It is shown that the polarizations of the final particles in $\mu^+ \rightarrow e^+ e^- e^+$ provide us with information on the CP-violating phases of the effective Lagrangian leading to this Lepton Flavor Violating (LFV) decay.

PACS numbers: 11.30.Hv, 13.35.Bv
Keywords: Lepton Flavor, Muon decay, CP-violation, angular distribution

I. INTRODUCTION

In the context of the “old” Standard Model (SM) with zero neutrino masses, the lepton flavor is conserved. As a result, the LFV decays such as $\mu \rightarrow eee$ and $\mu \rightarrow e\gamma$ are strictly forbidden within the “old” SM. Within the “new” SM with sources of LFV in the neutrino mass matrix, such decays are in principle allowed but their rates are suppressed by powers of the neutrino mass and are therefore beyond the reach of any searches in the foreseeable future \cite{1}. However, a variety of beyond SM scenarios can lead to rates for these processes exceeding the present experimental bounds \cite{2}:

$$\text{Br}(\mu \rightarrow e\gamma) < 1.2 \times 10^{-11} \quad \text{and} \quad \text{Br}(\mu^{-} \rightarrow e^{-} e^{+} e^{-}) < 1.0 \times 10^{-12}. \quad (1)$$

Notice that the bound on $\mu \rightarrow eee$ is even stronger than the famous bound on $\mu \rightarrow e\gamma$. In the context of models like R-parity conserving MSSM in which the new particles can appear only in even numbers in each vertex, these processes can only take place at the loop level. Since $\mu \rightarrow eee$ is a three body decay, in such a model, $\text{Br}(\mu \rightarrow eee)$ is suppressed relative to $\text{Br}(\mu \rightarrow e\gamma)$ by a factor typically of order of $e^{2}/(16\pi^{2}) \log(m_{\mu}/m_{e})$ \cite{3}. However, in the models that new particles can appear in odd numbers at each vertex (e.g., in R-parity violating MSSM) the process $\mu \rightarrow eee$ can take place at tree level and as a result, its rate can even exceed that of $\mu \rightarrow e\gamma$ \cite{4}.

It is rather well-known that by measuring the angular distribution of the final particles relative to the spin of the initial muon in $\mu \rightarrow e\gamma$ and $\mu \rightarrow eee$, one can derive information on the chiral nature of the effective Lagrangian leading to this process \cite{4, 5, 6}. In the case of $\mu \rightarrow eee$, as shown in the literature \cite{5, 7, 8}, the angular distribution of the final particles relative to the spin of the initial muon also yields information on certain combinations of the CP-violating phases.

Recently, it has been shown in \cite{4, 10, 11} that if we measure the polarization of the emitted particles in $\mu \rightarrow e\gamma$ and $\mu N \rightarrow e N$, we can derive information on the CP-violating parameters of the theory. It was pointed out in \cite{9, 10} that by measuring the spin of the more energetic final positron in $\mu^+ \rightarrow e^+ e^- e^+$, some information on the CP-violating phases can be derived. The analysis was performed in the framework of the models such as $R$-parity conserving MSSM, in which the dominant contribution to $\mu \rightarrow eee$ comes from a penguin diagram (i.e., $\mu^+ \rightarrow \gamma^* e^+ e^- \rightarrow e^+ e^- e^+$). In this letter, we focus on the case that $\mu^+ \rightarrow e^+ e^- e^+$ happens at the tree level through the exchange of heavy particles. We show that the transverse polarizations of the emitted particles in $\mu^+ \rightarrow e^+ e^- e^+$ provide us with information on the CP-violating properties of the effective Lagrangian. The information derived from the spins of the emitted electrons and positrons are complementary to each other. In this letter, we focus on $\mu^+ \rightarrow e^+ e^- e^+$. Similar arguments hold for $\mu^- \rightarrow e^- e^+ e^-$. We show that the method proposed here is sensitive to a combination of the phases in the effective Lagrangian which is different from those that can be derived by methods discussed in the literature \cite{4, 5, 7, 8}. The effectiveness of each method depends on the relative magnitude of the different terms in the effective Lagrangian which in turn depends on the details of the underlying model.

II. THE RATE OF $\mu^+ \rightarrow e^+ e^-$

Consider a general beyond SM scenario leading to $\mu^+ \rightarrow e^+ e^- e^-$. After integrating out the heavy states, the effect can be described by an effective Lagrangian of form

$$\mathcal{L} = \mathcal{L}_1 + \mathcal{L}_2$$

where

$$\mathcal{L}_1 = B_1(\bar{\mu} \gamma^\nu e \gamma^\mu_\nu e + \bar{\mu} \gamma^\nu e \gamma^\mu_\nu e) + C_1(\bar{\mu} \gamma^\nu e \gamma^\mu_\nu e) + G_1(\bar{\mu} \gamma^\nu e \gamma^\mu_\nu e) + G_2(\bar{\mu} \gamma^\nu e \gamma^\mu_\nu e) + \text{H.c.}$$

$$\mathcal{L}_2 = A_L \bar{\mu} [\gamma^\mu, \gamma^\nu e \gamma^\mu_\nu e] + A_R \bar{\mu} [\gamma^\mu, \gamma^\nu e \gamma^\mu_\nu e] + \text{H.c.}$$

Notice that by using the identities $(\sigma^\mu)_{\alpha\beta} (\sigma^\mu)_{\gamma\delta} = 2 \epsilon_{\alpha\gamma} \epsilon_{\beta\delta}$ and $(\bar{\sigma}^\mu)_{\alpha\beta} = \epsilon_{\beta\delta} (\sigma^\mu)_{\delta\gamma} (\epsilon_{\alpha\gamma} (\text{where } \epsilon_{11} = \epsilon_{00} = 0 \text{ and } \epsilon_{10} = -\epsilon_{01} = 1)$ and employing the fact that the fermions anti-commute, we can rewrite the terms on the first line of Eq. (3) as

$$-\frac{B_1}{2} (\bar{\mu} \gamma^\nu e \gamma^\mu_\nu e) + \frac{B_2}{2} (\bar{\mu} \gamma^\nu e \gamma^\mu_\nu e).$$

