bias

| Bias                                          | Authors' judgement | Support for judgement                        |
|-----------------------------------------------|--------------------|-----------------------------------------------|
| Random sequence generation (selection bias)   | Unclear risk       | Quote (page 179): "patients were randomized in two groups" |
| Allocation concealment (selection bias)       | Unclear risk       | Insufficient information                      |
| Blinding of participants and personnel (performance bias) Efficacy | High risk | Quote (page 179): "An open therapeutic study" Not blinded |
| Blinding of participants and personnel (performance bias) Safety | High risk | Quote (page 179): "An open therapeutic study" Not blinded |
| Blinding of outcome assessment (detection bias) Efficacy | High risk | Quote (page 179): "An open therapeutic study" Not blinded |
| Blinding of outcome assessment (detection bias) Safety | High risk | Quote (page 179): "An open therapeutic study" Not blinded |
| Incomplete outcome data (attrition bias) Efficacy | High risk | No information on dropouts, unclear time point of evaluation, no absolute numbers |
| Incomplete outcome data (attrition bias) Safety | High risk | No information on dropouts, unclear time point of evaluation, no absolute numbers |
| Selective reporting (reporting bias)          | High risk          | No data on defined outcomes such as pruritus, papules, excoriation, crusts, etc. |
| Other bias                                    | Unclear risk       | -                                             |

### Manjhi 2014

#### Methods

Single-centre, parallel-group randomized trial

Duration: 1 year, from April 2011 to March 2012

#### Inclusion criteria

- Age above 5 and below 60 years
- People of both sexes
- People willing to receive either topical or oral therapy
- People willing to follow-up at 1st and 6th week or if any complaints in between
- Scabies (no information about methods of diagnosing)

#### Exclusion criteria

...
Pregnant and lactating women
People who were not willing to come for follow-up
Any serious systemic illness

**Baseline characteristics**
- Not stated

**Interventions**
- A: Oral ivermectin 200 μg/kg body weight, single dose (n = 60 participants)
- B: Permethrin 5% cream, single application below the jaw line after scrub bath and left overnight (n = 60 participants)
- Not included in this review:
  - C: Gamma benzene hexachloride 1% lotion, single application (n = 60 participants)
  - D: Benzyl benzoate 25% lotion, single application (n = 60 participants)

**Outcomes**
- Complete improvement based on severity of pruritus or lesions (lesion count: < 10 - mild, 11 to 49 - moderate, > 50 - severe; pruritus: 10-centimetre visual analogue scale: 0 - no pruritus, 1 to 3 - mild, 4 to 6 - moderate, 7 to 10 - severe; week 1 and 6)
- Number of participants withdrawn from study due to adverse event

**Funding source**
- Not stated

**Declarations of interest**
- Not stated

**Notes**
- Location: Patna, India
- Children “below 5y” were excluded; unclear if children of 5 years of age were included or excluded.
- We contacted first author twice via e-mail but did not receive a response.

**Risk of bias**

| Bias | Authors' judgement | Support for judgement |
|------|--------------------|-----------------------|
| Random sequence generation (selection bias) | Unclear risk | Quote (page 1): "simple random sampling"<br>Insufficient information |
| Allocation concealment (selection bias) | Unclear risk | Quote (page 2): "randomly allocated"<br>Insufficient information |
| Blinding of participants and personnel (performance bias) Efficacy | High risk | No information |
| Blinding of participants and personnel (performance bias) Safety | High risk | No information |
| Blinding of outcome assessment (detection bias) Efficacy | High risk | No information |
### Cochrane Database of Systematic Reviews

**Manjhi 2014** (Continued)

| Safety | Blinding of outcome assessment (detection bias) | High risk | No information |
|--------|-----------------------------------------------|-----------|----------------|
| Efficacy | Incomplete outcome data (attrition bias) | High risk | Quote (page 2): Table/Fig-1 - Table/Fig-5 |
| Safety | Incomplete outcome data (attrition bias) | High risk | Quote (page 1): "The main objective of the study is to know the efficacy and safety of Oral ivermectin in comparison to commonly used topical antiscabies drugs […]"
| Safety | | | Quote (page 3): "Oral ivermectin is well tolerated, non irritant to skin, does not show central nervous system side effects because it does not cross blood brain barrier."
| Safety | | | No information about safety issues in other treatment groups; no numerical data on safety were reported |
| Selective reporting (reporting bias) | Unclear risk | Insufficient information |
| Other bias | Unclear risk | No information on baseline data |

