Model-free Superhedging Duality

Matteo Burzoni, Marco Frittelli, Marco Maggis

May 3, 2016

Abstract

In a model free discrete time financial market, we prove the superhedging duality theorem, where trading is allowed with dynamic and semi-static strategies. We also show that the initial cost of the cheapest portfolio that dominates a contingent claim on every possible path \( \omega \in \Omega \), might be strictly greater than the upper bound of the no-arbitrage prices. We therefore characterize the subset of trajectories on which this duality gap disappears and prove that it is an analytic set.

Keywords: Superhedging Theorem, Model Independent Market, Model Uncertainty, Robust Duality, Finite Support Martingale Measure, Analytic Sets.

1 Introduction

The aim of this article is the proof of the following discrete time, model-independent version of the superhedging theorem.

**Theorem 1.1** (Superhedging). Let \( g : \Omega \to \mathbb{R} \) be an \( \mathcal{F} \)-measurable random variable. Then

\[
\inf \{ x \in \mathbb{R} \mid \exists H \in \mathcal{H} \text{ such that } x + (H \cdot S)_T \geq g \text{ } \mathcal{M}-q.s. \} \\
= \inf \{ x \in \mathbb{R} \mid \exists H \in \mathcal{H} \text{ such that } x + (H \cdot S)_T(\omega) \geq g(\omega) \quad \forall \omega \in \Omega \} \\
= \sup_{Q \in \mathcal{M}} E_Q[g] = \sup_{Q \in \mathcal{M}} E_Q[g],
\]

where

\[
\Omega_* := \{ \omega \in \Omega \mid \exists Q \in \mathcal{M} \text{ s.t. } Q(\omega) > 0 \}. \tag{1}
\]

We adopt the following setting and notations: let \( \Omega \) be a Polish space and \( \mathcal{F} = \mathcal{B}(\Omega) \) be the Borel sigma-algebra; \( T \in \mathbb{N} \), \( I := \{0, ..., T\} \), \( S = (S_t)_{t \in I} \) be an \( \mathbb{R}^d \)-valued stochastic process on \((\Omega, \mathcal{F})\) representing the price process of \( d \in \mathbb{N} \) assets; \( \mathcal{P} \) be the set of all probability measures on \((\Omega, \mathcal{F})\); \( \mathcal{F}^S := \{ \mathcal{F}_t^S \}_{t \in I} \) be the natural filtration and \( \mathcal{F} := \{ \mathcal{F}_t \}_{t \in I} \) be the Universal Filtration, namely

\[
\mathcal{F}_t := \bigcap_{P \in \mathcal{P}} \mathcal{F}_t^S \vee \mathcal{N}_t^P, \text{ where } \mathcal{N}_t^P = \{ N \subseteq A \in \mathcal{F}_t^S \mid P(A) = 0 \};
\]

*email: matteo.burzoni@unimi.it, marco.frittelli@unimi.it, marco.maggis@unimi.it
be the class of $\mathbb{F}$-predictable stochastic processes, with values in $\mathbb{R}^d$, representing the family of admissible trading strategies; $(H \cdot S)_T := \sum_{t=1}^T \sum_{j=1}^d H_j^t (S_j^t - S_j^{t-1}) = \sum_{t=1}^T H_t \cdot \Delta S_t$ be the gain up to time $T$ from investing in $S$ adopting the strategy $H$. We denote

$$\mathcal{M} := \{Q \in \mathcal{P} \mid S \text{ is an } \mathbb{F}\text{-martingale under } Q\},$$

$$\mathcal{P}_f := \{Q \in \mathcal{P} \mid \text{supp}(Q) \text{ is finite}\},$$

$$\mathcal{M}_f := \mathcal{M} \cap \mathcal{P}_f,$$

where the support of $P \in \mathcal{P}$ is defined by $\text{supp}(P) = \bigcap \{C \in \mathcal{F} \mid C \text{ closed, } P(C) = 1\}$. The family of $\mathcal{M}$-polar sets is given by $\mathcal{N} := \{N \subseteq A \in \mathcal{F} \mid Q(A) = 0 \ \forall Q \in \mathcal{M}\}$ and a property is said to hold quasi surely (q.s.) if it holds outside a polar set. We adopt the convention $\infty - \infty = -\infty$ for those random variables $g$ whose positive and negative part is not integrable. We are also assuming the existence of a numeraire asset $S^0_t = 1$ for all $t \in I$.

**Probability free set up.** In the statement of the superhedging theorem there is no reference to any a priori assigned probability measure and the notions of $\mathcal{M}$, $\mathcal{H}$ and $\Omega_*$ only depend on the measurable space $(\Omega, \mathcal{F})$ and the price process $S$. In general the class $\mathcal{M}$ is not dominated.

We are not imposing any restriction on $S$ so that it may describe generic financial securities (for examples, stocks and/or options). However, in the framework of Theorem 1.1 the class $\mathcal{H}$ of admissible trading strategies requires dynamic trading in all assets. In Theorem 1.2 below we extend this setup to the case of semi-static trading on a finite number of options.

As illustrated in Section 4 we explicitly show that the initial cost of the cheapest portfolio that dominates a contingent claim $g$ on every possible path

$$\inf \{x \in \mathbb{R} \mid \exists H \in \mathcal{H} \text{ such that } x + (H \cdot S)_T(\omega) \geq g(\omega) \ \forall \omega \in \Omega\}$$

(2)

can be strictly greater than $\sup_{Q \in \mathcal{M}} E_Q[g]$, unless some artificial assumptions are imposed on $g$ or on the market. In order to avoid these restrictions on the class of derivatives, it is crucial to select the correct set of paths (i.e. $\Omega_*$) where the superhedging strategy can be efficiently employed.

**On the set $\Omega_*$.** In Theorem 1.1 the pathwise model independent inequality in (2), is replaced with an inequality involving only those $\omega \in \Omega$ which are weighted by at least one martingale measure $Q \in \mathcal{M}$. In [BFM16] (see also Proposition 3.1) it is shown the existence of the maximal $\mathcal{M}$-polar set $N_*$, namely a set $N_* \in \mathcal{N}$ containing any other set $N \in \mathcal{N}$. Moreover

$$\Omega_* = (N_*)^C.$$

(3)

The inequality $x + (H \cdot S)_T \geq g$ $\mathcal{M}$-q.s. holds by definition outside any $\mathcal{M}$-polar set and therefore it is equivalent, thanks to (3), to the inequality $x + (H \cdot S)_T(\omega) \geq g(\omega) \ \forall \omega \in \Omega_*$, which justifies the first equality in Theorem 1.1. The set $\Omega_*$ can be equivalently determined (see Proposition 3.1) via the set $\mathcal{M}_f$ of martingale measures with finite support, a property that turns out to be crucial in several proofs.

We stress that we do not make any ad hoc assumptions on the discrete time financial model and notice that $\Omega_*$ is determined only by $S$: indeed the set $\mathcal{M}$ can be written also as $\mathcal{M} = \mathcal{M}_f$. 

\{ Q \in \mathcal{P} \mid S \text{ is an } F^S\text{-martingale under } Q \}.  One of the main technical result of the paper is the proof that the set $\Omega_*$ is an analytic set (Proposition 5.5) and so our findings show that the natural setup for studying this problem is $(\Omega, S, F, \mathcal{H})$ with $F$ the Universal filtration (which contains the analytic sets) and $\mathcal{H}$ the class of $F$-predictable processes. We also point out that we could replace any sigma-algebra $F_t$ with the sub sigma-algebra generated by the analytic sets of $F_t^S$.

On Model Independent Arbitrage and the condition $\mathcal{M} \neq \emptyset$. In case $\mathcal{M} = \emptyset$ then $\Omega_* = \emptyset$ and the theorem is trivial, as each term in the equalities of Theorem 1.1 is equal to $-\infty$, provided we convene that any $\mathcal{M}$-q.s. inequalities hold true when $\mathcal{M} = \emptyset$.

For this reason we will assume without loss of generality $\mathcal{M} \neq \emptyset$, and recall that this condition can be reformulated in terms of absence of Model Independent Arbitrages. A Model Independent $\mathcal{H}$-Arbitrage consists in a trading strategy $H \in \mathcal{H}$ such that $(H \cdot S)_T(\omega) > 0$ $\forall \omega \in \Omega$. However, as shown in [BFM16] No Model Independent $\mathcal{H}$-Arbitrage is not sufficient to guarantees $\mathcal{M} \neq \emptyset$. Indeed we need the stronger condition of No Model Independent $\mathcal{H}$-Arbitrage to hold, where $\mathcal{H}$ is a wider class of $\bar{F}$-predictable stochastic processes for a suitable enlarged filtration $\bar{F}$. Hence the non trivial statement in Theorem 1.1 (i.e. when $\mathcal{M} \neq \emptyset$) regards the superhedging duality under No Model Independent $\mathcal{H}$-Arbitrage.

1.1 Superhedging with semi-static strategies on options and stocks.

We now allow for the possibility of static trading in a finite number of options. Let us add to the previous market $k$ options $\Phi = (\phi^1, ..., \phi^k)$ which expires at time $T$ and assume without loss of generality that they have zero initial cost. We assume that each $\phi^j$ is an $F$-measurable random variable. Define $h\Phi := \sum_{j=1}^k h^j \phi^j$, $h \in \mathbb{R}^k$, and

$$\mathcal{M}_\Phi := \{ Q \in \mathcal{M}_f \mid E_Q[\phi^j] = 0 \forall j = 1, ..., k \} = \{ Q \in \mathcal{M}_f \mid E_Q[h\Phi] = 0 \forall h \in \mathbb{R}^k \}, \quad (4)$$

which are the options-adjusted martingale measures, and

$$\Omega_\Phi := \{ \omega \in \Omega \mid \exists Q \in \mathcal{M}_\Phi \text{ s.t. } Q(\omega) > 0 \} \subseteq \Omega_*.. \quad (5)$$

We have by definition that for every $Q \in \mathcal{M}_\Phi$ the support satisfies $\text{supp}(Q) \subseteq \Omega_\Phi$. We define the superhedging price when semi-static strategies are allowed by

$$\pi_{\Phi}(g) := \inf \{ x \in \mathbb{R} \mid \exists (H, h) \in \mathcal{H} \times \mathbb{R}^k \text{ such that } x + (H \cdot S)_T(\omega) + h\Phi(\omega) \geq g(\omega) \forall \omega \in \Omega_\Phi \}. \quad (6)$$

With the same methodology used in the proof of Theorem 1.1 we will obtain in Section 6.3 the superhedging duality with semi-static strategies, under the assumption $\mathcal{M}_\Phi = \{ Q \in \mathcal{M}_f \mid \text{supp}(Q) \subseteq \Omega_\Phi \}$.\footnote{We wish to thank J. Obloj and Z. Hou for pointing out that this hypothesis is necessary for the argument used in the proof of Theorem 1.2. We will show in a forthcoming paper (joint with J. Obloj and Z. Hou) that the result holds in full generality dropping this hypothesis.}

**Theorem 1.2** (Super-hedging with options). Let $g : \Omega \mapsto \mathbb{R}$ and $\phi^j : \Omega \mapsto \mathbb{R}$, $j = 1, ..., k$, be $F$-measurable random variables. Then

$$\pi_{\Phi}(g) = \sup_{Q \in \mathcal{M}_\Phi} E_Q[g].$$
1.2 Comparison with the related literature.

In the classical case when a reference probability is fixed, this subject was originally studied by El Karoui and Quenez [KQ95]; see also [Ka97] and [DS94] and the references cited therein.