In the literature, it has been shown that by studying the angular distribution of the final particles relative to the spin of the initial muon, one can derive information on $\text{Re}[A_L B_1 - A_L B_2]$, $\text{Re}[A_R G_2 - A_L G_1]$, $\text{Im}[A_R B_1 + A_L B_2]$ and $\text{Im}[A_R G_2 + A_L G_1]$ (see e.g., [4, 7, 8]). However, by this method the phases of $C_1$ and $C_2$ cannot be derived. Moreover, if $A_L$ and $A_R$ are zero or suppressed, this method loses its effectiveness.

By studying the energy spectrum of the emitted particles, it will be possible to differentiate between the different terms in $\mathcal{L}_1$ and $\mathcal{L}_2$. For example, the $A_L$ and $A_R$ couplings lead to a sharp peak in the distribution of the square of the invariant mass of a $e^- e^+$ pair [i.e., in the distribution of $(P_e^- - P_e^+)^2$ at $(m_e^2/2)^2]$. Such a peak does not appear if the dominant contribution comes from Eq. (3). The $A_L$ and $A_R$ couplings are generally loop suppressed but, as we see below, terms in $\mathcal{L}_1$ can appear in a wide range of models at tree level. In the present letter, we only consider terms in $\mathcal{L}_1$.

The $B_i$ and $C_i$ couplings in $\mathcal{L}_1$ can originate from the exchange of a heavy neutral scalar field (or fields). Let us demonstrate this through a simple toy model. Consider two heavy complex fields, $\phi_1$ and $\phi_2$ with the following couplings

$$g_{\mu L} \phi_1 \phi_2 \frac{1 + \gamma_5}{2} e + g_{\mu R} \phi_2 \phi_1 \frac{1 - \gamma_5}{2} e + g_{e L} \phi_1 e \frac{1 + \gamma_5}{2} e + g_{e R} \phi_2 e \frac{1 - \gamma_5}{2} e + \text{H.c.}$$

It is straightforward to show that the effective Lagrangian resulting from integrating out the heavy states $\phi_1$ and $\phi_2$ is of form (3) with

$$B_1 = \frac{g_{\mu L} g_{e L}^*}{m_{\phi_1}^2}, \quad B_2 = \frac{g_{\mu R} g_{e R}^*}{m_{\phi_2}^2}, \quad C_1 = C_2 = 0.$$
where \( \eta \) is a pure phase that comes from the freedom in the definition of the CP-conjugate of the electron and the muon. By rephasing the electron and/or the muon field, either of these couplings can be made real. Thus, the Lagrangian in Eq. (3) contains five physical CP-violating phases.

From the formulas derived in the appendix, we find that the differential decay rate of \( \mu^+ \to e^+ e^- e^+ \) is

\[
\int_{0}^{2\pi} \sum_{\vec{s}_e-\vec{s}_e^+} \frac{d^3\Gamma(\mu^+ \to e^+_1 e^- e^+_2)}{dE_e \, dE_{e_1} \, d\Omega} \, d\phi_+ = \frac{1}{128\pi^3} \left[ (|B_1|^2 + |B_2|^2)(-m_\mu^2 + 4m_\mu^2E_e - 2E_e^2m_\mu - 4m_\muE_{e_1}^2 - 4m_\muE_eE_{e_1}^+ \right)
\]

\[
+ (|B_1|^2 - |B_2|^2)\mathbb{P}_\mu \cos \theta_-(m_\mu^4 - 4m_\mu^2E_e - 3m_\mu^2E_{e_1} - 3m_\muE_{e_1}^2 + 8m_\muE_eE_{e_1}^+ + 4m_\muE_{e_1}^2 + 4m_\muE_{e_1}^2 - 2m_\muE_eE_{e_1}^+) \big/ E_e
\]

\[
+ \left[ (|C_1|^2 + 16|G_2|^2)(1 + \mathbb{P}_\mu \cos \theta_-) + (|C_2|^2 + 16|G_1|^2)(1 - \mathbb{P}_\mu \cos \theta_-) \right] E_e m_\mu(m_\mu - 2E_e) \big/ E_e \]

where \( d\Omega \) is the differential solid angle determining the orientation of the emitted electron. We have summed over the spins of the final particles and integrated over \( \phi_+ \), which determines the azimuthal angle of the emitted positrons (see Fig. 1).

Integrating over the energies of the final particles, we find

\[
\sum_{\vec{s}_e-\vec{s}_e^+} \frac{d\Gamma}{d\cos\Omega} = \frac{0.0208}{128\pi^4} m_\mu^5 \left[ (|B_1|^2 + |B_2|^2 + |C_1|^2 + |C_2|^2/2 + 8|G_1|^2 + 8|G_2|^2)
\]

\[
+ \mathbb{P}_\mu \cos \theta_- (|B_2|^2 - |B_1|^2/3 + |C_1|^2 - |C_2|^2/2 + 8(|G_2|^2 - |G_1|^2)) \big/ \right]

(6)

The total rate of \( \int (d\Gamma / d\Omega) d\Omega \) is given by \( (|B_1|^2 + |B_2|^2 + (|C_1|^2 + |C_2|^2)/2 + 8(|G_1|^2 + |G_2|^2) \). From the bound on \( \text{Br}(\mu \to eee) \) (see Eq. 1), we find

\[
|B_1|^2 + |B_2|^2 + \frac{|C_1|^2 + |C_2|^2}{2} + 8(|G_1|^2 + |G_2|^2) < \frac{1}{(200 \text{ TeV})^4}.
\]