### Meenakshi 2014

**Methods**

Single-centre, parallel-group randomized trial

Duration: 10 months, from January to October 2011

**Participants**

**Inclusion criteria**

- Age was at least 12 years
- Newly diagnosed scabies: made on basis of history and clinical examination; presence of diffuse itching and visible lesions associated either with ≥ 2 typical locations of scabies (interdigital folds, flexor aspect of wrist and elbow, genitals, anterior axillary folds) or with a household member with itching

**Exclusion criteria**

- Pregnant or lactating females
- Any history of diabetes, hypertension, or any chronic disease
- Any psychiatric illness or neurological disorder, any other associated skin disease which can affect the study due to same presentation like atopic dermatitis, dyshidrotic eczema, insect bite reaction, etc.

**Baseline characteristics**

- Age (mean): group A: 23.55, B: 27.74, C: 28.89
- Males/females: group A: 49/21, B: 41/29, C: 51/19

**Interventions**

A: Permethrin 5% cream on day 1 and 7, applied over whole body below neck and scrub bath taken 12 hours later (n = 70 participants)

B: Oral ivermectin 200 μg/kg body weight on day 1 and 7, applied any time of day (n = 70 participants)

Not included in this review:
C: Gamma benzene hexachloride 1% lotion on day 1 and 7 applied over whole body below neck and scrub bath taken 12 hours later (n = 70 participants)

- Participants of group A and C were instructed to take warm-water bath before application of medicine and then after application of medicine next morning.
- They were advised about also treating the family members and prevention of transmission by washing all clothes and bedding that came in contact.

Outcomes

- Complete clinical cure (week 1 and 3; reduction in clinical grading score (up to grade 0 or 1) and itching grading score (up to grade 0, 1, or 2); "moderate or good improvement"):
  - Clinical grading score: scale of 0 to 3: 0 = free of lesions (no lesions), 1 = 10 or fewer lesions (mild), 2 = 11 to 49 lesions (moderate), 3 = 50 or more lesions (severe)
  - Itching grading score: participant was asked for reduction in pruritus, grading was done on given scale by the observer: scale of 0 to 4: 0 = 0% (no pruritus), 1 = 1% to 25% (mild pruritus), 2 = 26% to 50% (moderate pruritus), 3 = 51% to 75% (severe pruritus), 4 = 76% to 100% (very severe pruritus
- Number of participants with ≥ 1 adverse event

**Mushtaq 2010**

Methods

- Single-centre, parallel-group randomized trial
- Duration: not stated

Participants

**Inclusion criteria**

- Aged 2 to 60 years
- Diagnosed as having scabies on history and examination; scraping for mite was performed in cases of doubt

**Exclusion criteria**

- Pregnant and lactating females
- Immunocompromised patients
- People having bacterial, fungal, or viral infections of skin
- People receiving any treatment for systemic disorders
- People who received treatment for scabies in last 4 weeks

**Baseline characteristics** (for completers only)

- Males/females: group A: 24/20, B: 20/22

Interventions

- A: Oral ivermectin 200 μg/kg body weight as a single dose (n = 44 participants completed)
- B: Permethrin 5% cream at night on whole body for 12 hours, single application (n = 42 participants completed)
  - 100 participants randomized, number of randomized participants per study group unclear.
  - Non-responders to first treatment were given second dose at second week in their respective group.

Outcomes

- Cure of disease (no lesions; week 1, 2, and 4)
- Number of participants re-treated (week 2)
- Number of participants with ≥ 1 adverse event

Funding source

- Not stated

Declarations of interest

- Not stated

Notes

- Location: Lahore, Pakistan
- Probably baseline differences: page 229: "more patients in the ivermectin group had moderate and severe lesions as compared to permethrin group"
We contacted first author twice via e-mail but did not receive a response.