In [BN15] a superhedging theorem is proven in the case of a non-dominated class of priors $\mathcal{P}' \subseteq \mathcal{P}$. The result strongly relies on two technical hypothesis: (i) The state space $\Omega$ has a product structure, $\Omega = \Omega_1^{T}$, where $\Omega_1$ is a certain fixed Polish space and $\Omega_t^1$ is the $t$-fold product space; (ii) The set of priors $\mathcal{P}'$ is also obtained as a collection of product measures $P := P_1 \otimes \ldots \otimes P_T$ where every $P_t$ is a measurable selector of a certain random class $\mathcal{P}_t' \subseteq \mathcal{P}(\Omega_1)$. $\mathcal{P}_t'(\omega)$ represents the set of possible models for the $t$-th period, given state $\omega$ at time $t$. An essential requirement on $\mathcal{P}_t'$ is that the graph($\mathcal{P}_t'$) must be an analytic subset of $\Omega_1^{T} \times \mathcal{P}(\Omega_1)$. These assumptions are crucial in order to apply the measurable selection and stochastic control arguments which lead to the proof of the superhedging theorem. In our setting we do not impose restrictions on the state space $\Omega$ so the result cannot be deduced from [BN15] for $\mathcal{P}' = \mathcal{M}$. Moreover, even in the case of $\Omega = \Omega_1^{T}$, the class of martingale probability measures $\mathcal{M}$ is endogenously determined by the market and we do not require that it satisfies any additional restrictions. Furthermore, the techniques employed to deduce our version of the superhedging duality theorem are completely different, as they rely on the results of [BFM16]. Note that in the particular simple case of $\Omega := (\mathbb{R}^d)^{T}$ with $S$ the canonical process, from [BFM16], we have that $\Omega_* = \Omega$ and there are no $\mathcal{M}$-polar sets. We thus have the equivalence between $\mathcal{P}$-q.s. and $\mathcal{M}$-q.s. equalities. The superhedging Theorem of [BN15] can be therefore applied with $\mathcal{P}' = \mathcal{P}$ and the two results coincide.

The relevance of the superhedging problem without any a priori specified set of probability measures is revealed by the increasing amount of literature on this topic. The problem has been studied as a particular case of a Skorokhod Embedding Problem (see [BHR01, CO11, Ho11]), following the pioneering work [Ho98] on robust hedging. The reformulation of the superhedging duality in the framework of optimal mass transport led to important results both in discrete and continuous time as in [BHL13, DS13, DS15, GHLT14, HL0ST16, OH15, TT13].

Different approaches are taken in [AB16, Ri15]. In [Ri15] the continuity assumptions on the assets allow to embed the problem in the linear programming framework and to obtain the desired equality in a one period market. In [AB16] from a model independent version of the Fundamental Theorem of Asset Pricing they deduce the following superhedging duality (Theorem 1.4 [AB16]):

$$
\inf \{ x \in \mathbb{R} | \exists (H, h) \in \mathcal{H} \times \mathbb{R}^k \text{ s.t. } x + (H \cdot S)_T(\omega) + h(\Phi(\omega)) \geq g(\omega) \ \forall \omega \in \Omega \} = \sup_{Q \in \mathcal{M}_0} E_Q[g].
$$

(7)

They assume a discrete time market, with one dimensional canonical process $S$ on the path space $\Omega = [0, \infty)^T$ and an arbitrary (but non empty) set of options on $S$ available for static trading. Theorem 1.4 in [AB16] relies on two additional technical assumptions: (i) The existence of an option with super-linearly growing and convex payoff; (ii) The upper semi-continuity of the claim $g$.

The example in Section [4] shows that without the upper semi-continuity of the claim $g$ the duality in (7) fails and it also points out that the reason for this is the insistence of superhedging over the whole space $\Omega$, instead of over the relevant set of paths $\Omega_*$. Our result holds for a $d$-
dimensional (not necessarily canonical) process \( S \) and does not necessitate the existence of any options.

2 Aggregation results

In this section we investigate when certain conditions (like superhedging or hedging) which hold \( Q \)-a.s. for all \( Q \in \mathcal{M} \), ensure the validity of the correspondent pathwise conditions on \( \Omega^* \).

For an arbitrary sigma-algebra \( \mathcal{G} \) and for \( \mathcal{G} \)-measurable random variables \( X \) and \( Y \), we write \( X > Y \) if \( X(\omega) > Y(\omega) \) for all \( \omega \in \Omega \). When we specify \( X > Y \) on a measurable set \( A \subset \Omega \) it means that \( X(\omega) > Y(\omega) \) holds for all \( \omega \in A \). Similarly for \( X \geq Y \) and \( X = Y \).

We recall that absence of classical arbitrage opportunities, with respect to a probability \( P \in \mathcal{P} \), is denoted by \( NA(P) \). We set

\[
\mathcal{L}(\Omega, \mathcal{G}) := \{ f : \Omega \to \mathbb{R} \mid \text{\( \mathcal{G} \)-measurable} \},
\]

\[
\mathcal{L}(\Omega, \mathcal{G})_+ := \{ f \in \mathcal{L}(\Omega, \mathcal{G}) \mid f \geq 0 \}.
\]

The linear space of attainable random payoffs with zero initial cost is given by

\[
\mathcal{K} := \{ (H \cdot S)_T \in \mathcal{L}(\Omega, \mathcal{F}) \mid H \in \mathcal{H} \}.
\]

Recall that the set of events supporting martingale measures \( \Omega^* \) is defined in (1) and observe that the convex cones

\[
\mathcal{C} := \{ f \in \mathcal{L}(\Omega, \mathcal{F}) \mid f \leq k \text{ on } \Omega^* \text{ for some } k \in \mathcal{K} \},
\]

\[
\mathcal{C}(Q) := \{ f \in \mathcal{L}(\Omega, \mathcal{F}) \mid f \leq k \text{ \( Q \)-a.s. for some } k \in \mathcal{K} \}.
\]

are related by \( \mathcal{C} \subseteq \mathcal{C}(Q) \), if \( Q \in \mathcal{M} \).

The main Theorem \( \ref{theo:main} \) relies on the following cornerstone proposition that will be proved in Section 5, as its proof requires several technical arguments.

**Proposition 2.1.** Let \( g \in \mathcal{L}(\Omega, \mathcal{F}) \) and define

\[
\pi^*(g) := \inf \{ x \in \mathbb{R} \mid \exists H \in \mathcal{H} \text{ s.t. } x + (H \cdot S)_T \geq g \text{ on } \Omega^* \} \quad (10)
\]

\[
\pi_Q(g) := \inf \{ x \in \mathbb{R} \mid \exists H \in \mathcal{H} \text{ s.t. } x + (H \cdot S)_T \geq g \text{ \( Q \) a.s. } \} \quad (11)
\]

Then

\[
\pi^*(g) = \sup_{Q \in \mathcal{M}_f} \pi_Q(g) \quad (12)
\]

\[
\mathcal{C} = \bigcap_{Q \in \mathcal{M}_f} \mathcal{C}(Q). \quad (13)
\]

In particular, if \( \pi^*(g) < +\infty \) the infimum is a minimum.

**Corollary 2.2.** Let \( g \in \mathcal{L}(\Omega, \mathcal{F}) \) and \( x \in \mathbb{R} \). If for every \( Q \in \mathcal{M}_f \) there exists \( H^Q \in \mathcal{H} \) such that \( x + (H^Q \cdot S)_T \geq g \text{ \( Q \)-a.s.} \) then there exists \( H \in \mathcal{H} \) such that \( x + (H \cdot S)_T(\omega) \geq g(\omega) \) for every \( \omega \in \Omega^* \).
Proof. By assumption, $g - x \in C(Q)$ for every $Q \in \mathcal{M}_f$. From $C = \bigcap_{Q \in \mathcal{M}_f} C(Q)$ we obtain $g - x \in C$.

**Corollary 2.3** (Perfect hedge). Let $g \in L(\Omega, \mathcal{F})$. If for every $Q \in \mathcal{M}_f$ there exists $H^Q \in \mathcal{H}$, $x^Q \in \mathbb{R}$ such that $x^Q + (H^Q \cdot S)_T = g$ $Q$-a.s. then there exists $H \in \mathcal{H}, x \in \mathbb{R}$ such that $x + (H \cdot S)_T(\omega) = g(\omega)$ for every $\omega \in \Omega_s$, and $x^Q = x$ for every $Q \in \mathcal{M}_f$.

**Proof.** Note first that, from the hypothesis, for every $Q \in \mathcal{M}_f$ there exists $H^Q \in \mathcal{H}$, $x^Q \in \mathbb{R}$ such that $x^Q + (H^Q \cdot S)_T(\omega) = g(\omega)$ for every $\omega \in \text{supp}(Q)$. We first show that $x^Q$ does not depend on $Q$. Assume there exist $Q_1, Q_2 \in \mathcal{M}_f$ such that $x^Q_1 < x^Q_2$. For every $\lambda \in (0, 1)$ set $Q_\lambda := \lambda Q_1 + (1 - \lambda)Q_2 \in \mathcal{M}_f$. Then there exist $H^\lambda \in \mathcal{H}$ and $x^\lambda \in \mathbb{R}$ such that $x^{Q_1} + (H^\lambda \cdot S)_T(\omega) = g(\omega)$ for every $\omega \in \text{supp}(Q_\lambda) = \text{supp}(Q_1) \cup \text{supp}(Q_2)$. Therefore $x^{Q_1} + (H^\lambda \cdot S)_T(\omega) = g(\omega)$ for every $\omega \in \text{supp}(Q_i)$, for any $i = 1, 2$, and from $NA(Q_i)$ we necessarily have that $x^{Q_1} = x^\lambda$. Since $x + (H^\lambda \cdot S)_T(\omega) = g(\omega)$ for every $\omega \in \text{supp}(Q)$ we can apply Corollary 2.2 which implies the existence of $H \in \mathcal{H}$ such that $x + (H \cdot S)_T(\omega) \geq g(\omega)$ on $\Omega_s$. Moreover $x - x + (H \cdot S)_T(\omega) \geq g(\omega) - g(\omega)$ for every $\omega \in \text{supp}(Q)$ implies $(H \cdot S)_T(\omega) \geq 0$ for every $\omega \in \text{supp}(Q)$. Since $NA(Q)$ holds, we conclude $(H \cdot S)_T(\omega) = 0$ for every $\omega \in \text{supp}(Q)$. Thus for every $Q \in \mathcal{M}_f$ we have $x + (H \cdot S)_T(\omega) = g(\omega)$ on $\text{supp}(Q)$ and hence the thesis follows from Proposition 4.18 [BFM16] (or Proposition 3.1).

**Corollary 2.4** (Bipolar representation). Let $C$ be defined in (8). Then

$$C = \{g \in L(\Omega, \mathcal{F}) \mid E_Q[g] \leq 0 \forall Q \in \mathcal{M}_f\} \quad (14)$$

**Proof.** Clearly $C \subseteq \{g \in L(\Omega, \mathcal{F}) \mid E_R[g] \leq 0 \forall R \in \mathcal{M}_f\} =: \overline{C}$. Fix $Q \in \mathcal{M}_f$ and observe that $L^0(\Omega, \mathcal{F}, Q) \equiv L^1(\Omega, \mathcal{F}, Q) \equiv L^\infty(\Omega, \mathcal{F}, Q)$, which denote, respectively, the space of equivalent classes of $Q$-almost everywhere integrable and $Q$-a.s. bounded $\mathcal{F}$-measurable random variables on $\Omega$. For $g \in L(\Omega, \mathcal{F})$ we denote with the capital letter $G$ the corresponding equivalence class $G \in L^0(\Omega, \mathcal{F}, Q)$. Denote also by $L^0_G(\Omega, \mathcal{F}, Q)$ the $Q$-a.s. non negative elements of $L^0(\Omega, \mathcal{F}, Q)$. The quotient of $K$ and $C(Q)$ with respect to the $Q$-a.s. identification $\sim_Q$ are denoted respectively by

$$K_Q := \{K \in L^0(\Omega, \mathcal{F}, Q) \mid K = (H \cdot S)_T \quad Q-a.s., \quad H \in \mathcal{H}\},$$

$$C_Q := \{G \in L^0(\Omega, \mathcal{F}, Q) \mid \exists K \in K_Q \text{ such that } G \leq K \quad Q-a.s.\} = K_Q - L^0_+(\Omega, \mathcal{F}, Q).$$

Now we may follow the classical arguments: the convex cone $C_Q$ is closed in probability with respect to $Q$ (see e.g. [KS01] Theorem 1). As $Q \in \mathcal{M}_f, C_Q$ is also closed in $L^1(\Omega, \mathcal{F}, Q)$ and therefore:

$$(C_Q)_0^0 = \{Z \in L^\infty(\Omega, \mathcal{F}, Q) \mid E[ZG] \leq 0 \forall G \in C_Q\} \subseteq L^\infty(\Omega, \mathcal{F}, Q) \cap L^0_+(\Omega, \mathcal{F}, Q).$$

Notice that $R \ll Q$ and $R \in \mathcal{M}_f$ if and only if $R \ll Q$ and $\frac{dR}{dQ} \in (C_Q)_0^0$. Hence:

$$(C_Q)_0^0 = \{G \in L^1(\Omega, \mathcal{F}, Q) \mid E[ZG] \leq 0 \forall Z \in C(Q)_0^0\}$$

$$= \left\{G \in L^1(\Omega, \mathcal{F}, Q) \mid E[R|G] \leq 0 \forall R \ll Q \text{ s.t. } \frac{dR}{dQ} \in (C_Q)_0^0\right\}$$

$$= \{G \in L^1(\Omega, \mathcal{F}, Q) \mid E[R|G] \leq 0 \forall R \ll Q \text{ s.t. } R \in \mathcal{M}_f\} \quad (15)$$
Let $g \in \mathcal{C}$. By the characterization in [15] the corresponding $G$ belongs to $(\mathcal{C}Q)^{00}$. By the bipolar theorem $CQ = (\mathcal{C}Q)^{00}$ and therefore $G \in CQ$ and $g \in \mathcal{C}(Q)$ (as defined in [9]). Since this holds for any $Q \in \mathcal{M}_f$, from $\mathcal{C} = \bigcap_{Q \in \mathcal{M}_f} \mathcal{C}(Q)$ (Proposition 2.1) we conclude that $g \in \mathcal{C}$.