From Eq. (6), we observe that the dependence of the coefficients of \( |B_1|^2 + |B_2|^2 \) and \( |C_1|^2 + |C_2|^2 + 16(|G_1|^2 + |G_2|^2) \) on \( E_{e_1}^+ \) and \( E_e \) are different. As a result, by studying the energy spectrum of the final particles, it will be possible to extract \( |B_1|^2 + |B_2|^2 \) and \( |C_1|^2 + |C_2|^2 + 16(|G_1|^2 + |G_2|^2) \). If in addition to the energy spectrum, the angular distribution of the electron relative to \( \vec{s}_\mu \) is measured, it will be possible to extract the parity violating combinations \( |B_1|^2 - |B_2|^2 \) and \( |C_1|^2 - |C_2|^2 + 16(|G_2|^2 - |G_1|^2) \). Of course the larger the polarization of the initial muon, the higher the sensitivity of the angular distribution to these combinations. Thus, in principle by measuring the spectrum of the emitted particles and angular distribution of the final electron, it will be possible to derive the absolute
values of the couplings. The angular distribution of the final positrons also give information on \(|B_1|^2 - |B_2|^2\) and \(|C_1|^2 - |C_2|^2 + 16(|G_2|^2 - |G_1|^2)|\) (see the appendix). Thus, the following combinations can be measured from the study of the angular distribution plus energy spectrum measurements:

\[ |B_1|^2, \ |B_2|^2, \ |C_1|^2 + 16|G_2|^2 \] and \(|C_2|^2 + 16|G_1|^2| \). \hfill (7)

However, without sensitivity to the spins of the final particles, it is not possible to derive information on the phases of the couplings. In sect. \textbf{A} we explore what can be learned from the polarization of the emitted electron. In sect. \textbf{III} we discuss the polarization of the positron.

### A. Polarization of the emitted electron

Consider the decay \(\mu^+ \to e^+ e^- e^+\) in the rest frame of the muon, where the final electron makes an angle of \(\theta_+\) with the spin of the initial muon. Let us take the \(\hat{T}_3\) direction parallel to the momentum of the emitted electron and \(\hat{T}_2 \equiv \hat{T}_3 \times \hat{s}_\mu / |\hat{T}_3 \times \hat{s}_\mu|\) (see Fig. 1). The spin of the electron is determined by \((c_{e^-}, d_{e^-})\) with \(|(c_{e^-})^2 + |d_{e^-}|^2|^{1/2} = 1\). That is, the components of the spin of the electron are

\[ \hat{T}_3 \cdot \hat{s}_- = |c_{e^-}|^2 - |d_{e^-}|^2, \quad \hat{T}_1 \cdot \hat{s}_- = 2 \text{Re}[c_{e^-}^* d_{e^-}] \text{ and } \hat{T}_2 \cdot \hat{s}_- = 2 \text{Im}[c_{e^-}^* d_{e^-}]. \] \hfill (8)

From the formulas in the appendix, we find that the differential decay rate in the rest frame of the muon is

\[
\sum_{s_{e^+}^-, s_{e^-}^+} \frac{d\Gamma(\mu^+ \to e^+ e^- e^+)}{d \cos \Omega} = \int_0^{2\pi} \int_0^{\frac{m_\mu}{m_\mu - 2E_e}} \sum_{s_{e^-}^-, s_{e^-}^+} |M|^2 E_{e^+} E_e (m_\mu - E_{e^+} - E_e) dE_{e^+} dE_e d\phi_+ \]

\[
= \frac{m_\mu^5}{128\pi^4} \left[ (0.0208) [(|B_1|^2|c_{e^-}|^2 + |B_2|^2|d_{e^-}|^2 + (|C_1|^2/2 + 8|G_2|^2)|d_{e^-}|^2 + (|C_2|^2/2 + 8|G_1|^2)|c_{e^-}|^2] \right. \]

\[
+ \left. (0.0208) \mathbb{P}_\mu \cos \theta_- |B_2|^2 |d_{e^-}|^2 - (|B_1|^2 |c_{e^-}|^2/3 + (|C_1|^2/2 + 8|G_2|^2)|d_{e^-}|^2 - (|C_2|^2/2 + 8|G_1|^2)|c_{e^-}|^2] \right]

\[
- (0.0832) \mathbb{P}_\mu \sin \theta_- (\text{Re}[G_1 C_1^* e_{e^-}] + \text{Re}[G_2 C_2 d_{e^-}]) \right]

\[
+ 0.055 \text{Re}[B_1 B_2^* d_{e^-} c_{e^-}^*] \mathbb{P}_\mu \sin \theta_-, \]

where \(\mathbb{P}_\mu\) is the polarization of the initial muon and \(d\Omega\) represents the differential solid angle of the momentum of the electron relative to the spin of the muon. To obtain this equation, we have summed over the spins of the emitted positrons and integrated over the azimuthal angle that the plane containing the momenta of these positrons makes with the plane of the spin of the anti-muon and the momentum of the electron. See the appendix for the details. Notice that there is no interference term between the chirality-flipping and chirality-conserving couplings.