### Risk of bias

| Bias                                                                 | Authors’ judgement | Support for judgement                                                                 |
|----------------------------------------------------------------------|--------------------|----------------------------------------------------------------------------------------|
| Random sequence generation (selection bias)                         | Low risk           | Quote: "divided by using random number table into group A and group B"                  |
| Allocation concealment (selection bias)                             | Unclear risk       | Insufficient information                                                                |
| Blinding of participants and personnel (performance bias) Efficacy | High risk          | No information                                                                          |
| Blinding of outcome assessment (detection bias) Efficacy            | High risk          | No information                                                                          |
| Blinding of outcome assessment (detection bias) Safety              | High risk          | No information                                                                          |
| Incomplete outcome data (attrition bias) Efficacy                  | High risk          | 14/100 participants lost to follow-up (unclear how many in each group, probably 6 in ivermectin group, 8 in permethrin group) |
|                                                                      |                    | Quote: "14 participants lost to follow up"                                                |
|                                                                      |                    | No intention-to-treat analysis performed; number of randomized participants per study group unclear. |
| Incomplete outcome data (attrition bias) Safety                    | High risk          | 14/100 participants lost to follow-up (unclear how many in each group, probably 6 in ivermectin group, 8 in permethrin group) |
|                                                                      |                    | Quote: "14 participants lost to follow up"                                                |
|                                                                      |                    | Unclear number of randomized participants per study group                               |
| Selective reporting (reporting bias)                                | Unclear risk       | Insufficient information                                                                |
| Other bias                                                          | High risk          | Sex distribution in Table 1 seems to be reversed.                                        |
|                                                                      |                    | Probably baseline differences in severity: "more patients in the ivermectin group had moderate and severe lesions as compared to permethrin group" |
|                                                                      |                    | Inconsistent data for safety (page 229 and 300): 8 versus 7 participants with adverse events |
## Methods

**Single-centre, parallel-group randomized trial**

**Duration:** 1 year and 7 months, from November 2011 to May 2013

### Participants

**Inclusion criteria**

- Aged 5 to 15 years
- Newly diagnosed with scabies
- Diagnosed by dermatologist: people with severity score 1, 2, or 3 were eligible; assessed by counting the number of lesions and assigning a score: 0 (free of lesions - no scabies), 1 (10 or fewer lesions - mild), 2 (11 to 49 lesions - moderate), 3 (50 or more lesions - severe), 4 (crusty - very severe)
- Diagnosis confirmed by microscopic examination of mite in "many patients", by biopsy of the skin lesions in "few patients"
- Body weight > 15 kg

**Exclusion criteria**

- Abnormal liver and kidney functions, known thyroid disease, cardiac disorders, nervous system disorders, psychiatric illnesses; people with history of diabetes mellitus, hypertension, or infectious diseases
- Any concurrent medication for other illness
- Any other associated skin disease that could alter the picture of scabies, or complications of scabies like pyoderma
- Known/suspected immunocompromised individuals or parents diagnosed as HIV, having scabies with atypical presentations
- Intake of any antiscabetic treatment in the preceding 4 weeks
- Intake of topical steroid in the previous 4 weeks
- Known hypersensitivity to oral or topical preparations
- People whose family/household members or classmates have scabies at the same time
- Noncompliant people/guardians

**Baseline characteristics**

- Males/females: group A: 31/19, group B: 30/20
- Age (mean): group A: 10.5, group B: 9.6

### Interventions

**A:** Permethrin 5% cream, single application to whole body below neck, left overnight (n = 50 participants)

**B:** Oral ivermectin 200 μg/kg body weight as a single dose (n = 50 participants)

- All participants were given antipruritic or antihistaminic medication for pruritus.
- Participants who showed no signs of cure at first follow-up were given same treatment again only once.
- All family contacts received same treatment as the study participant (children < 5 years of age and pregnant women were treated with 12.5% to 25% benzyl benzoate emulsion, supplied free of cost).

### Outcomes

- **Cure** (absence of clinical lesions and no new lesions like papules, vesicles, and classical burrows suggestive of live parasite; week 1, 2, and 4)
- Number of participants re-treated (week 1)
- Number of participants with ≥ 1 adverse event

| Other bias                                     | High risk          | Inconsistent data for male/female ratio (page 55/56: 61 males/39 females; page 76: 63 males/37 females) |
|                                                |                    | Inconsistent response data in abstract and doctoral thesis; conservative approach was followed |

### Methods

**Ivermectin and permethrin for treating scabies (Review)**

- **Saqib 2012**
  - **Methods:** Single-centre, parallel-group randomized trial
  - **Duration:** not stated