**Remark 2.5.** One may ask whether the bipolar duality (14) implies that $\mathcal{C}$ is closed with respect to some topology. To answer this question let us introduce on $\mathcal{L}(\Omega, F)$ the following equivalence relation: for any $X, Y \in \mathcal{L}(\Omega, F)$

$$X \sim Y \text{ if and only if } X(\omega) - Y(\omega) = k(\omega) \text{ for some } k \in \mathcal{K} \text{ and for every } \omega \in \Omega_*.$$ 

Consider the quotient space $\mathcal{L}(\Omega, F) = \mathcal{L}(\Omega, F)/\sim$, denote with $[X]$ the equivalent class in $\mathcal{L}(\Omega, F)$ having $X$ as a representative and let $V_f$ be the vector space generated by $\mathcal{M}_f$. We first claim that the couple $(\mathcal{L}(\Omega, F), V_f)$ is a separated dual pair under the bilinear form $\langle \cdot, \cdot \rangle : \mathcal{L}(\Omega, F) \times V_f \to \mathbb{R}$ defined by: $\langle [X], \mu \rangle \mapsto E[\mu][X]$, for any $X \in [X]$. Notice that the form $\langle [X], \mu \rangle \mapsto E[\mu][X]$ is well posed as $E[\mu][k] = 0$ for all $k \in \mathcal{K}$ and the pairing is obviously bilinear. Clearly if $\mu \neq 0$ then there exists $\omega \in \Omega_*$ such that $\mu(\omega) \neq 0$ and $E[\mu][1_\omega] \neq 0$. Thus we have showed that $\langle [X], \mu \rangle = 0$, for every $[X]$, implies $\mu = 0$.

We now prove that $\langle [X], \mu \rangle = 0$ for every $\mu$ implies $[X] = [0]$. By contradiction assume $[X] \neq [0]$. By assumption, $X$ can not be replicable at a non zero cost. Observe that if $X \in [X]$ is replicable at zero cost in any market $(\Omega, F, S; Q)$ for any possible choice $Q \in \mathcal{M}_f$ then by Corollary 2.3 $X$ is pathwise replicable for every $\omega \in \Omega_*$, or in other words: $[X] = [0]$.

Hence our assumption $[X] \neq [0]$ implies that there exists a $Q \in \mathcal{M}_f$ such that the market $(\Omega, F, S; Q)$ is not complete, so that $\mathcal{M}_c(Q) := \{Q^* \sim Q \mid Q^* \in \mathcal{M}\} \neq \{Q\}$, and $X \in [X]$ is not replicable in such market. Then

$$\inf_{Q^* \in \mathcal{M}_c(Q)} E_{Q^*}[X] < \sup_{Q^* \in \mathcal{M}_c(Q)} E_{Q^*}[X].$$

As $Q \in \mathcal{M}_f$ has finite support, $\mathcal{M}_c(Q) \subset \mathcal{M}_f$ and there exists a $\mu \in \mathcal{M}_c(Q) \subset V_f$ such that $E[\mu][X] \neq 0$, which is a contradiction.

Now we conclude that the cone $\mathcal{C}/\sim$ is closed with respect to the weak topology $\sigma(\mathcal{L}(\Omega, F), V_f)$.

Indeed, from (14) we obtain that

$$\mathcal{C}/\sim = \{[g] \in \mathcal{L}(\Omega, F) \mid E_Q[g] \leq 0 \text{ for all } Q \in \mathcal{M}_f\} = \bigcap_{Q \in \mathcal{M}_f} \{g \in \mathcal{L}(\Omega, F) \mid E_Q[g] \leq 0\}$$

is the intersection of $\sigma(\mathcal{L}(\Omega, F), V_f)$-closed sets.

### 3 Proof of Theorem 1.1

We first recall from [BFM16] the relevant properties of the set $\Omega_*$ that will be needed several times in the proofs.

**Proposition 3.1 (Proposition 4.18, [BFM16]).** In the setting described in Section 4 we have

$$\mathcal{M} \neq \emptyset \iff \Omega_* \neq \emptyset \iff \mathcal{M}_f \neq \emptyset$$

$$\Omega_* = \left\{ \omega \in \Omega \mid \exists Q \in \mathcal{M}_f \text{ s.t. } Q(\omega) > 0 \right\}. \quad (16)$$

The complement of $\Omega_*$ is the maximal $\mathcal{M}$-polar set.
Proof of Theorem 1.1  As already stated in the introduction, we may assume w.l.o.g. that \( M \neq \emptyset \), or equivalently \( M_f \neq \emptyset \). The first equality of the theorem holds because of the definition of \( M \)-q.s. inequality and the fact that \( \Omega_* \) is the maximal \( M \)-polar set.

Step 1: Here we show that
\[
\inf \{ x \in \mathbb{R} \mid \exists H \in \mathcal{H} \text{ such that } x + (H \cdot S)_{T}(\omega) \geq g(\omega) \, \forall \omega \in \Omega_* \} = \sup_{Q \in M_f} E_Q[g].
\]
Note first that the left hand side of the previous equation can be rewritten as \( \inf \{ x \in \mathbb{R} \mid g - x \in \mathcal{C} \} \).

From Corollary 2.4 it follows:
\[
\begin{align*}
\inf \{ x \in \mathbb{R} \mid g - x \in \mathcal{C} \} &= \inf \{ x \in \mathbb{R} \mid E_Q[g - x] \leq 0 \, \forall Q \in M_f \} \\
&= \inf \{ x \in \mathbb{R} \mid x \geq E_Q[g] \, \forall Q \in M_f \} \\
&= \sup \{ E_Q[g] \mid Q \in M_f \}.
\end{align*}
\]

Step 2: We end the proof by showing that for any \( g \in \mathcal{L}(\Omega, \mathcal{F}) \)
\[
\sup_{Q \in M} E_Q[g] = \sup_{Q \in M_f} E_Q[g],
\]
where we adopt the convention \( \infty - \infty = -\infty \) for those random variables \( g \) whose positive and negative part is not integrable. Set:
\[
m := \sup_{Q \in M} E_Q[g], \quad l := \sup_{Q \in M_f} E_Q[g].
\]
We obviously have that \( l \leq m \) so that we only have to prove the converse inequality. If \( l = \infty \) there is nothing to prove. Suppose then \( l < \infty \). We first show that
\[
\text{if } Q \in M \text{ satisfy } E_Q[g] > l \Rightarrow E_Q[g] = \infty
\]
Suppose indeed by contradiction that there exists \( Q \in M \setminus M_f \) such that \( l < E_Q[g] < \infty \). Consider now an arbitrary version of the process \( g_t := E_Q[g \mid F_t] \) and extend the original market with the asset \( S_t^{d+1} := g_t \) for \( t \in I \). We obviously have that \( Q \) is a martingale measure for the extended market and from Proposition 3.1 this implies the existence of a \( g \)-martingale measure \( Q_f \) which, by construction, belongs to \( M_f \). Since \( E_{Q_f}[g] = g_0 > l \), which is the supremum of the expectations of \( g \) over \( M_f \), we have a contradiction.

From (18) we readily infer that if \( m < \infty \) then \( l = m \). We are only left to study the case of \( m = \infty \) and we show that this is not possible under the hypothesis \( l < \infty \). Consider first the class of martingale measures \( Q(g) \subset M \) such that \( E_Q[g^-] = \infty \). We obviously have that \( Q(g) \cap M_f = \emptyset \), moreover, since \( l < m = \infty \) from (18) and from \( \infty - \infty = -\infty \), there exists \( \tilde{Q} \in M \setminus Q(g) \) such that \( E_{\tilde{Q}}[g] = \infty \) and \( E_{\tilde{Q}}[g^-] < \infty \). Consider now the sequence of claims \( g_n := g \wedge n \) for any \( n \in \mathbb{N} \).

From \( E_{\tilde{Q}}[g^-] < \infty \) and Monotone Convergence Theorem we have \( E_{\tilde{Q}}[g \wedge n] \uparrow E_{\tilde{Q}}[g] = \infty \), hence, there exists \( \pi \in \mathbb{N} \) such that \( \pi \geq E_{\tilde{Q}}[g \wedge \pi] > l \). Note now that
\[
\sup_{Q \in M_f} E_Q[g \wedge \pi] \leq \sup_{Q \in M_f} E_Q[g] = l < E_{\tilde{Q}}[g \wedge \pi]
\]
Applying (18) to \( g \wedge \pi \) we get \( E_{\tilde{Q}}[g \wedge \pi] = +\infty \), which is a contradiction since the contingent claim \( g \wedge \pi \) is bounded.
4 Example: forget about superhedging everywhere!

Let \((\Omega, \mathcal{F}) = (\mathbb{R}^+, \mathcal{B}(\mathbb{R}^+))\). Consider a one period market \((T = 1)\) defined by a non-risky asset \(S^0_t \equiv 1\) for \(t = 0, 1\) (interest rate is zero) and a single risky asset \(S^1_T(\omega) = \omega\) with initial price \(S^1_0 := s_0 > 0\). In this market we also have two options \(\Phi = (\phi^0, \phi^1)\), where \(\phi^0 := f^0(S_T)\) is a butterfly spread option and \(\phi^1 := f^1(S_T)\) is a power option, i.e.

\[
\begin{align*}
   f^0(x) &= (x - K_0)^+ - 2(x - (K_0 + 1))^+ + (x - (K_0 + 2))^+ \\
   f^1(x) &= (x^2 - K_1)^+.
\end{align*}
\]

Assume \(K_0 > s_0\), \(K_1 > (K_0 + 2)^2\) and that these options are traded at prices \(c_0 = 0\) and \(c_1 > 0\) respectively. Set \(c = (c_0, c_1)\). The payoffs of these financial instruments are shown in Figure 1 for \(K_0 = 2\), \(K_1 = 25\):

![Figure 1: Payoffs.](image)

**Definition 4.1.** (1) There exists a *model independent arbitrage* (in the sense of Acciaio et al. [AB16]) if \(\exists (H, h) \in \mathcal{H} \times \mathbb{R}^2\) such that \((H \cdot S)_T(\omega) + h(\Phi(\omega) - c) > 0\) \(\forall \omega \in \Omega\).