From Eq. (21) in the appendix, we find that the longitudinal polarization of the electron is

\[
\langle s_{T_3^-} \rangle = \frac{d\Gamma/d\Omega|_{c_{e^-}=1, d_{e^-}=0} - d\Gamma/d\Omega|_{c_{e^-}=0, d_{e^-}=1}}{d\Gamma/d\Omega|_{c_{e^-}=1, d_{e^-}=0} + d\Gamma/d\Omega|_{c_{e^-}=0, d_{e^-}=1}} = \frac{P_1^- - \mathbb{P}_\mu \cos \theta_- P_2^-}{P_3^- + \mathbb{P}_\mu \cos \theta_- P_4^-}, \]

where

\[
P_1^- = |B_1|^2 - |B_2|^2 - \frac{|C_1|^2}{2} + \frac{|C_2|^2}{2} + 8|G_1|^2 - 8|G_2|^2 \]

\[
P_2^- = \frac{|B_1|^2}{3} + \frac{|B_2|^2}{3} + \frac{|C_1|^2}{2} + \frac{|C_2|^2}{2} + 8|G_1|^2 + 8|G_2|^2 \]

\[
P_3^- = |B_1|^2 + |B_2|^2 + \frac{|C_1|^2}{2} + \frac{|C_2|^2}{2} + 8|G_1|^2 + 8|G_2|^2 \]

\[
P_4^- = -\frac{|B_1|^2}{3} + \frac{|B_2|^2}{3} + \frac{|C_1|^2}{2} - \frac{|C_2|^2}{2} - 8|G_1|^2 + 8|G_2|^2. \] \hfill (11)

\(\langle s_{T_3^-} \rangle\) is sensitive only to the absolute values of the couplings. Notice that by measuring \(\langle s_{T_3^-} \rangle\) and its angular distribution, one can derive the same combinations that are listed in Eq. (7) \(i.e.,\) the combinations that can be extracted from the angular distribution and energy spectrum (without measuring the spin of the final particles). Derivation of these combinations from the measurement of \(\langle s_{T_3^-} \rangle\) can be considered as a cross-check for the derivation from the energy spectrum. Notice that even in the \(\mathbb{P}_\mu = 0\) limit, \(\langle s_{T_3^-} \rangle\) is still non-vanishing and provides us with
information on the parity violating combination $P_3$. That is while in this limit, the angular distribution of the electron is uniform and has no sensitivity to parity violation in the effective Lagrangian (3) (see Eq. (5)).

The transverse polarizations are

$$\langle s_{T_1^-} \rangle \equiv \frac{d\Gamma/d\Omega|_{e_+=-i/\sqrt{2}} - d\Gamma/d\Omega|_{e_+=-i/\sqrt{2}}}{d\Gamma/d\Omega|_{e_+=-i/\sqrt{2}} + d\Gamma/d\Omega|_{e_+=-i/\sqrt{2}}} = \text{Re} \left[ \frac{(2.6)B_1^2B_2 - 4G_1^2C_1 - 4G_2C_2^*] \sin \theta - P_\mu}{P_3 - P_4 P_\mu \cos \theta_-} \right] \quad (12)$$

and

$$\langle s_{T_2^-} \rangle \equiv \frac{d\Gamma/d\Omega|_{e_+=-i/\sqrt{2}} - d\Gamma/d\Omega|_{e_+=-i/\sqrt{2}}}{d\Gamma/d\Omega|_{e_+=-i/\sqrt{2}} + d\Gamma/d\Omega|_{e_+=-i/\sqrt{2}}} = \text{Im} \left[ \frac{(2.6)B_1^2B_2 - 4G_1^2C_1 - 4G_2C_2^*] \sin \theta - P_\mu}{P_3 - P_4 P_\mu \cos \theta_-} \right] \quad (13)$$

The transverse polarizations are maximal for electrons emitted in the direction perpendicular to the spin of the muon: i.e., $\theta_- = \pi/2$. Notice that $\langle s_{T_1^-} \rangle$ and $\langle s_{T_2^-} \rangle$ provide independent information on the real and imaginary parts of the same combination; i.e., $(2.6)B_1^2B_2 - 4G_1^2C_1 - 4G_2C_2^*]$. Notice that both the moduli and the phase of this combination contain extra information beyond the combinations listed in Eq. (7). In the context of various models $G_i$ and $C_i$ can vanish. For example, as explained in the previous section, if the effective Lagrangian comes from integrating out neutral scalars, the $G_i$ couplings will vanish. Within such models, $\langle s_{T_1^-} \rangle \propto \text{Re}[B_1B_2^*]$ and $\langle s_{T_2^-} \rangle \propto \text{Im}[B_1B_2^*]$. Considering that $|B_1|$ can be independently measured, the derivation of $\arg[B_1B_2^*]$ from both $\langle s_{T_1^-} \rangle$ and $\langle s_{T_2^-} \rangle$ can be considered as a cross-check.

In the limit of unpolarized muon (i.e., $P_\mu \to 0$), $\langle s_{T_1^-} \rangle$ and $\langle s_{T_2^-} \rangle$ vanish. This is understandable because in the $P_\mu = 0$ limit, there is no preferred directions so we cannot define $\hat{T}_1^- \equiv \hat{T}_3^+ \times s_\mu/|\hat{T}_3^+ \times s_\mu|$ (see Fig. [F]). Thus, to derive the CP-violating phase, $\arg[B_1B_2^*]$, it is necessary to have a source of polarized muon which is quite feasible. For example if the muons are produced by the decay of pions at rest, they will be almost 100% polarized. In fact, this is the case for the on-going MEG experiment.

By measuring the polarization of the emitted electron, it is not possible to derive the values of all the CP-violating phases of the Lagrangian (3). Measurement of the angular distribution of the positrons does not provide any further information. As we shall see next, the transverse polarizations of the emitted positrons provide complementary information on the phases.