- **Rohatgi 2013**
  - Abstract available, and first author provided unpublished data (doctoral thesis); not all questions were answered by contact author.
• Aged 18 to 60 years
• Confirmed diagnosis of scabies by burrow detection by ink method and microscopic evidence of Sarcoptes scabiei mite in any of its development stage or its faeces

Exclusion criteria
• Pregnant or lactating women
• Hypersensitivity to permethrin or ivermectin
• Prior use of topical or systemic scabicides in the last 4 weeks
• People on radiotherapy, steroids or other immunosuppressive drugs for any systemic or cutaneous indication
• People with any chronic debilitating disorders, neoplasias, with neurological, hepatic, or renal dysfunction

Baseline characteristics
• Age (mean ± SD): group A: 31.45 ± 9.78, B: 29.45 ± 9.72 (data from Table 1)

Interventions
A: Permethrin 5% lotion form on whole body (from neck to toe) for 10 to 12 hours followed by a bath, single application; participants received explicit written instructions about topical application (n = 60 participants)

B: Oral ivermectin 200 µg/kg body weight as a single dose, taken in the presence of the investigator (n = 60 participants)

• All participants were given antihistamines at bedtime during first week.
• Secondary infection, when present, was treated with a 7-day course of antibiotic.
• Contacts of the participants of both groups were treated at the same time with same treatment (< 5 years of age and pregnant or lactating women were treated with 5% to 10% sulphur ointment).

Outcomes
• Cure (no itching, cutaneous lesions/burrows, and microscopy; week 1 and 2)
• Number of participants withdrawn from study due to adverse event

Funding source

### Sharma 2011

**Methods**

- Single-centre, parallel-group randomized trial
- Duration: 1 year and 4 months, from December 2006 to March 2008

**Inclusion criteria**

- Age over 5 years and/or > 15 kg
- Clinically diagnosed scabies: demonstration of eggs, larva, mites/mite products, or faecal pellets by light microscopy in the scrapings from multiple representative or suspected skin lesions in 10% potassium hydroxide and/or the presence of ≥ 3 of the following clinical criteria: demonstration of burrow; presence of scabetic lesions at the classical sites; nocturnal pruritus; family history of similar illness

**Exclusion criteria**

- Pregnant and lactating women
- People with immunodeficiency or severe systemic disease or with heavily crusted or nodular lesions, secondary infection or eczematization and coexisting dermatological disease that could interfere with the diagnosis and subsequent monitoring of scabies
- Antiscabetic or topical steroid in the previous 4 weeks
- Known hypersensitivity to the trial drugs

**Baseline characteristics**

- Age (mean ± SD): group A: 21.38 ± 13.17, B: 23.40 ± 11.03, C: 23.53 ± 12.73
Males/females: group A: 19/21, B: 29/11, C: 24/16

Interventions

A: Permethrin 5% cream, self applied on day 1 and placebo tablets of vitamin B-complex on day 1 and 15 (n = 40 participants)

B: Placebo cream, self applied on day 1 and oral ivermectin 200 μg/kg body weight on day 1 and placebo tablet of vitamin B-complex on day 15 (n = 40 participants)

C: Placebo cream, self applied on day 1 and oral ivermectin 200 μg/kg body weight on day 1 and 15 (n = 40 participants)

• Participants were instructed to apply the medication all over the body below the neck at night.
• All family contacts were provided with permethrin 5% cream for single overnight application, free of cost.

Outcomes

• Complete clinical cure (defined as reduction in both the number of lesions as well as the grade of pruritus by more than or equal to 50% (that is, moderate and good improvement) and negative microscopy; week 1, 2, and 4)
• Number of participants with ≥ 1 adverse event (data for group B and C combined)

| Incomplete outcome data (attrition bias)       | Low risk           | 3/120 participants lost to follow-up (permethrin group: 2; oral ivermectin - 2 doses group: 1) No withdrawal at 1 week follow-up; no intention-to-treat analysis for week 2 and 4 |

Ivermectin and permethrin for treating scabies (Review)

Copyright © 2018 The Authors. Cochrane Database of Systematic Reviews published by John Wiley & Sons, Ltd. on behalf of The Cochrane Collaboration.
### Usha 2000