(2) There exists a *one point arbitrage* (in the sense of [BFM16]) if \(\exists (H, h) \in \mathcal{H} \times \mathbb{R}^2\) such that \((H \cdot S)_T(\omega) + h(\Phi(\omega) - c) \geq 0\) \(\forall \omega \in \Omega\) and \((H \cdot S)_T(\omega) + h(\Phi(\omega) - c) > 0\) for some \(\omega \in \Omega\).

It is clear that any long position in the option \(\phi^0\) is a one point arbitrage but it is not a model independent arbitrage. We have indeed that there are No Model Independent Arbitrage as:

\[\mathcal{M}_\Phi \neq \emptyset.\]

More precisely, any \(Q \in \mathcal{M}_\Phi\) must satisfy \(Q((K_0, K_0 + 2)) = 0\), so that \((K_0, K_0 + 2)\) is an \(\mathcal{M}_\Phi\)-polar set, nevertheless,

\[\Omega_\Phi = \mathbb{R}^+ \setminus (K_0, K_0 + 2).\]

One possible way to see this is to observe that on \(\Gamma := \mathbb{R}^+ \setminus (K_0, K_0 + 2)\) the option \(\phi^0\) has zero payoff and zero initial cost so that any probability \(P\), with \(\text{supp}(P) \subseteq \Gamma\), that is a martingale measure

---

9
for $S^1, \phi^1$, is also a martingale measure for $S^0, S^1, \phi^0, \phi^1$. Take now $\omega_1 = 0, \omega_2 \in (K_0 + 2, \sqrt{K_1}), \omega_3 > \sqrt{K_1 + c_1}$ and observe that the corresponding points $x_1 := (-s_0, -c_1), x_2 := (\omega_2 - s_0, -c_1)$ and $x_3 := (\omega_3 - s_0, \phi^3(\omega_3) - c_1)$ clearly belong to $\text{conv}(\Delta X(\omega) \mid \omega \in \Gamma)$ where $\Delta X$ is the random vector $[S^1 - s_0; \phi^1 - c_1]$. Consider now $\varepsilon := \frac{1}{\Delta} \min\{c_1, s_0, |\omega_2 - s_0|\}$ so that for $\omega_3$ sufficiently large we have

$$B_\varepsilon(0) \subseteq \text{conv}(\Delta X(\omega) \mid \omega \in \{\omega_1, \omega_2, \omega_3\}) \subseteq \text{conv}(\Delta X(\omega) \mid \omega \in \Gamma).$$

We have therefore that 0 is in the interior of $\text{conv}(\Delta X(\omega) \mid \omega \in \Gamma)$ and from Corollary 4.11 item 1) in [BFM16], $\Omega_\phi = \Gamma = \mathbb{R}^\times \setminus (K_0, K_0 + 2)$. Note, moreover, that this is true for any value of the price $c_1 > 0$.

Consider now the digital options $g_i = F_i(S_T), i = 1, 2,$ with

$$F_1(x) = 1_{(K_0, K_0+2)}(x),$$
$$F_2(x) = 1_{[K_0, K_0+2]}(x)$$

which differ only at the extreme points of the interval $(K_0, K_0 + 2)$ and observe that $F_2$ is upper semi-continuous while $F_1$ is not. From the previous remark $g_1$ has price zero under any martingale measure $Q \in \mathcal{M}_\phi$, so that

$$\sup_{Q \in \mathcal{M}_\phi} E_Q[g_1] = 0. \tag{20}$$

Define:

$$\pi_\Omega(g) := \inf \{x \in \mathbb{R} \mid \exists (H, h) \in \mathcal{H} \times \mathbb{R}^2 \text{ such that } x + (H \cdot S)_T(\omega) + h\Phi(\omega) \geq g(\omega) \forall \omega \in \Omega\}$$

and recall that

$$\pi_\phi(g) := \inf \{x \in \mathbb{R} \mid \exists (H, h) \in \mathcal{H} \times \mathbb{R}^2 \text{ such that } x + (H \cdot S)_T(\omega) + h\Phi(\omega) \geq g(\omega) \forall \omega \in \Omega_\phi\}$$

**Claim 4.2.** In this market:

1. $\pi_\phi(g_1) = \sup_{Q \in \mathcal{M}_\phi} E_Q[g_1] = 0$ and $\pi_\phi(g_2) = \sup_{Q \in \mathcal{M}_\phi} E_Q[g_2];$
2. $\pi_\Omega(g_1) = \min \left\{\frac{\pi_\phi}{\pi_\phi}, 1\right\} > \sup_{Q \in \mathcal{M}_\phi} E_Q[g_1] = 0;$
3. $\pi_\Omega(g_2) = \sup_{Q \in \mathcal{M}_\phi} E_Q[g_2].$

**Remark 4.3.** (i) Item (1) is in agreement with the conclusion of Theorem 1.2.

(ii) Item (2) shows instead that the superhedging duality with respect to the whole $\Omega$ does not hold for the claim $g_1$ (which is even bounded). Note that in this example all the hypothesis of Theorem 1.4 in [AB16] are satisfied except for the upper semi-continuity of $g_1$.

As the comparison between $g_1$ and $g_2$ in items (2) and (3) shows, the assumption of upper semi-continuity of the claim seems artificial from the financial point of view, even though necessary for the validity of Theorem 1.4 in [AB16].

Our results demonstrates that it is possible to obtain a superhedging duality on the relevant set $\Omega_\phi$ (or $\Omega_\phi$ when there are no options) for *any measurable claim*, regardless of the continuity assumptions (as well as without the existence of an option with super-linear payoff).
Proof of the Claim 4.2. Item (1) holds thanks to Theorem 1.1 since in the one-period model there is no difference between dynamic and static hedging. Notice also that the equalities \( \pi \Phi(g_1) = 0 = \sup_{Q \in \mathcal{M}} E_Q[g_1] \) are consequences of (20) and the fact that \((H, h) = (0, 0)\) is a superhedging strategy for \(g_1\) on \(\Omega\). As \(g_2\) is upper semi-continuous, the superhedging duality in item (3) holds thanks to Theorem 1.4 in [AB16], see (7). In the remaining of this section we conclude the proof by showing \(\pi \Omega(g_1) = \min\{s_0, K_0\} = s_0\) (by the assumption \(K_0 > s_0\)) and hence item (2).

Let us consider the model independent superhedging strategies i.e. the set of \((H, h) \in \mathbb{R}^2 \times \mathbb{R}^2\) such that \(x + (H \cdot S)_T(\omega) + h\Phi(\omega) \geq g_1(\omega)\) for any \(\omega \in \Omega\). Any admissible trading strategy is given by \((H, h) := [H^0, H^1, h^0, h^1] \in \mathbb{R}^4\) which correspond to positions in the securities \([S^0, S^1, \phi^0, \phi^1]\) so that

\[
\text{price: } V_0(H, h) := H^0 + H^1s_0 + h^1c_1
\]
\[
\text{payoff: } V_T(H, h) := H^0 + H^1\omega + h^0\phi^0(\omega) + h^1\phi^1(\omega)
\]  

(21)

Trivial super-hedges There are two immediate strategies whose terminal payoff is a super-hedge for \(g_1\).

1. \(S^0\) (i.e. \(H^0 = 1\) in (21) and \(H^1 = h^0 = h^1 = 0\)) with initial cost 1.

2. \(\frac{1}{K_0}S^1\) (i.e. \(H^1 = \frac{1}{K_0}\) in (21) and \(H^0 = h^0 = h^1 = 0\)) with initial cost \(\frac{s_0}{K_0}\).

Consider now a generic superhedging strategy \((H, h)\) for the option \(g_1\) and suppose first that \(H^1 \geq 0\).

Observe that for every \(\omega \in [0, K_0]\) we have: \(V_T(H, h)(\omega) = H^0 + H^1\omega\) and \(g_1(\omega) = 0\). If \(H^0 < 0\) there exists \(\tilde{\omega} \in [0, K_0]\) such that \(H^0 + H^1\tilde{\omega} < 0 = g_1(\tilde{\omega})\) so that the strategy does not dominate the payoff of \(g_1\). Necessarily \(H^0 \geq 0\).

\(h^1 \neq 0\) is not optimal for super-hedging \(g_1\) If \(h^1 \neq 0\) we necessarily have \(h^1 \geq 0\), otherwise \(V_T(H, h)(\omega) < 0\) for \(\omega\) large enough (because of the super-linearity of \(f^1\)) and \((H, h)\) is not a super-hedge for \(g_1\). Since \(f^1(x) = 0\) on \((K_0, K_0 + 2)\) and \(c_1 > 0\), the most convenient super-hedge is with \(h^1 = 0\) (cfr Figure 2).

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure2.png}
\caption{\(\phi^1\) has no positive wealth on \((K_0, K_0 + 2)\).}
\end{figure}

From now on with no loss of generality \(h^1 = 0\).
$h^0 \neq 0$ is not optimal for super-hedging $g_1$. Since $\phi^0$ has a positive payoff, if $h^0 \neq 0$ we might take $h^0 \geq 0$ otherwise we have a better super-hedge (at the same cost) by replacing $h^0 \phi^0$ with the zero portfolio. Suppose now $h^0 > 0$. By recalling that $H^0, H^1 \geq 0$ we note that $V_T(H,h)$ as in (21) satisfies

$$
\inf_{\omega \in (K_0, K_0+2)} H^0 + H^1 \omega + h^0 \phi^0(\omega) = H^0 + H^1 K_0
$$

so that the same super-hedge is achieved by trading only in $S^0$ and $S^1$. In other words with no loss of generality $h^0 = 0$ (cfr Figure 3).

![Diagram](image)

**Figure 3:** $h^0 \phi^0$ does not dominate $g_1$ on $(K_0, K_0 + \varepsilon)$ for any $h^0$ with $\varepsilon = \varepsilon(h^0)$

We finally discuss the case $H^1 < 0$. This is, in general, a more expensive choice for the strategy $(H,h)$. Indeed we have, for instance, that for $\tilde{\omega} = K_0 + 1$, $H^1 S^1(\tilde{\omega}) = H^1(K_0 + 1) < 0$ while $g_1(\tilde{\omega}) = 1$. Since for any strategy $(H,h) \in \mathbb{R}^4$, $V_T(H,h)(\tilde{\omega}) = H^0 + H^1 \tilde{\omega}$ we need $H^0 \geq 1 - H^1(K_0 + 1)$, hence, the initial price $V_0(H,h) \geq 1 - H^1(K_0 + 1 - s_0)$. By choosing the parameters $s_0, K_0$ such that $K_0 + 1 - s_0 < 0$ any superhedging strategy with $H^1 < 0$ is more expensive than the trivial super-hedge given by $H^0 = 1, H^1 = h^0 = h^0 = 0$. Note moreover that in order to cover the losses in $H^1 S^1$ for large value of $\omega$ we would need to take a long position in the option $\phi^1$ (whose payoff dominates $S^1$) for an additional cost of $h^1 c_1 > 0$ with $h^1 > -H^1 > 0$.

We can conclude that the cheapest super-replicating strategies are, in general, given by $H^0 S^0 + H^1 S^1$ with $H^0, H^1 \geq 0$ and it is easy to see that

$$
\pi_\Omega(g_1) = \min \left\{ \frac{s_0}{K_0}, 1 \right\} = \frac{s_0}{K_0} > 0.
$$

\[\square\]

## 5 Technical results and proofs

Recall that $\{\mathcal{F}_t\}_{t \in I}$ is the universal filtration which satisfies in particular that $\mathcal{F}_t$ contains the family of analytic sets of $(\Omega, \mathcal{F}_t^S)$ for any $t \in I$. 

12
We indicate by $Mat(d \times (T + 1); \mathbb{R})$ the space of $d \times (T + 1)$ matrices with real entries representing the set of all the possible trajectories of the price process: for every $\omega \in \Omega$ we have $(S_0(\omega), S_1(\omega), ..., S_T(\omega)) = Mat(d \times (T + 1); \mathbb{R})$. Fix $t \leq T$: we indicate $S_{0:t} = (S_0, S_1, ..., S_t)$ and recall that $S_{0:t}^{-1}(A) = \{\omega \in \Omega \mid S_{0:t}(\omega) \in A\}$ for $A \subseteq Mat(d \times (t + 1); \mathbb{R})$. We set $\Delta S_t := S_t - S_{t-1}$, \( t = 1, ..., T \).