**B. Polarization of the positron**

Consider the decay $\mu^+ \to e_1^+ e_2^-$ in the rest frame of the muon where one of the final positrons makes an angle of $\theta_+$ with the spin of the initial muon. Let us take the $T_3^+$ direction parallel to the momentum of $e_1^+$ and $\hat{T}_2^+ \equiv \hat{T}_3^+ \times s_\mu/|\hat{T}_3^+ \times s_\mu|$ (see Fig. [F]). The spin of $e_1^+$ is determined by $(c_{e_1^+} d_{e_1^+})$ with $(|c_{e_1^+}|^2 + |d_{e_1^+}|^2)^{1/2} = 1$. The components of the spin are

$$\hat{T}_3^+ \cdot \hat{s}_{e_1^+} = |c_{e_1^+}|^2 - |d_{e_1^+}|^2, \quad \hat{T}_1^+ \cdot \hat{s}_{e_1^+} = 2\text{Re}[c_{e_1^+}^* d_{e_1^+}] \quad \text{and} \quad \hat{T}_2^+ \cdot \hat{s}_{e_1^+} = 2\text{Im}[c_{e_1^+}^* d_{e_1^+}] \quad (14)$$

From the formula in the appendix, we find that the differential decay rate in the rest frame of the muon is

$$\sum \int_{\hat{s}_{e_1^+}} \frac{d\Gamma (\mu^+ \to e_1^+ e_2^-)}{d\cos \Omega} = \int_0^{2\pi} \int_0^{m_\mu/2} \int_0^{m_\mu/2} [M^2 E_{e_1} E_{e_2} (m_\mu - E_{e_1^+} - E_{e_2}) dE_{e_1} dE_{e_2} d\phi_-]$$

$$= (0.0104) \frac{m_\mu^5}{128 \pi^4} \left[ \left| C_1 \right|^2 |c_{e_1^+}|^2 + \left| C_2 \right|^2 |d_{e_1^-}|^2 \right] - (\left| C_1 \right|^2 |c_{e_1^+}|^2 - \left| C_2 \right|^2 |d_{e_1^-}|^2)^2 \frac{P_\mu \cos \theta_+}{3}$$

$$+ |B_1|^2 + |B_2|^2 + \left| B_1 \right|^2 \left| c_{e_1^+} \right|^2 - \left| d_{e_1^-} \right|^2/3 - |B_2|^2 \left| d_{e_1^-} \right|^2/3 \left| c_{e_1^+} \right|^2/3 \left| d_{e_1^-} \right|^2$$

$$+ 16\left| G_2 \right|^2 \left| c_{e_1^+} \right|^2 + \left| G_1 \right|^2 \left| d_{e_1^-} \right|^2$$

$$\quad \times \text{Im} \left[ \frac{(2.6)B_1^2B_2 - 4G_1^2C_1 - 4G_2C_2^*] \sin \theta - P_\mu}{P_3 - P_4 P_\mu \cos \theta_-} \right] \quad (13)$$

The transverse polarizations are
where $d\Omega$ represents the differential solid angle of the momentum of $e_1^+$ relative to the spin of the muon.

From the above equation, we find that the longitudinal polarization of $e_1^+$ is

$$\langle s_{ T_1^+} \rangle = \frac{d\Gamma/d\Omega|_{e_1^+=1/\sqrt{3}} - d\Gamma/d\Omega|_{e_1^+=0}}{d\Gamma/d\Omega|_{e_1^+=0}} = \frac{P_3^+ + P_4^+ \mp \mu_p \cos \theta_+}{P_3^+ + P_4^+ \mp \mu_p \cos \theta_+}$$

where

$$P_3^+ = |C_1|^2 - |C_2|^2 + 16|G_2|^2 - 16|G_1|^2$$
$$P_4^+ = -|C_2|^2 - |C_1|^2 - 16|G_2|^2 - 16|G_1|^2 + 4|B_1|^2 + 4|B_2|^2$$
$$P_2^+ = |C_1|^2 + |C_2|^2 - 16|G_2|^2 + 2(16|G_2|^2 + |G_1|^2)$$
$$P_5^+ = |C_2|^2 - |C_1|^2 - 16|G_2|^2 + 16|G_1|^2 + 2|B_1|^2 - 2|B_2|^2.$$  \hspace{1cm}(17)

The transverse polarizations are

$$\langle s_{ T_2^+} \rangle = \frac{d\Gamma/d\Omega|_{e_1^+=1/\sqrt{3}} - d\Gamma/d\Omega|_{e_1^+=0}}{d\Gamma/d\Omega|_{e_1^+=0}} = \frac{\Re \left[ B_1 C_2^2 + B_2 C_1 + 24 G_1 B_1 - 24 G_2 B_2^2 \right] \sin \theta_+ \mu_p}{P_3^+ + P_4^+ \mp \mu_p \cos \theta_+}$$

and

$$\langle s_{ T_3^+} \rangle = \frac{d\Gamma/d\Omega|_{e_1^+=1/\sqrt{3}} - d\Gamma/d\Omega|_{e_1^+=0}}{d\Gamma/d\Omega|_{e_1^+=0}} = \frac{\Im \left[ B_1 C_2^2 + B_2 C_1 + 24 G_1 B_1 - 24 G_2 B_2^2 \right] \sin \theta_+ \mu_p}{P_3^+ + P_4^+ \mp \mu_p \cos \theta_+}.$$  \hspace{1cm}(19)

Like the case of the electron discussed in sect. [II A] the longitudinal polarization, $\langle s_{ T_1^+} \rangle$, does not give information on the CP-violating phases and can be used only as a cross-check for the derivation of the combinations listed in Eq. (7) by the methods discussed earlier. The ratio of $\langle s_{ T_2^+} \rangle$ and $\langle s_{ T_3^+} \rangle$ gives $\arg \left[ B_1 C_2^2 + B_2 C_1 + 24 G_1 B_1 - 24 G_2 B_2^2 \right]$. Considering that the absolute value of this combination is also unknown, $|\langle s_{ T_2^+} \rangle|^2 + |\langle s_{ T_3^+} \rangle|^2$ provides an independent piece of information. We have integrated over $\phi_-$ which means the measurement of the direction of the emitted electron is not necessary for this analysis.