**Methods**

Single-centre, parallel-group randomized trial

Duration: 1 year and 5 months, from August 1996 to December 1997

**Participants**

**Inclusion criteria**
- Older than 5 years of age
- Scabies: diagnosed by the demonstration of eggs, larva, mites, or faecal pellets by light microscopy or by the presence of ≥ 3 of the following clinical criteria confirmed independently by 2 consultants: demonstration of burrow, presence of scabetic lesions at the classical sites, nocturnal pruritus, family history of similar illness

**Exclusion criteria**
- Pregnant and lactating women
- Any antiscabetic treatment in the previous month
- People with serious central nervous system, hepatic, cardiac, or renal disease

**Baseline characteristics**
- Age (mean ± SD): group A: 21.28 ± 13.44, B: 22.4 ± 12.6
- Males/females: group A: 26/14, B: 33/12

**Interventions**

A: Oral ivermectin 200 μg/kg body weight, single dose, supervised (n = 40 participants)

B: Permethrin 5% cream, single application overnight (n = 45 participants)

- All participants received standard instructions (about the mode of application, general measures, importance of treating the family contacts, prevention of fomite transmission).
- Participants with treatment failure (no improvement in pruritus and skin lesions, appearance of new lesions, or presence of mites or their products on microscopy) at week 2 received another dose of same treatment; at week 4 cross-over to other group.
- Secondary infection was treated with a 7-day course of erythromycin 250 mg 4 times daily.
- All family contacts received same treatment as the study participant (children < 5 years of age and pregnant women were treated with 12.5% to 25% benzyl benzoate emulsion).

**Outcomes**
- Complete clearance (good improvement; week 1, 2, 4, and 8)
- Number of participants re-treated (week 2 and 4)
- Number of participants with ≥ 1 adverse event
- Number of participants withdrawn from study due to adverse event

**Funding source**
- Not stated

**Declarations of interest**
- Not stated

Wankhade 2013

Methods
Single-centre, parallel-group randomized trial
Duration: not stated

Participants
Inclusion criteria
- People with scabies

Exclusion criteria
Baseline characteristics

Interventions

A: Permethrin 5% (type of formulation not stated; n = unclear)
B: Oral ivermectin 200 µg/kg body weight as a single dose (n = unclear)

- 100 participants were allocated.
- If there was no sign of cure, same treatment was repeated.

Outcomes

- Cure rate (no definition; time point of evaluation unclear)

Funding source

Not stated

Declarations of interest

Not stated

Wankhade 2016

Methods | Single-centre, parallel-group randomized trial
--- | ---
Duration: 1 year and 1 month, from March 2013 to March 2014

Participants

**Inclusion criteria**

- Age between 5 to 60 years
- New patients of scabies as diagnosed by dermatologist
- History of involvement of family member or similar symptoms in contacts
- Presence of nocturnal itching
- For those whose microscopic examination was negative, inclusion in study was based on clinical criteria

**Exclusion criteria**

- Pregnant and lactating women
- People with any other associated skin disease that could alter the picture of scabies, or complications of scabies like pyoderma
- Known or suspected immunocompromised individuals like HIV
- History of topical steroid use in the previous 4 weeks or use of topical or systemic antibiotic therapy in the week before entry into the study
- Received any antiscabetic treatment in the past 4 weeks
- Noncompliant participants or guardians
- People not willing to come for follow-up
- People having scabies with atypical presentation like crusted scabies or scabies incognito
- History of allergy to any of the study drugs
- People with associated comorbid condition like hypertension, diabetes, liver, kidney disorder

**Baseline characteristics**

- Age (mean ± SD): group A: 16.74 ± 9.90, B: 22.04 ± 10.61, C: 23.74 ± 9.91
- Males/females: group A: 30/20, B: 28/22, C: 29/21

**Interventions**

A: Permethrin 5% cream, single application (n = 50 participants)

B: Oral ivermectin 200 µg/kg body weight, single application (n = 50 participants)

Not included in this review:

C: Combination of topical permethrin with oral ivermectin (n = 50 participants)

- If there were no signs of cure, the same intervention was repeated at the end of week 1 only once.