5.1 $\Omega_*$ and $\Omega_\Phi$ are analytic sets

Lemma 5.1. The set $\mathcal{P}_f = \{ P \in \mathcal{P} \mid P \text{ has finite support} \}$ is an analytic subset of $\mathcal{P}$ endowed with the sigma-algebra generated by the $\sigma(\mathcal{P}, C_b)$ topology.

Proof. Set $E = \{ \delta_\omega \mid \omega \in \Omega \}$ which is $\sigma(\mathcal{P}, C_b)$ closed (Th. 15.8 [AB06]) and observe that $\mathcal{P}_f$ is the convex hull of $E$. Consider for any $n \in \mathbb{N}$ the simplex $\Delta_n \subset \mathbb{R}^n$ and the map

$$\gamma_n : E^n \times \Delta_n \longrightarrow \mathcal{P}_f$$

defined by $\gamma_n(\delta_{\omega_1}, \delta_{\omega_n}, \lambda_1, ..., \lambda_n) = \sum_{i=1}^{n} \lambda_i \delta_{\omega_i}$ which is a continuous function in the product topology. Since $E^n \times \Delta_n$ is closed in the product topology of the Borel Space $\mathcal{P}^n \times \mathbb{R}^n$, then the image $\gamma_n(E^n \times \Delta_n)$ is analytic (Proposition 7.40 [BS78]). Finally we notice that $\mathcal{P}_f = \bigcup_n \gamma_n(E^n \times \Delta_n)$ which is therefore analytic, being countable union of analytic sets.

Definition 5.2. Let $\mathcal{L}^\infty(\Omega, \mathcal{F}) := \{ f \in \mathcal{L}(\Omega, \mathcal{F}) \mid f \text{ is bounded} \}$. A subset $U \subseteq \mathcal{P}_f$ is countably determined if there exists a countable set $L \subseteq \mathcal{L}^\infty(\Omega, \mathcal{F})$ such that

$$U := \{ \mu \in \mathcal{P}_f \mid E_\mu[f] \leq 0, \forall f \in L \}$$

Lemma 5.3. If $U \subseteq \mathcal{P}_f$ is countably determined then it is analytic.

Proof. For each $f_n \in L$ define

$$F_n : \mathcal{P} \rightarrow \mathbb{R} \text{ such that } F_n(\mu) = \int_{\Omega} f_n d\mu.$$ 

From Theorem 15.13 in [AB06], $F_n$ is Borel measurable so that

$$U := \{ \mu \in \mathcal{P}_f \mid E_\mu[f_n] \leq 0 \text{ for all } n \in \mathbb{N} \} = \bigcap_{n \in \mathbb{N}} (F_n)^{-1}(-\infty, 0] \cap \mathcal{P}_f$$

is analytic, being countable intersection of analytic sets.

Lemma 5.4. Let $Z_1(\omega) := \max_{i=1,...,d} \max_{t=0,...,T} |S^i_0(\omega)|$, $Z_2(\omega) := \max_{j=1,...,k} |\phi^j(\omega)|$ and $Z = \max(Z_1, Z_2)$ then

$$\mathcal{P}_Z = \left\{ \mu \in \mathcal{P}_f \mid \exists \mathcal{Q} \in \mathcal{M}_f \text{ such that } \frac{d\mathcal{Q}}{d\mu} = \frac{c(\mu)}{1 + Z} \right\}$$

$$\mathcal{P}_{Z,\Phi} = \left\{ \mu \in \mathcal{P}_f \mid \exists \mathcal{Q} \in \mathcal{M}_\Phi \text{ such that } \frac{d\mathcal{Q}}{d\mu} = \frac{c(\mu)}{1 + Z} \right\}$$

are analytic subsets of $\mathcal{P}$ where $c(\mu) = E_\mu[(1 + Z)^{-1}]^{-1}$.
Proof. Assume $\mathcal{P}_Z \neq \emptyset$ (resp. $\mathcal{P}_{Z,\Phi} \neq \emptyset$) otherwise there is nothing to prove. Fix any $t \in \{1, \ldots, T\}$. Let $\text{Mat}(d \times t; \mathbb{Q})$ be the countable set of $d \times t$ matrices with rational entries and denote its elements by $q_n, n \in \mathbb{N}$. For $q_n \in \text{Mat}(d \times t; \mathbb{Q})$, consider the set $\{A_{n,m}\}$ with $A_{n,m} = \{\omega \in \Omega \mid S_{0:t-1}(q_n) \in \mathcal{F}_{t-1}\}$, where $B_{1/m}(q_n)$ denotes the ball (in the Euclidean norm of $\text{Mat}(d \times t; \mathbb{R})$) with radius $1/m$ centered in $q_n$. Define
\[
f^i_{n,m} := \left(\frac{S^i_{t} - S^i_{t-1}}{1 + Z}\right) 1_{A_{n,m}} \in \mathcal{L}^\infty(\Omega, \mathcal{F}),
\]
\[
g^j := \left(\frac{\phi^j}{1 + Z}\right) \in \mathcal{L}^\infty(\Omega, \mathcal{F}).
\]

The following sets
\[
\mathcal{U} := \{\mu \in \mathcal{P}_f \mid E_\mu[f^i_{n,m}] = 0 \forall i, n, m\}
\]
\[
\mathcal{U}_\Phi := \{\mu \in \mathcal{P}_f \mid E_\mu[f^i_{n,m}] = 0 \text{ and } E_\mu[g^j] = 0 \forall i, n, m, j\}
\]
are analytic since they are countably determined. We now show that $\mathcal{U} = \mathcal{P}_Z$ and $\mathcal{U}_\Phi = \mathcal{P}_{Z,\Phi}$ and this will complete the proof.

For any fixed $\mu \in \mathcal{U}$ we have by construction:
\[
\int_{\Omega} \frac{S^i_t}{1 + Z} 1_{A_{n,m}} \, d\mu = \int_{\Omega} \frac{S^i_{t-1}}{1 + Z} 1_{A_{n,m}} \, d\mu \quad \text{for every } A_{n,m}.
\]

Consider the finite set of matrices $\{s_j\}_{j=1}^h := \{S_{0:t-1}(\omega) \in \text{Mat}(d \times t; \mathbb{R}) \mid \omega \in \text{supp}(\mu)\}$ where $h = h(\mu)$ depends on $\mu$. For every $j = 1, \ldots, h$ there exists $q_{m(j)}$ such that $s_j \in B_{1/m(j)}(q_{m(j)})$ and the balls $B_{1/m(j)}(q_{m(j)})$ are all disjoint. Therefore $A_{n(j),m(j)}$ is such that
\[
\mu(B_j) = \mu(A_{n(j),m(j)})
\]
where $B_j := \{S_{0:t-1} = s_j\}$. Since $\{B_j\}_{j=1}^h$ are atoms for $\mu$ in $\mathcal{F}_{t-1}$, we conclude that
\[
\int_{\Omega} \frac{S^i_t}{1 + Z} 1_{B_j} \, d\mu = \int_{\Omega} \frac{S^i_{t-1}}{1 + Z} 1_{B_j} \, d\mu \quad \text{for every } j = 1, \ldots, h
\]
and $E_\mu\left(\frac{S^i_t}{1 + Z} \mid \mathcal{F}_{t-1}\right) = E_\mu\left(\frac{S^i_{t-1}}{1 + Z} \mid \mathcal{F}_{t-1}\right)$. Define $Q$ by $\frac{dQ}{d\mu} := \frac{c}{1 + Z}$ where $c := c(\mu) > 0$ is the normalization constant. Then, $Q \sim \mu, Q \in \mathcal{P}_f$ and:
\[
E_\mu\left(\frac{S^i_t}{1 + Z} \mid \mathcal{F}_{t-1}\right) = E_\mu\left(\frac{S^i_{t-1}}{1 + Z} \mid \mathcal{F}_{t-1}\right) \quad \text{if and only if } E_Q\left(S^i_t \mid \mathcal{F}_{t-1}\right) = S^i_{t-1}.
\]

Thus we can conclude $Q \in \mathcal{M}_f$ and $\mathcal{U} \subseteq \mathcal{P}_Z$. Take now $\mu \in \mathcal{P}_Z$ then there exists $Q$ such that $E_Q\left(S^i_t \mid \mathcal{F}_{t-1}\right) = S^i_{t-1}$ and $\frac{dQ}{d\mu} = \frac{c}{1 + Z}$. From Equation (24) we have that condition (23) holds and hence $\mu \in \mathcal{U}$.

Recall that $\mathcal{M}_{\Phi}$ is defined in (4) and consider now $\mu \in \mathcal{U}_\Phi \subseteq \mathcal{U}$. Then there exists $Q \in \mathcal{M}_f$ such that $\frac{dQ}{d\mu} = \frac{c(\mu)}{1 + Z}$. Moreover $E_\mu[g^j] = 0$ for every $j = 1, \ldots, k$ so that, by (22), $E_Q[\phi^j] = 0$. In this way $\mathcal{U}_\Phi \subseteq \mathcal{P}_{Z,\Phi}$. Take now $\mu \in \mathcal{P}_{Z,\Phi}$ then $\mu \in \mathcal{P}_Z$ from the previous part of the proof. Moreover there exists $Q \in \mathcal{M}_f$ such that $E_Q[\phi^j] = 0$ and $\frac{dQ}{d\mu} = \frac{c}{1 + Z}$. Again by (22) we have $E_\mu[g^j] = 0$ for every $j = 1, \ldots, k$ and hence $\mu \in \mathcal{U}_\Phi$.

Proposition 5.5. $\Omega_*$ and $\Omega_\Phi$ are analytic subsets of $(\Omega, \mathcal{F})$. 

Consider a dense subset \( \{ \omega_i \}_{i=1}^{\infty} \) of \( \Omega \). For any \( n = (n_1, \ldots, n_k, \ldots) \in \mathbb{N}^\mathbb{N} \) we denote by \( n(1), \ldots, n(k) \) the first \( k \) terms (i.e. \( n_1, \ldots, n_k \)). Define

\[
A_{n(1)} := B_1(\omega_{n(1)}),
\]

Let now \( \{ \omega_{n(1), i} \}_{i=1}^{\infty} \) a dense subset of \( A_{n(1)} \) we define

\[
A_{n(1), n(2)} := B_2(\omega_{n(1), n(2)}) \cap A_{n(1)}.
\]

At the \( k^{th} \) step we shall have \( \{ \omega_{n(1), \ldots, n(k-1), i} \}_{i=1}^{\infty} \) a dense subset of \( A_{n(1), \ldots, n(k-1)} \) and we define the closed set

\[
A_{n(1), \ldots, n(k)} := B_k(\omega_{n(1), \ldots, n(k)}) \cap A_{n(1), \ldots, n(k-1)}.
\]

Notice that for any \( \omega \in \Omega \) there will exists an \( n \in \mathbb{N}^\mathbb{N} \) such that

\[
\bigcap_{k \in \mathbb{N}} A_{n(1), \ldots, n(k)} = \{ \omega \}.
\]

We consider the nucleus of the Souslin scheme given by

\[
\bigcup_{n \in \mathbb{N}^\mathbb{N}} \bigcap_{k \in \mathbb{N}} A_{n(1), \ldots, n(k)} \times \{ Q \in \mathcal{P}_Z \mid Q(A_{n(1), \ldots, n(k)}) > 0 \}
\]

Observe that \( A_{n(1), \ldots, n(k)} \) closed in \( \Omega \) implies \( \{ Q \in \mathcal{P} \mid Q(A_{n(1), \ldots, n(k)}) \geq \frac{1}{m} \} \) is \( \sigma(\mathcal{P}, C_b) \)-closed from Corollary 15.6 in [AB06]. Therefore

\[
\{ Q \in \mathcal{P} \mid Q(A_{n(1), \ldots, n(k)}) > 0 \} = \bigcup_m \{ Q \in \mathcal{P} \mid Q(A_{n(1), \ldots, n(k)}) \geq \frac{1}{m} \}
\]

is Borel measurable in \( (\mathcal{P}, \sigma(\mathcal{P}, C_b)) \). By Lemma 5.3 we have that \( \{ Q \in \mathcal{P}_Z \mid Q(A_{n(1), \ldots, n(k)}) > 0 \} \) is analytic. We can conclude that \( A_{n(1), \ldots, n(k)} \times \{ Q \in \mathcal{P}_Z \mid Q(A_{n(1), \ldots, n(k)}) > 0 \} \) is an analytic subset of \( \Omega \times \mathcal{P} \) (which is a Polish space).