### III. CONCLUSIONS AND PROSPECTS

A large variety of the beyond standard models predict a sizeable rate for $\mu^+ \rightarrow e^+ e^- e^+$ exceeding the present experimental bound. In principle, by studying the energy spectrum of the final particles and their angular distribution, it is possible to derive the form of the terms in the effective Lagrangian leading to this process and extract information on the absolute values of the couplings (see Eq. (7)). The effective Lagrangian responsible for $\mu^+ \rightarrow e^+ e^- e^+$ can include new CP-violating phases. In order to derive information on the CP-violating phases, we have suggested to measure the polarization of the emitted particles. In this letter, we have focused on the effective Lagrangian in Eq. (3) that can result from integrating out heavy scalar fields with LFV couplings at the tree level. The rest of the terms (i.e.,
A_L and A_R) are expected to be loop suppressed and are neglected in this analysis. We have shown that the transverse polarization of the emitted electron in μ^+ → e^+e^−e^+ is sensitive to arg[2.6B_1B_2^* − 4G_1^2C_2^* − 4G_2C_1^*] [see Eqs. (12,13)]. That is while the transverse polarizations of the emitted positron is given by arg[B_1C_2^* + B_2C_1^* + 24G_1^2B_1^* − 24G_2B_2^*]. From Eqs. (12,13,18,19), we observe that if the initial muon is unpolarized (i.e., P_μ = 0) the transverse polarizations of the emitted particles vanish. Thus, in order to derive the CP-violating phases, a source of polarized muons is required.

In sum, the effective Lagrangian in Eq. (3) includes six new couplings and five physical phases. By measuring the energy spectrum of the final particles and the angular distributions relative to the spin of the initial muon, one can derive the CP-conserving combinations listed in Eq. (4). i.e., four out of the six CP-conserving quantities. Neglecting the loop suppressed A_L and A_R couplings, the angular distribution cannot provide information on the phases. The transverse polarizations of the emitted particles provide four independent pieces of information on the phases and couplings. This information is not enough to reconstruct all the couplings but considerably reduces the degeneracy in the parameter space.

We have also discussed the longitudinal polarization of the emitted particles. The longitudinal polarizations do not depend on the phases of the effective couplings. It is noteworthy that even in the P_μ = 0 limit, the longitudinal polarizations of the positron, ⟨s_{τ−}⟩, and the electron, ⟨s_{e−}⟩, are nonzero and respectively yield information on the parity violating combinations |C_1|^2 − |C_2|^2 + 16|G_2|^2 − 16|G_1|^2 and |C_1|^2 − |C_2|^2 + 16|G_2|^2 − 16|G_1|^2 + 2(|B_2|^2 − |B_1|^2). Remember that in the P_μ = 0 limit, there is no preferred direction so the angular distribution of the final particles is uniform and does not yield information on the parity-violating combinations.

There are running and/or under construction experiments that aim to probing signals for μ → eγ [12] and μ → e conversion on nuclei [13] several orders of magnitudes below the present bounds on their rates. However, as shown in [4], it is possible that while μ^+ → e^+γe^+ is round the corner, the rates of μ → eγ and μ → e conversion are too low to be probed. In fact as shown in [4], the three experiments provide us with supplementary information on the parameters of the effective LFV Lagrangian. If the muons are produced from the decay of pions at rest (like the case of the running MEG experiment [12]), the initial muons in μ → eee will be polarized. On the other hand, there are well-established techniques to measure the polarization of the emitted particles in this energy range. In fact, such polarimetry has been used to measure the Michel parameters since 80’s [14]. As a result, if the rate of μ^+ → e^+γe^+ is close to the present bound and a hypothetical experiment finds statistically large number of such a process, performing the analysis proposed in this paper sounds possible.

In this letter, we have focused on the LFV three-body decay of the anti-muon, μ^− → e^+e^−e^+. The same discussion applies to the decay of the muon, μ^− → e^+e^−e^−. In this mode, the transverse polarizations of the electrons would give arg[B_1C_2^* + B_2C_1^* + 24G_1^2B_1^* − 24G_2B_2^*] and the transverse polarizations of the emitted positrons would give arg[2.6B_1B_2^* − 4G_1^2C_2^* − 4G_2C_1^*]. The method of measuring the polarization described in [14] is based on studying the distribution of the photon pair from the annihilation of the emitted positron on an electron in a target. If this method is to be employed, only the polarization of the positron can be measured. Thus, to derive both combinations, the experiment has to run in both muon and anti-muon modes.

The three-body LFV decay modes of the tau lepton such as τ → eee or τ → μμμ can also shed light on the underlying theory. Recently it has been shown that by studying the angular distribution of the final particles in τ → μμμ at the LHC, one can discriminate between various models [12]. Discussions in the present letter also apply to the decay modes τ → eee and τ → μμμ.

Appendix

In this appendix, we derive the decay rate of μ^+ → e^+_1e^-e^+_2. We first derive the decay rate into an electron of definite spin, summing over the spins of e^+_1 and e^+_2. We then concentrate on the spin of e^+_1 and derive the decay rate into a positron of definite spin, summing over the spins of the electron and the other positron.

With effective Lagrangian (3), we find

\[ M(μ^+ → e^+_1e^-e^+_2) = B_1μ \hat{1} + θ_5 e^+_1 \hat{1} e^- e^+_2 - B_1μ e^+_2 e^- e^+_1 + B_2μ \hat{1} - θ_5 e^+_1 \hat{1} e^- e^+_2 - B_2μ e^+_2 e^- e^+_1 + C_1μ \hat{1} + θ_5 e^+_1 \hat{1} e^- e^+_2 - C_1μ e^+_2 e^- e^+_1 + C_2μ \hat{1} - θ_5 e^+_1 \hat{1} e^- e^+_2 - C_2μ e^+_2 e^- e^+_1 - 4G_1μ e^{+}_1 e^{-} e^{+}_2 - 4G_2μ e^{+}_1 e^{-} e^{+}_2 - 24G_1^2μ e^{+}_1 e^{-} e^{+}_2. \]
Decay rate into $e^-$ with a given spin