**Outcomes**

- Cure (no new clinical lesions and improvement in pruritus, no new lesions like papules, vesicles, and classical burrows suggestive of live parasite should be seen; week 1 and 4)
**Wankhade 2016 (Continued)**

- Number of participants with ≥ 1 adverse event
- Number of participants withdrawn due to adverse event

### Characteristics of ongoing studies [ordered by study ID]

**NCT02407782**

- **Trial name or title**: Oral Ivermectin Versus Topical Permethrin to Treat Scabies in Children (SCRATCH)
- **Methods**: Multicentre, randomized trial
  Duration: 1 year and 9 months, from January 2016 to September 2017 (estimated)
- **Participants**
  - **Inclusion criteria**
    - Children up to 16 years of age
    - Weight > 15 kg
    - Documented diagnosis of scabies, defined by positive dermoscopic examination
  - **Exclusion criteria**
    - Previous scabies therapy during the past 4 weeks
    - Known allergy to ivermectin or permethrin
    - Widespread eczematization or impetiginization
    - Liver and renal failure
- **Interventions**
  - A: Permethrin 5% cream on day 1 and 10
  - B: Oral ivermectin 200 μg/kg body weight on day 1 and 10
  - Estimated enrolment: 502 participants
- **Outcomes**
  - Assessment of skin lesions and healing at day 28
- **Starting date**: January 2016
- **Contact information**
  - Franck BORALEVI, Professor 05 56 79 59 41 franck.boralevi@chu-bordeaux.fr
  - Fabienne NACKA, PhD 05 57 82 01 08 fabienne.nacka@chu-bordeaux.fr
- **Study ID**
  - Clinical trial registry: NCT02407782
  - Other study ID number: CHUBX 2011/16
- **Notes**
  - Location: Bordeaux, France
### DATA AND ANALYSES

#### Comparison 1. Ivermectin 200 μg/kg (1 to 3 doses) versus permethrin 5% cream (1 to 3 applications)

| Outcome or subgroup title                                      | No. of studies | No. of participants | Statistical method                | Effect size         |
|---------------------------------------------------------------|----------------|---------------------|-----------------------------------|---------------------|
| 1 Complete clearance - week 1                                 | 6              | 613                 | Risk Ratio (M-H, Random, 95% CI)  | 0.65 [0.54, 0.78]   |
| 2 Complete clearance - week 2                                 | 5              | 459                 | Risk Ratio (M-H, Random, 95% CI)  | 0.91 [0.76, 1.08]   |
| 3 Complete clearance - week 4                                 | 6              |                      | Risk Ratio (M-H, Random, 95% CI)  | Subtotals only      |

**Abbreviations:** IVER: ivermectin; PER: permethrin.

### Appendix 4. Definition and diagnosis of complete clearance

| Study               | Name of outcome | Definition and evaluation                                                                 |
|---------------------|-----------------|-------------------------------------------------------------------------------------------|
| Abdel-Raheem 2016   | Complete cure   | • Negative parasitological examination with complete absence of new lesions               |
|                     |                 | • residual and all new lesions were scraped for detection of mites                       |
|                     |                 | • if only one mite was detected, this was considered as treatment failure                |
| Ahmad 2016          | Cure            | • Clinical assessment by 1 researcher                                                     |
|                     |                 | • 4-point scale for lesion count: 0 = no skin lesions; 1 = ≤ 10 lesions; 2 = 11 to 49 lesions; 3 ≥ 50 lesions |
|                     |                 | • 4-point scale for pruritus: 0 = no pruritus; 1 = mild pruritus; 2 = moderate pruritus; 3 = marked pruritus |
|                     |                 | • cure = 0                                                                                |
|                     |                 | • laboratory diagnosis: demonstration of mites and/or mite products (eggs, larva, or faecal pellets) in scrapings from skin lesions (burrows or scabetic papules from classical sites: finger webs, flexural aspect of wrist, or penile shaft) using light microscopy after incubation in 15% potassium hydroxide |
| Bachewar 2009       | Cure            | • No new lesions papules, vesicles, and classical burrows                                 |
|                     |                 | • examined by dermatologist and principal investigator to standardize clinical evaluation |
| Chhalya 2012        | Clinical cure of scabetic lesions          | • No definition                                                                           |
| Das 2006            | Improvement clinically | • No definition                                                                           |
| Macotela-Ruiz 1996  | Cure            | • Considerable improvement of dermatosis, no pruritus, no new lesions                    |
| Manjhi 2014         | Complete improvement | • Based on severity of pruritus or lesions                                                  |
|                     |                 | • lesion count: < 10: mild, 11 to 49: moderate, > 50: severe                              |
|                     |                 | • pruritus on 10-centimetre visual analogue scale: 0 - no pruritus, 1 to 3 - mild, 4 to 6 - moderate, 7 to 10 - severe |
|                     |                 | • complete improvement not defined                                                        |
| Meenakshi 2014      | Complete clinical cure | • Reduction in clinical grading score up to grade 0 or 1 and reduction in itching grading score up to grade 0, 1, or 2; “moderate or good improvement” |
|                     |                 | • clinical grading score: 0 = free of lesions (no lesions), 1 = 10 or fewer lesions (mild), 2 = 11 to 49 lesions (moderate), 3 = 50 or more lesions (severe) |
|                     |                 | • itching grading score: participant was asked for reduction in pruritus, grading was done on given scale by the observer: 0 = 0% (no pruritus), 1 = 1% to 25% (mild pruritus), 2 = 26% to 50% (moderate pruritus), 3 = 51% to 75% (severe pruritus), 4 = 76% to 100% (very severe pruritus) |
| Mushtaq 2010        | Cure of disease | • No lesions                                                                             |
| Rohatgi 2013        | Cure            | • Absence of clinical lesions and no new lesions like papules, vesicles, and classical burrows suggestive of live parasite |
| Saqib 2012          | Cure            | • No itching, cutaneous lesions/burrows, and negative microscopy                         |
Sharma 2011 Complete clinical cure
- Reduction in both the number of lesions and the grade of pruritus by more than or equal to 50% (that is, moderate and good improvement) and negative microscopy