From Lemma 5.3 we observe that any \( \mu \in \mathcal{P}_Z \) admits an equivalent martingale measure with finite support. From \( \Omega_* = \{ \omega \in \Omega \mid \exists Q \in \mathcal{M}_Z \text{ s.t. } Q(\omega) > 0 \} \), if \( \omega \notin \Omega_* \), then \( \omega \notin supp(\mu) \) for any \( \mu \in \mathcal{P}_Z \). Taking (25) into account, if \( \omega \notin \Omega_* \) we can find a large enough \( k \) such that

\[
A_{n(1), \ldots, n(k)} \cap \mathcal{P}(\mu) = \emptyset.
\]

We then have

\[
\bigcap_{k \in \mathbb{N}} A_{n(1), \ldots, n(k)} \times \{ Q \in \mathcal{P}_Z \mid Q(A_{n(1), \ldots, n(k)}) > 0 \} = \begin{cases} \{ \omega \} \times \mathcal{P}_\omega & \text{if } \omega \in \Omega_* \\ \emptyset & \text{if } \omega \notin \Omega_* \end{cases},
\]

where \( \mathcal{P}_\omega = \{ Q \in \mathcal{P}_Z \mid Q(\{ \omega \}) > 0 \} \).

From Proposition 7.35 and Proposition 7.41 in [BS78] any kernel of a Souslin scheme of analytic sets is again an analytic set. Then

\[
\bigcup_{n \in \mathbb{N}^\mathbb{N}} \bigcap_{k \in \mathbb{N}} A_{n(1), \ldots, n(k)} \times \{ Q \in \mathcal{P}_Z \mid Q(A_{n(1), \ldots, n(k)}) > 0 \}
\]

is an analytic set in \( \Omega \times \mathcal{P} \) whose projection on \( \Omega \), thanks to (27), is equal to \( \Omega_* \). Since the projection \( \Pi : \Omega \times \mathcal{P} \to \Omega \) is continuous we finally deduce that \( \Omega_* \) is analytic.

For \( \Omega_\Phi \) repeat the same proof replacing \( \mathcal{P}_Z \) with \( \mathcal{P}_{Z, \Phi} \). \( \square \)
Remark 5.6. Let \( \hat{\Omega} \subseteq \Omega \) be an analytic subset of \((\Omega, \mathcal{F})\). An inspection of the proof shows that

\[
\hat{\Omega}_* := \{ \omega \in \hat{\Omega} \mid \exists Q \in \mathcal{M}_f \text{ s.t. } Q(\hat{\Omega}) = 1 \text{ and } Q(\omega) > 0 \}
\]

\[
\hat{\Omega}_\phi := \{ \omega \in \hat{\Omega} \mid \exists Q \in \mathcal{M}_\phi \text{ s.t. } Q(\hat{\Omega}) = 1 \text{ and } Q(\omega) > 0 \}
\]

are also analytic subsets of \((\Omega, \mathcal{F})\). Indeed, \( \mathcal{P}_{\hat{\Omega}} := \{ P \in \mathcal{P} \mid P(\hat{\Omega}) = 1 \} \) is an analytic subset of \( \mathcal{P} \), by Proposition 7.43 in [BS78], therefore \( \mathcal{P}_Z \cap \mathcal{P}_{\hat{\Omega}} \) is analytic and one may replace in the above proof \( \mathcal{P}_Z \) with \( \mathcal{P}_Z \cap \mathcal{P}_{\hat{\Omega}} \) and \( \Omega_* \) with \( \hat{\Omega}_* \) to obtain the conclusion.

Remark 5.7. In one-period markets \((T = 1), \Omega_* \) is a Borel measurable set. To see this observe that if there are no one point arbitrages then \( \Omega_* = \Omega = \mathcal{B}(\Omega) \) by Corollary 4.11 in [BFM16]. When this condition is violated, there exists a strategy \( H^1 \in \mathbb{R}^d \) such that \( H^1 \cdot (S_1 - S_0) \geq 0 \) and \( B^1 := \{ \omega \in \Omega \mid H^1 \cdot (S_1(\omega) - S_0) > 0 \} \) is non-empty and Borel measurable. Indeed \( B^1 = (f \circ S_1)^{-1}(0, \infty) \) with \( f(x) := H^1 \cdot (x - S_0) \) continuous and \( S_1 \) Borel measurable. Observe now that, restricted to the set \( \Omega \setminus B^1 \), one asset is redundant (say \( S^d \)) so that the market can be described by \((S^0, \ldots, S^{d-1})\). If there is no one point arbitrage we have \( \Omega_* = \Omega \setminus B^1 = \mathcal{B}(\Omega) \). Otherwise we can iteratively repeat the same argument to construct \( B^j := \{ \omega \in \Omega \setminus \bigcup_{k=1}^{j-1} B^k \mid H^1 \cdot (S_1(\omega) - S_0) > 0 \} \) and dropping iteratively one additional asset. Since the number of assets is finite the procedure takes \( \beta \leq d \) steps. On the resulting set there are no one point arbitrages so that \( \Omega_* = (\bigcup_{j=1}^\beta B^j)^C \in \mathcal{B}(\Omega) \).

5.2 On the key Proposition 2.1

Remark 5.8. We point out at this stage that \( \Omega_* \) is not only analytic but also it belongs to \( \mathcal{F}_T \) where \( \mathcal{F}_T \) is the universal completion of \( \sigma(S_t \mid t \leq T) \). Indeed \( \Omega_* \subseteq S_{0:T}^{-1}(\Omega_*^{\langle 0, T \rangle}) \). Moreover for any \( \omega_1 \in S_{0:T}^{-1}(\Omega_*^{\langle 0, T \rangle}) \) there exists \( \omega_2 \in \Omega_* \) such that \( S_{0:T}(\omega_1) = S_{0:T}(\omega_2) \). Therefore for any \( Q \in \mathcal{M}_f \) such that \( Q(\{\omega_1\}) > 0 \) and \( Q(\{\omega_2\}) = 0 \), the measure \( \hat{Q} \) such that \( \hat{Q}(\{\omega_1\}) := Q(\{\omega_1\}), \hat{Q}(\{\omega_2\}) := 0 \) and \( \hat{Q} = Q \) elsewhere is a martingale measure. Necessarily \( \omega_1 \in \Omega_* \).

In the proof of Proposition 2.1 we will make use of the following simple fact: set \( \Omega_*^t := \Omega_* \in \mathcal{F}_t \) then by backward recursion we have

\[
\Omega_*^t := S_{0:t}^{-1}(S_{0:t}(\Omega_*^{t+1})) \in \mathcal{F}_t, \quad \Omega_*^{t+1} \subseteq \Omega_*^t \text{ for any } t = 0, \ldots, T - 1, \text{ and } \Omega_* = \bigcup_{t=1}^T \Omega_*^t.
\]

Notice that \( \Omega_*^t \) can be interpreted as the \( \mathcal{F}_t \)-measurable projection of \( \Omega_* \) since \( \Omega_*^t = S_{0:t}^{-1}(S_{0:t}(\Omega_*)) \).

We also recall that the condition No one point arbitrage holds true on \( \Omega_* \). If indeed there exists \( H \in \mathcal{H} \) such that \( (H \cdot S)_T \geq 0 \) with \( (H \cdot S)_T(\omega) > 0 \) for some \( \omega \in \Omega_* \), then any measure \( P \) such that \( P(\omega) > 0 \) cannot be a martingale measure, which contradicts [1].

5.2.1 Proof of Proposition 2.1

We show, in several steps, that \( \pi_*(g) = \sup_{Q \in \mathcal{M}_f} \pi_Q(g) \) where \( \pi_* \) and \( \pi_Q \) are defined in [10] and [11] and \( g \in \mathbb{L}(\Omega, \mathcal{F}) \).

Step 1: The first step is to construct, for any \( 1 \leq t \leq T \), an \( \mathcal{F}_{t-1} \)-measurable random set \( R_{t,X,D} \subseteq \mathbb{R}^{d+1} \) whose interpretation is the following: if \( \omega \) occurs, any \( H^1, \ldots, H^d, H^{d+1} \in R_{t,X,D}(\omega) \)
represents a strategy at time \( t - 1 \) that allows to super-hedge the random variable \( X \) at time \( t \), for any trajectory in \( D \subseteq \Omega \). Here \( H^{d+1} \) represents the investment in the non-risky asset. Note that we need to incorporate the additional feature given by the choice of the set \( D \) since we want to super-hedge the random variable \( g \) only on \( \Omega_\ast \subseteq \Omega \).

Recall \( \Delta S_t = S_t - S_{t-1} \). Consider, for an arbitrary \( 1 \leq t \leq T, D \in \mathcal{F}_t \) and \( X \in \mathcal{L}(\Omega, \mathcal{F}) \), the multifunction

\[
\psi_{t,X,D} : \omega \mapsto \{ [\Delta S_t(\tilde{\omega}) \cdot 1; X(\tilde{\omega})] D \mid \tilde{\omega} \in \Sigma_{t-1}^\omega \} \subseteq \mathbb{R}^{d+2}
\]

where \( [\Delta S_t; 1; X] D = [\Delta S_t^1 1_D, \ldots, \Delta S_t^d 1_D, 1_D, X 1_D] \) and \( \Sigma_{t-1}^\omega \) is the level set of the trajectory \( \omega \) up to time \( t - 1 \) i.e. \( \Sigma_{t-1}^\omega = \{ \tilde{\omega} \in \Omega \mid S_{0:t-1}(\tilde{\omega}) = S_{0:t-1}(\omega) \} \). We show that \( \psi_{t,X,D} \) is an \( \mathcal{F}_{t-1} \)-measurable multifunction. Indeed we need to show that, for any open set \( O \subseteq \mathbb{R}^d \times \mathbb{R}^2 \),

\[
\{ \omega \in \Omega \mid \psi_{t,X,D}(\omega) \cap O \neq \emptyset \} = S_{0:t-1}^{-1}(S_{0:t-1}(B)) \in \mathcal{F}_{t-1}\text{ where } B = ([\Delta S_t; 1; X] D)^{-1}(O).
\]

First \( [\Delta S_t, 1, X] D \) is an \( \mathcal{F} \)-measurable random vector then \( B \in \mathcal{F} \). Second \( S_u \) is a Borel measurable function for any \( 0 \leq u \leq t - 1 \) so that we have, as a consequence of Theorem III.18 in [DMS82], that \( S_{0:t-1}(B) \) belongs to the sigma-algebra generated by the analytic sets in \( Mat(d \times t; \mathbb{R}) \) endowed with its Borel sigma-algebra. Applying now Theorem III.11 in [DMS82] we deduce that \( S_{0:t-1}^{-1}(S_{0:t-1}(B)) \in \mathcal{F}_{t-1} \) and hence the desired measurability for \( \psi_{t,X,D} \).