Consider the decay $\mu^+ \rightarrow e^+_1 e^- e^+_2$ in the rest frame of the muon. Since we are interested in the spin of the electron, it is convenient to use the coordinate system defined as $\hat{T}_3^- \equiv \vec{P}_e^-/|\vec{P}_e^-|$, $\hat{T}_2^- \equiv (\hat{T}_3^- \times \vec{s}_\mu)/|\hat{T}_3^- \times \vec{s}_\mu|$ and $\hat{T}_1^- \equiv \hat{T}_2^- \times \hat{T}_3^-$. In this coordinate system,

\[
P_{\mu^+} = (m_\mu, 0, 0, 0) \quad P_{e_1^+} = E_{e_1^+}(1, \sin \alpha \cos \phi_+, \sin \alpha \sin \phi_+, \cos \phi_+,
\]

\[
P_{e^-} = (E_e, 0, 0, 0) \quad P_{e_2^+} = (m_\mu - E_{e_2^+} - E_e, -E_{e_2^+} \sin \alpha \cos \phi_+, -E_e - E_{e_2^+} \cos \phi_+)
\]

where the electron mass is neglected (see Fig. 3a). Writing the kinematics and neglecting effects of $O(m_e^2/m_\mu^2) \ll 1$, we find

\[
\cos \alpha = \frac{m_\mu^2 - 2m_\mu E_{e_2^+} - 2m_\mu E_e + 2E_{e_2^+}E_e}{2E_{e_2^+}E_e}.
\]

Summing over the spins of the emitted positrons, we find that

\[
(2\pi)^4 \int_0^{2\pi} (2E_{e_1^+})(2E_{e_2^+}) \sum_{\vec{s}_1^+, \vec{s}_2^+} |M|^2 d\phi_+ = \int_0^{2\pi} \int_{m_\mu/2}^{m_\mu/2} \int_{m_\mu/2 - E_e}^{m_\mu/2} \sum_{\vec{s}_1^+, \vec{s}_2^+} |M|^2 E_e E_{e_1^+}(m_\mu - E_e - E_{e_2^+})dE_{e_2^+}dE_e d\phi_+,
\]

where $d\Omega$ is the differential solid angle determining the orientation of the emitted electron. The factor $E_e E_{e_1^+}(m_\mu - E_e - E_{e_2^+})$ comes from the momentum-space volume for a three body decay [i.e., from $\delta^4(P_\mu - P_e - P_{e_1^+} - P_{e_2^+})d^3P_e d^3P_{e_1^+} d^3P_{e_2^+}$]. Inserting $|M|^2$ from Eq. (22), we obtain

\[
\sum_{\vec{s}_1^+, \vec{s}_2^+} \frac{d\Gamma(\mu^+ \rightarrow e_1^+ e^- e_2^+)}{d\Omega} = \frac{m_\mu^3}{8(2\pi)^4} \left[ \left( |c_e^-|^2 |B_1|^2 + |d_e^-|^2 |B_2|^2 \right) \int_0^{1/2} \int_{1/2 - y}^{1/2} \left(-1 + 3y + 4x - 2y^2 - 4x^2 - 4xy\right) dx dy \right.
\]

\[
+ \int_0^{1/2} \int_{1/2 - y}^{1/2} \left[ 1 - 2x - 2y + 2xy - \frac{2x + y - 1}{y} \right] (1 - 2x - 2y + 2xy + y^2) dx dy
\]

\[
+ \left. \left( \left( |C_1|^2 + 16 |G_2|^2 \right) |d_e^-|^2 (1 + \Im \mu \cos \theta_+) \right) \right] \int_0^{1/2} \int_{1/2 - y}^{1/2} y(1 - 2y) dx dy
\]

\[
- 8\Im \mu \Re \left( G_1 C_1^* d_e^- c_+ \right) \int_0^{1/2} \int_{1/2 - y}^{1/2} y(1 - 2y) dx dy
\]

\[
- 2\Im \mu \Re \left( B_1 B_2^* d_e^- c_+ \right) \sin \theta_+ \int_0^{1/2} \int_{1/2 - y}^{1/2} (2x + 2y - 1) \frac{2x - 1}{y} dx dy
\]

The integrals are all finite and lead to the numbers in Eq. (9).
Let us now concentrate on one of the positrons, $e_1^+$, whose momentum makes an angle of $\theta_+$ with $\vec{s}_\mu$ (see Fig. 1b). To perform this analysis, it is convenient to work in the following coordinate system: $\vec{T}_3^+ \equiv \vec{P}_{c_1^+} / |\vec{P}_{c_1^+}|$, $\vec{T}_2^+ \equiv \vec{T}_3^+ \times \vec{s}_\mu / |\vec{T}_3^+ \times \vec{s}_\mu|$ and $\vec{T}_1^+ \equiv \vec{T}_2^+ \times \vec{T}_3^+$. In the rest frame of the muon and in this coordinate system,

$$P_{c_1^+} = (m_\mu, 0, 0, 0) \quad P_{c_1^-} = E_e (1, \sin \alpha \cos \phi_-, \sin \alpha \sin \phi_-, \cos \alpha)$$

$$T_{c_1^+} = (E_{c_1^+, 0, 0, E_{c_1^-}}) \quad T_{c_1^-} = (m_{c_1^-} - E_{c_1^+} - E_e, -E_e \sin \alpha \cos \phi_-, -E_e \sin \alpha \sin \phi_-, -E_{c_1^+} - E_e \cos \alpha)$$

(25)

where $\alpha$ is given by Eq. (22).