Usha 2000 Complete clearance
- Good improvement

Wankhade 2013 Cure rate
- No definition

Wankhade 2016 Cure
- No new clinical lesions and improvement in pruritus, no new lesions like papules, vesicles, and classical burrows suggestive of live parasite seen

CONTRIBUTIONS OF AUTHORS
SR was the contact person with the editorial base, co-ordinating the contributions from the co-authors; sought additional information about papers; entered data into RevMan 5 (RevMan 2014); worked on the Methods section; updated the clinical sections of the Background based on the Cochrane Review ‘Interventions for treating scabies’ by Mark Strong and Paul Johnstone (Strong 2007). SR screened all hits using the inclusion/exclusion criteria; screened reference lists of included studies for additional randomized controlled trials; independently extracted data using the standardized form; performed the 'Risk of bias' evaluation for all included trials; analysed and interpreted data; wrote the final draft of the review.

CD screened all hits using the inclusion/exclusion criteria and independently extracted data using the standardized form; performed the 'Risk of bias' evaluation for all included trials. CD discussed data analysis strategies with SR and checked the data entered into Review Manager 5. CD also contributed substantially to writing the Cochrane Review.

SR and CD performed the GRADE assessment of all comparisons.

SR, CD, and AN jointly finalized the review. AN was solely responsible for the medical input and the 'Implications for practice' section.

DECLARATIONS OF INTEREST
SR and CD have no conflicts of interest. CD, SR, and AN previously published a systematic review on scabies treatments (Dressler 2016a).

CD is a member of the Cochrane Scientific Committee.

AN is a member of the expert panel of the German consensus-based guideline for the diagnosis and treatment of scabies published in January 2016 (AWMF (Arbeitsgemeinschaft der Wissenschaftlichen Medizinischen Fachgesellschaften e.V.), Association of the Scientific Medical Societies in Germany; register number: 013-052).

DIFFERENCES BETWEEN PROTOCOL AND REVIEW
We have changed the secondary outcome ‘number of patients requiring re-treatment' to ‘number of participants re-treated'. We found this to be a more suitable outcome measure considering our research question.

In case of inconsistent or implausible outcome data within a publication, we asked the corresponding author for clarification, irrespective of the date of publication.

We clarified in the Types of participants section that we only included studies investigating people with classical scabies.
INDEX TERMS

Medical Subject Headings (MeSH)
Administration, Oral; Administration, Topical; Antiparasitic Agents [administration & dosage] [*therapeutic use]; Ivermectin [administration & dosage] [*therapeutic use]; Permethrin [administration & dosage] [*therapeutic use]; Randomized Controlled Trials as Topic; Scabies [*drug therapy]; Treatment Outcome