By preservation of measurability (see [RW98] for instance) the multifunction

\[
\psi_{t,X,D}^*: \omega \mapsto \{ H \in \mathbb{R}^{d+2} \mid H \cdot y \leq 0 \forall y \in \psi_{t,X,D}(\omega) \}
\]

is also \( \mathcal{F}_{t-1} \)-measurable and thus, the same holds true for \( -\psi_{t,X,D}^* \cap \{ \mathbb{R}^{d+1} \times \{ -1 \} \} \). The projection on the first \( d+1 \) components, \( R_{t,X,D} := \Pi_{x_1, \ldots, x_{d+1}}(\psi_{t,X,D}^* \cap \{ \mathbb{R}^{d+1} \times \{ -1 \} \}) \), provides the building blocks for the super-replicating strategy for \( X \). By the previous construction we have indeed that

\[
R_{t,X,D}(\omega) = \left\{ H \in \mathbb{R}^{d+1} \mid H^{d+1} 1_D + \sum_{i=1}^d H^i \Delta S_t^i(\tilde{\omega}) 1_D \geq X(\tilde{\omega}) 1_D \forall \tilde{\omega} \in \Sigma_{t-1}^\omega \right\}
\]

(29)

Notice that if \( D \cap \Sigma_{t-1}^\omega = \emptyset \) then \( R_{t,X,D}(\omega) = \mathbb{R}^{d+1} \). Note also that \( R_{t,X,D} \) is, by construction, a closed set.

Denote by \( \Pi_{x_{d+1}}(R_{t,X,D}) \) the projection on the \((d+1)\)-th component, which is a random interval in \( \mathbb{R} \) with possible values \( \{ \emptyset \}, \{ \Omega \} \). Observe now that the projection is continuous and that the infimum of a real-valued random set \( A \) preserve the measurability since

\[
\{ \omega \in \Omega \mid \inf \{ a \mid a \in A(\omega) \} < y \} = \{ \omega \in \Omega \mid A(\omega) \cap (-\infty, y) \neq \emptyset \}
\]

Conclude, therefore, that \( X_{t-1} := \inf \Pi_{x_{d+1}}(R_{t,X,D}) \) is an \( \mathcal{F}_{t-1} \)-measurable function with values in \( \mathbb{R} \cup \{ \pm \infty \} \).

**Step 2.** We prove that for every \( \omega \in \{ |X_{t-1}| < \infty \} \) the infimum in \( X_{t-1} \) is actually a minimum. To this aim fix \( \omega \in \{ |X_{t-1}| < \infty \} \) and notice that there might exist \( L \in \mathbb{R}^d \setminus \{ 0 \} \) such that \( L \cdot \Delta S_t = 0 \) on \( \Sigma_{t-1}^\omega \cap \Omega_t^\omega \), meaning that some assets are redundant on this level set. We can reduce the number of assets by selecting \( i_1, \ldots, i_k \in \{ 1, \ldots, d \} \) such that \( l_1 \Delta S_{t,i_1}^1 + \ldots + l_k \Delta S_{t,i_k}^k = 0 \) implies \( l_j = 0 \) for every \( j = 1, \ldots, k \). Consider the closed set

\[
\tilde{R}(\omega) = \{ H \in R_{t,X,D}(\omega) \mid H^{j,i} = 0 \text{ for every } j = 1, \ldots, k \}
\]
and observe that

\[ X_{t-1}(\omega) = \inf_{\Pi_{x_{d+1}}} (R_{t,X,D}(\omega)) = \inf_{\Pi_{x_{d+1}}} (\tilde{R}(\omega)) = \inf_{\Pi_{x_{d+1}}} \left( \tilde{R}(\omega) \cap \{ [X_{t-1}(\omega), X_{t-1}(\omega) + 1] \} \right). \]

The set \( Ko(\omega) := \tilde{R}(\omega) \cap \{ [X_{t-1}(\omega), X_{t-1}(\omega) + 1] \} \) is closed being the intersection of closed sets. We claim that \( Ko(\omega) \) is bounded. By contradiction, suppose it is unbounded. Let \( \hat{H}_n = (H_n, H_n^{d+1}) \in Ko(\omega) \subset \mathbb{R}^d \times \mathbb{R} \), such that \( \| H_n \| \to +\infty \). By definition \( H_n^j = 0 \) for every \( j = 1, \ldots, k \) and \( H_n^{d+1} \) is bounded by \( X_{t-1}(\omega) + 1 \). For any \( \bar{\omega} \in D \cap \Sigma_{t-1}^\omega \) and any \( n \) we have

\[
\frac{X_{t-1}(\omega) + 1}{\| H_n \|} + \frac{H_n}{\| H_n \|} \cdot \Delta S_t(\bar{\omega}) \geq \frac{X_t(\bar{\omega})}{\| H_n \|}.
\]

Since \( \frac{H_n}{\| H_n \|} \) lies on the unit sphere of \( \mathbb{R}^d \), we can extract a subsequence converging to \( H^* \) with \( \| H^* \| = 1 \). Therefore passing to the limit over this subsequence we have \( H^* \cdot \Delta S_t(\bar{\omega}) \geq 0 \) for every \( \bar{\omega} \in D \cap \Sigma_{t-1}^\omega \). From No one point arbitrage condition we deduce \( H^* \cdot \Delta S_t = 0 \) on \( D \cap \Sigma_{t-1}^\omega \). Since \( H_n \in Ko(\omega) \) then \( (H^*)^j = 0 \) on the redundant assets and thus \( H^* = 0 \) which is a contradiction. The set \( Ko(\omega) \) is closed and bounded in \( \mathbb{R}^{d+1} \), hence compact. From the continuity of the projection \( \Pi_{x_{d+1}}(Ko(\omega)) \) is compact, so that the infimum is attained.

**Step 3:** We now provide a backward procedure which yields the super-replication price and the corresponding optimal strategy. By classical arguments, when we fix a reference probability \( Q \in \mathcal{M}_f \) this procedure yields two processes \( X_t(Q) \) and \( H_t(Q) \) such that

\[
g \leq \sum_{u=t+1}^{T} H_u(Q) \cdot \Delta S_u + X_t(Q) = \sum_{t=1}^{T} H_t(Q) \cdot \Delta S_t + X_0(Q) \quad Q \text{-a.s.} \quad (30)
\]

where \( X_t(Q) \) represents the minimum amount of cash that we need at time \( t \) in order to super-hedge \( g \) in the \( Q \)-a.s. sense. Recall that from \( NA(Q) \) we necessarily have \( X_t(Q) > -\infty \) on \( supp(Q) \). With no loss of generality set \( X_t(Q)(\omega) = -\infty \) for any \( \omega \notin supp(Q) \). Now we prove the pathwise counterpart of (30):

Set \( X_T := g \) and \( D_T := \Omega_\ast \) which belongs to \( \mathcal{F}_T \) by Remark 5.8 and consider first the random set \( R_{T,X_T,D_T} \). The random variable \( X_{T-1} := \inf \Pi_{x_{d+1}}(R_{T,X_T,D_T}) \) represents the minimum amount of cash that we need at time \( T - 1 \) in order to super-hedge \( g \) on \( \Omega_\ast \). \( X_{T-1} \) is therefore the \( \mathcal{F}_{T-1} \)-measurable random variable that needs to be super-replicated at time \( T - 2 \).

For \( t = T - 1, \ldots, 0 \) we indeed iterate the procedure by taking \( X_{t+1} := \inf \Pi_{x_{d+1}}(R_{t+1,X_{t+1},D_{t+1}}) \), \( D_{t+1} = S_{0\Delta_t}^{-1}(S_{0\Delta_t}(D_{t+1})) \in \mathcal{F}_t \) and the random set \( R_{t+1,X_{t+1},D_{t+1}} \) as defined before. We again have that \( X_t \) is an \( \mathcal{F}_t \)-measurable function with values in \( \mathbb{R} \cup \{ \pm \infty \} \).

This backward procedure yields the super-hedging price \( X_0 \) on \( \Omega_\ast \) but also provide the corresponding cheapest portfolio as follows: note first that for every \( \omega \in \Omega_\ast \), \( X_t(\omega) > -\infty \). If this is not the case there exists a sequence \( (H_n, x_n)_{n \in \mathbb{N}} \in \mathbb{R}^d \times \mathbb{R} \) such that \( x_n \downarrow -\infty \), \( x_n + H_n \Delta S_{t+1}(\bar{\omega}) \geq X_{t+1}(\bar{\omega}) \) for every \( \bar{\omega} \in D_{t+1} \cap \Sigma_{t+1}^\omega \) and hence \( Q \)-a.s. for every \( Q \in \mathcal{M}_f \) such that \( Q(\Sigma_{t+1}^\omega) > 0 \). This would lead to a contradiction with \( X_t(Q) > -\infty \). From now on we therefore assume that
$X_t(\omega) > -\infty$. In the case $X_t(\omega) < \infty$ for every $t = 0, \ldots, T - 1$, Step 2 provides that $X_t$ is actually a minimum. The $\mathcal{F}_t$-measurable multifunction given by $\Pi_{x_{t+1}}(R_{t+1}, X_{t+1}, D_{t+1} \cap \{\mathbb{R}^d \times X_t\})$ is therefore non-empty for every $t = 0, \ldots, T - 1$ and thus admits a measurable selector $H_{t+1}$. The strategy $H_1, \ldots, H_T$ satisfy the inequalities

\[
g \leq H_T \cdot \Delta S_T + X_{T-1} \quad \text{on } D_T
\]

\[
X_{T-1} \leq H_{T-1} \cdot \Delta S_{T-1} + X_{T-2} \quad \text{on } D_{T-1}
\]

\[\ldots\]

\[
X_1 \leq H_1 \cdot \Delta S_1 + X_0 \quad \text{on } D_1
\]

and it represents a super-hedge on $\Omega_* = \bigcap_{t=1}^T D_t$ as

\[
g \leq H_T \cdot \Delta S_T + X_{T-1} \leq \sum_{t=T-1}^T H_t \cdot \Delta S_t + X_{T-2} \leq \ldots \leq \sum_{t=1}^T H_t \cdot \Delta S_t + X_0 \quad (31)
\]

holds true for any $\omega \in \Omega_*$. When instead $X_t(\omega) = \infty$ for some $\omega \in \Omega_*$ and for some $t \geq 0$ then by simply taking $X_u \equiv \infty$ and $H_u$ arbitrary for every $u \leq t$, the inequality (31) is trivially satisfied.

**Step 4:** In order to prove (12) we recursively show that $X_t(\omega) = \sup_{Q \in \mathcal{M}_f} X_t(Q)(\omega)$ for any $\omega \in \Omega_*$ which, in particular, implies $X_0 = \sup_{Q \in \mathcal{M}_f} X_0(Q)$. Obviously $X_t(\omega) \geq X_t(Q)(\omega)$ for any $\omega \in \Omega_*$ so that $X_t \geq \sup_{Q \in \mathcal{M}_f} X_t(Q)$. Thus, we need only to prove the reverse inequality.

For $t = T$ the claim is obvious: $X_T = g$. By backward recursion suppose now it holds true for any $u$ with $t + 1 \leq u \leq T$ i.e. $X_u(\omega) = \sup_{Q \in \mathcal{M}_f} X_u(Q)(\omega)$ for any $\omega \in \Omega_*$. From the recursive hypothesis in order to find a super-replication strategy with the same price for any $Q \in \mathcal{M}_f$ we need to super-replicate $X_{t+1}$. We fix a level set $\Sigma^T$ and recall that $X_t$ is $\mathcal{F}_t$-measurable, hence it is constant on $\Sigma^T$. We first treat two trivial cases:

- If $X_{t+1}(\omega) = \infty$ for some $\omega \in \Omega_*$ then the claim is not super-replicable at a finite cost hence the thesis follows with $X_0 = \sup_{Q \in \mathcal{M}_f} X_0(Q) = \infty$.

- If $\Sigma^T \cap \Omega_* = \emptyset$ we have two consequences: $\Sigma^T$ is an $\mathcal{M}_f$-polar set, hence by assumption, $X_t(Q) = -\infty$ on $\Sigma^T$, for any $Q \in \mathcal{M}_f$. Moreover, as explained after equation (29), $\Pi_{x_{t+1}}(R_{t+1}, X_{t+1}, D_{t+1}) = \mathbb{R}$ so that $X_t(\omega) = -\infty$ and the desired equality follows.