Summing over the spins of $e_2^+$ and $e^-$, we find

$$(2\pi)^3 (2E_e) (2E_{c_1^+}) \int \sum_{\vec{s}_{\mu} \times \vec{s}_\mu} |M|^2 d\phi_- =$$

$$= \left( |B_1|^2 |c_{e_1^+}^2| + |B_2|^2 |d_{e_1^+}^2| \right) E_e \left( m_{c_1^-} - E_{c_1^+} (1 - \cos \alpha) \right)$$

$$+ 16 (|G_2|^2 |c_{e_1^+}^2| + |G_1|^2 |d_{e_1^+}^2|) E_e \left( m_{c_1^-} - E_{c_1^+} (1 - \cos \alpha) \right)$$

$$+ \left( |C_1|^2 |c_{e_1^+}^2| + |C_2|^2 |d_{e_1^+}^2| \right) E_e \left( m_{c_1^-} - E_{c_1^+} (1 - \cos \alpha) \right)$$

$$+ \sum_{\vec{s}_{\mu} \times \vec{s}_\mu} \left[ (|B_1|^2 |c_{e_1^+}^2| - |B_2|^2 |d_{e_1^+}^2|) E_e \cos \phi_- E^2 \sin \alpha (1 - \cos \alpha) \sin \theta_+ \right]$$

$$+ \Re \left[ B_1 C_1^* e_{c_1^-}^* d_{c_1^-} - B_2 C_2^* e_{c_1^-}^* d_{c_1^-} \right] E_e (m_{c_1^-} - E_{c_1^+} (1 - \cos \alpha)) (1 - \cos \alpha) \sin \theta_+$$

(26)

where $(c_{e_1^+}, d_{e_1^+})$ determines the spin of the emitted positron [see Eq. (14)]. The differential rate of the decay into a positron in a direction that makes an angle of $\theta_+$ with the spin of the initial muon is

$$\sum_{\vec{s}_{\mu} \times \vec{s}_\mu} \frac{d\Gamma (\mu^+ \rightarrow e_{c_1^+}^+ e_{c_1^-}^-)}{d\Omega} = \int_0^{2\pi} \int_0^{\pi/2} \sum_{\vec{s}_{\mu} \times \vec{s}_\mu} |M|^2 E_e E_{c_1^+} (m_{c_1^-} - E_{c_1^+}) dE_e dE_{c_1^-} d\phi_-$$

where $d\Omega$ is the differential solid angle determining the orientation of $e_1^+$. Inserting $|M|^2$ from Eq. (23), we obtain

$$\sum_{\vec{s}_{\mu} \times \vec{s}_\mu} \frac{d\Gamma (\mu^+ \rightarrow e_{c_1^+}^+ e_{c_1^-}^-)}{d\Omega} =$$

$$= \frac{m_5 \mu}{8 (2\pi)^2} \left[ \left( |d_{c_1^-}^2| B_1^2 + |c_{c_1^+}^2| B_2^2 \right) \int_0^{1/2} \int_0^{1/2} (1 - x - y)(2x + 2y - 1) dx dy \right.$$

$$+ \left( |c_{c_1^+}^2| B_1^2 + |d_{c_1^-}^2| B_2^2 \right) \int_0^{1/2} \int_0^{1/2} y(1 - 2y) dx dy$$

$$+ \left( |C_1|^2 |c_{e_1^-}^2| + |C_2|^2 |d_{c_1^-}^2| \right) \int_0^{1/2} \int_0^{1/2} x(1 - 2x) dx dy$$

$$+ 16 (|G_2|^2 |c_{e_1^-}^2| + |G_1|^2 |d_{c_1^-}^2|) \int_0^{1/2} \int_0^{1/2} x(1 - 2x) dx dy$$

$$+ \Re \left[ B_1 C_1^* e_{c_1^-}^* d_{c_1^-} - B_2 C_2^* e_{c_1^-}^* d_{c_1^-} \right] \int_0^{1/2} \int_0^{1/2} \left( 2x + 2y - 1 \right) \left( -\frac{2x - 2y + 2xy}{2y} \right) dx dy$$

$$+ \Re \left[ B_1 C_1^* e_{c_1^-}^* d_{c_1^-} - B_2 C_2^* e_{c_1^-}^* d_{c_1^-} \right] \int_0^{1/2} \int_0^{1/2} \left( 1 - 2x \right) \left( 2x - 2y + 2xy \right) \left( \frac{2x - 2y + 2xy}{2y} \right) dx dy$$
\[ + \ \mathbb{P}_\mu \cos \theta_+ (|B_1|^2 |c_{\epsilon_1}^e|^2 - |B_2|^2 |d_{\epsilon_1}^e|^2) \int_{1/2}^{1/2} \int_{1/2-y}^{1/2} y(1-2y) dx \, dy \\
+ 16\mathbb{P}_\mu \cos \theta_+ (|G_2|^2 |c_{\epsilon_1}^e|^2 - |G_1|^2 |d_{\epsilon_1}^e|^2) \int_{1/2}^{1/2} \int_{1/2-y}^{1/2} (1-2x) \frac{1-2x-2y+2xy}{2y} dx \, dy \\
+ 2\mathbb{P}_\mu (\text{Re}[B_1 C_2^* c_{\epsilon_1}^e d_{\epsilon_1}^e] + \text{Re}[B_2 C_1^* c_{\epsilon_1}^e d_{\epsilon_1}^e]) \sin \theta_+ \int_{1/2}^{1/2} \int_{1/2-y}^{1/2} (2xy + 0.5 - x - y) dx \, dy \\
+ 4\mathbb{P}_\mu (\text{Re}[G_1 B_1^* c_{\epsilon_1}^e d_{\epsilon_1}^e] - \text{Re}[G_2 B_2^* c_{\epsilon_1}^e d_{\epsilon_1}^e]) \sin \theta_+ \int_{1/2}^{1/2} \int_{1/2-y}^{1/2} \frac{(1-2x)(2x + 2y - 1)}{4x^2} dx \, dy. \] (27)