From now on we therefore assume $X_{t+1} < \infty$ and $\Sigma^T \cap \Omega_* = \emptyset$. Define, for any $y \in \mathbb{R}$, the set

\[
\Gamma_y := co(\text{conv}\{[\Delta S_{t+1}(\bar{\omega}); y - X_{t+1}(\bar{\omega})] \mid \bar{\omega} \in \Sigma^T \cap \Omega_*\})
\]

We claim that

\[
0 \in int(\Gamma_y) \implies X_t > y \quad (32)
\]

Indeed from $0 \in int(\Gamma_y)$ there is no non zero $(H, h) \in \mathbb{R}^d \times \mathbb{R}$, such that either $h(y - X_{t+1}) + H \cdot \Delta S_{t+1} \geq 0$ or $h(y - X_{t+1}) + H \cdot \Delta S_{t+1} \leq 0$ on $\Sigma^T \cap \Omega_*$. In particular there is no $H \in \mathbb{R}^d$ such that

\[
y + H \cdot \Delta S_{t+1} \geq X_{t+1} \text{ on } \Sigma^T \cap \Omega_* \quad (33)
\]

19
Recalling that, by definition, \( X_t \) is the infimum of real numbers for which \( (33) \) is satisfied, we have \( X_t \geq y \). Since, from Step 2, \( X_t \), when finite, is actually a minimum, we have \( X_t \geq y \) and \( (32) \) follows.

**Premise:** As in Step 1, we may suppose, without loss of generality, that if for some \( H \in \mathbb{R}^d \), \( H \cdot \Delta S_{t+1} = 0 \) on \( \Sigma_t^w \cap \Omega_t^{+1} \) then \( H = 0 \). In fact if this is not the case we can reduce, with an analogous procedure, the number of assets needed for super-replication on the level set.

We now distinguish two cases.

**Case 1:** Suppose there exist \( (H, h, \alpha) \in \mathbb{R}^{d+2} \) with \( (H, h, \alpha) \neq 0 \) such that \( h(y - X_{t+1}) + H \cdot \Delta S_{t+1} = \alpha \) on \( \Sigma_t^w \cap \Omega_t^{+1} \). We claim that \( h \neq 0 \). Indeed, if \( h = 0 \) then \( \alpha \neq 0 \); since \( H \cdot \Delta S_{t+1} = 0 \) implies \( (H, h, \alpha) = 0 \). However, \( \alpha \neq 0 \) implies \( H \cdot \Delta S_{t+1} = \alpha \) on \( \Sigma_t^w \cap \Omega_t^{+1} \) which would yield a trivial one point arbitrage on \( \Omega_* \), hence a contradiction.

Since \( h \neq 0 \) we have \( y - \frac{\alpha}{h} + \frac{h}{H} \cdot \Delta S_{t+1} = X_{t+1} \) on \( \Sigma_t^w \cap \Omega_t^{+1} \); this means that \( X_t \) from Step 3 coincides with \( y - \frac{\alpha}{h} \) and \( X_{t+1} \) is replicable implementing the strategy \( \hat{H} := \frac{H}{h} \) in the risky assets and \( X_t = y - \frac{\alpha}{h} \) in the non-risky assets. If now for some \( Q \in \mathcal{M}_f \) such that \( Q(\Sigma_t^w) > 0 \), we have the existence of \( x \leq X_t \) and \( H_x \in \mathbb{R}^d \) such that \( x + H_x \cdot \Delta S_{t+1} \geq X_{t+1} \) \( Q \)-a.s. then \( x - X_t + (H_x - \hat{H}) \Delta S_{t+1} \geq 0 \) \( Q \)-a.s. hence, since \( NA(Q) \) holds true, \( x \geq X_t \). Therefore \( X_t = X_t(Q) \) on \( \Sigma_t^{w-1} \).

**Case 2:** If a triplet \( (H, h, \alpha) \in \mathbb{R}^{d+2} \) such as in Case 1 does not exist then we define

\[
\bar{y} = \sup \{ y \in \mathbb{R} \mid \exists H \in \mathbb{R}^d : y + H \cdot \Delta S_{t+1} \leq X_{t+1} \text{ on } \Sigma_t^w \cap \Omega_t^{+1} \}.
\]

Obviously \( \bar{y} < X_t \) otherwise we are back to Case 1. For every \( 0 < \varepsilon < X_t - \bar{y} \) and for every \( H \in \mathbb{R}^d \) neither \( X_t - \varepsilon + H \Delta S_{t+1} \geq X_{t+1} \) nor \( X_t - \varepsilon + H \Delta S_{t+1} \leq X_{t+1} \) holds true on \( \Sigma_t^w \cap \Omega_t^{+1} \). Moreover if there exists \( h \in \mathbb{R} \) such that \( h(X_t - \varepsilon - X_{t+1}) + H \Delta S_{t+1} \geq 0 \) (or \( h(X_t - \varepsilon - X_{t+1}) + H \Delta S_{t+1} \leq 0 \)) on \( \Sigma_t^w \cap \Omega_t^{+1} \) necessarily \( h \) would be 0 (otherwise simply divide by \( h \)). In such a case \( H \Delta S_{t+1} \geq 0 \) (or \( H \Delta S_{t+1} \leq 0 \)) on \( \Sigma_t^w \cap \Omega_t^{+1} \) and by absence of one point arbitrage we get \( H \Delta S_{t+1} = 0 \) and hence \( H = 0 \). For this reason neither \( h(X_t - \varepsilon - X_{t+1}) + H \Delta S_{t+1} \geq 0 \) nor \( h(X_t - \varepsilon - X_{t+1}) + H \Delta S_{t+1} \leq 0 \) for any \( (H, h) \in \mathbb{R}^{d+1} \setminus \{0\} \) so that \( 0 \in int \Gamma_{X_t - \varepsilon} \).

Take \( \{\omega_i\}_{i=1}^k \subset \Sigma_t^w \cap \Omega_* \) (with \( k \leq d \)) such that \( \{[\Delta S_{t+1}(\omega_i); X_t - \varepsilon - X_{t+1}(\omega_i)] \mid i = 1, \ldots, k\} \) are linearly independent and generates the same linear space in \( \mathbb{R}^{d+1} \) as \( \Gamma_{X_t - \varepsilon} \). By Proposition \([34]\) and the convexity of the set of martingale measures, there exists \( Q \in \mathcal{M}_f \) such that \( Q(\{\omega_i\}) > 0 \) for any \( i = 1, \ldots, k \). For such a \( Q \) we get

\[
\Gamma_{X_t - \varepsilon} = co(\text{conv}([\Delta S_{t+1}(\bar{\omega}); X_t - \varepsilon - X_{t+1}(\bar{\omega})] \mid \bar{\omega} \in supp(Q) \cap \Sigma_t^w))
\]

so that, from \( 0 \in int \Gamma_{X_t - \varepsilon} \), there exists no \( H(Q) \in \mathbb{R}^d \) such that \( X_t - \varepsilon + H(Q) \cdot \Delta S_{t+1} \geq X_{t+1} \) \( Q \)-a.s. We can conclude that \( X_t \geq \sup_{Q \in \mathcal{M}_f} X_t(Q) \geq X_t - \varepsilon \). Letting \( \varepsilon \downarrow 0 \) we get \( \sup_{Q \in \mathcal{M}_f} X_t(Q) = X_t \) as desired.

**Step 5:** finally we prove \([13]\). Notice that \( C \subseteq \bigcap_{Q \in \mathcal{M}_f} C(Q) \). Moreover if \( g \in \bigcap_{Q \in \mathcal{M}_f} C(Q) \) then \([30]\) holds with \( X_0(Q) \leq 0 \) for every \( Q \in \mathcal{M}_f \). Therefore also in Equation \([31]\) we have \( X_0 = \sup_{Q \in \mathcal{M}_f} X_0(Q) \leq 0 \) and \( g \leq \sum_{i=1}^T H_i \cdot \Delta S_i \) on \( \Omega_* \) i.e. \( g \in C \).
Remark 5.9. Note that the proof of Proposition 2.1 relies only on the fact that \( \Omega_* \) is an analytic set and that \((\Omega_*)^C\) is the maximal polar set for the class of finite support martingale measure. Given \( \hat{\Omega} \subseteq \Omega \) an analytic subset of \((\Omega, \mathcal{F})\), from Proposition 5.5 it also follows that

\[
\hat{\mathcal{C}} = \bigcap_{\{Q \in \mathcal{M}_f | Q(\hat{\Omega}) = 1\}} \mathcal{C}(Q)
\]

where \( \hat{\mathcal{C}} := \{ f \in \mathcal{L}(\Omega, \mathcal{F}) \mid f \leq k \text{ on } \hat{\Omega}_* \text{ for some } k \in \mathcal{K} \} \) and \( \hat{\Omega}_* \) as in (28).

5.3 Proof of Theorem 1.2

Recall that \( \pi_\Phi \) is defined in (6) and \( \mathcal{M}_\Phi \) in (4). Set

\[
\bar{\pi}_\Phi(g) := \inf \{ x \in \mathbb{R} \mid \exists H \in \mathcal{H} \text{ such that } x + (H \cdot S)_T(\omega) \geq g(\omega) \forall \omega \in \Omega_\Phi \}.
\]

Lemma 5.10. Let \( g : \Omega \mapsto \mathbb{R} \) and \( \phi^j : \Omega \mapsto \mathbb{R}, j = 1, \ldots, k \), be \( \mathcal{F} \)-measurable random variables. Then

\[
\pi_\Phi(g) = \inf_{h \in \mathbb{R}^k} \bar{\pi}_\Phi(g - h\Phi).
\]

Proof. For every \( h \in \mathbb{R}^k \) we have \( \pi_\Phi(g) \leq \bar{\pi}_\Phi(g - h\Phi) \) so that \( \pi_\Phi(g) \leq \inf_{h \in \mathbb{R}^k} \bar{\pi}_\Phi(g - h\Phi) \). By contradiction assume \( \pi_\Phi(g) < \inf_{h \in \mathbb{R}^k} \bar{\pi}_\Phi(g - h\Phi) \), then there exist \( (\bar{x}, \bar{h}, \bar{H}) \in (\mathbb{R}, \mathbb{R}^k, \mathcal{H}) \) such that

\[
\bar{x} < \inf_{h \in \mathbb{R}^k} \bar{\pi}_\Phi(g - h\Phi) \quad \text{and} \quad \bar{x} + (\bar{H} \cdot S)_T(\omega) + \bar{h}\Phi(\omega) \geq g(\omega) \text{ for all } \omega \in \Omega_\Phi.
\]

Clearly we have a contradiction since

\[
\bar{x} \leq \bar{\pi}_\Phi(g - \bar{h}\Phi) = \inf \{ x \in \mathbb{R} \mid \exists H \in \mathcal{H} \text{ s. t. } x + (H \cdot S)_T(\omega) \geq g(\omega) \forall \omega \in \Omega_\Phi \} \leq \bar{x}.
\]

Proof of Theorem 1.2. Since also \( \Omega_\Phi \) is analytic (Proposition 5.5), by comparing the definition of \( \Omega_\Phi \) in (5) with (16), we may repeat step by step the same arguments used in the proof of Theorem 1.1 and Proposition 2.1 replacing \( \Omega_* \) with \( \Omega_\Phi \). We then conclude that \( \bar{\pi}_\Phi(g) = \sup_{Q \in \mathcal{M}_f | \supp(Q) \subseteq \Omega_\Phi} E_Q[g] \) for any \( \mathcal{F} \)-measurable random variable \( g \). From the hypothesis we also have \( \bar{\pi}_\Phi(g) = \sup_{Q \in \mathcal{M}_\Phi} E_Q[g] \). Since \( E_Q[h\Phi] = 0 \) for all \( Q \in \mathcal{M}_\Phi \) and \( h \in \mathbb{R}^k \), for the \( \mathcal{F} \)-measurable random variable \( g - h\Phi \) we have

\[
\bar{\pi}_\Phi(g - h\Phi) = \sup_{Q \in \mathcal{M}_\Phi} E_Q[g - h\Phi] = \sup_{Q \in \mathcal{M}_\Phi} E_Q[g], \forall h \in \mathbb{R}^k.
\]

The Lemma 5.10 then implies: \( \pi_\Phi(g) = \inf_{h \in \mathbb{R}^k} \bar{\pi}_\Phi(g - h\Phi) = \sup_{Q \in \mathcal{M}_\Phi} E_Q[g] \).
