I. INTRODUCTION

Actinide dioxides form a group of important materials from technological viewpoints of a nuclear reactor fuel and a heterogeneous catalyst. On the other hand, this material group has been actively investigated also from a viewpoint of basic science because of its high symmetry of the fluorite structure of the space group $Fm\bar{3}m$.

In the circumstance of such high symmetry of crystal structure, it is possible to observe peculiar ordering of multipole higher than dipole, when we change the kind of actinide ions. Among several magnetic properties of actinide dioxides, a mysterious low-temperature ordered phase of NpO$_2$ has attracted continuous attention in the research field of condensed matter physics.

The phase transition in NpO$_2$ has been confirmed in 1953 from the observation of a peak in the specific heat around 25 K. Due to the behavior of magnetic susceptibility, it has been first considered that the antiferromagnetic order occurs. Unfortunately, no dipole moments have been observed in the low-temperature phase and a puzzling situation has continued. Neutron scattering experiments have revealed that the ground state of the crystalline electric field (CEF) potential is $\Gamma_8$, which carries multipole moments. Then, from several phenomenological works on the ordered phase, a key role of octupole degree of freedom has been focused. In fact, the octupole ordering has been strongly suggested by $^{17}$O-NMR experiments and also by inelastic neutron scattering study. As for the microscopic origin of such higher-order multipole ordering, it has been shown that octupole order is stabilized by the orbital-dependent superexchange interaction, obtained by the second-order perturbation of $5f$ electron hopping in the $\Gamma_8$ degenerate Hubbard model on a fcc lattice. Recently, significant contribution of dotriacontapole moment has been also pointed out.

Since the multipole moments originate from $5f$ electrons, it seems to be natural to consider the Hubbard-like model of $5f$ electrons. However, from the crystal structure of actinide dioxides, it is also important to include explicitly $2p$ electrons, since actinide ion is surrounded by eight oxygens and the main hopping process between nearest neighbor sites should occur from the $f$-$p$ hybridization. In this sense, $f$-$p$ model is more realistic Hamiltonian for actinide dioxides. In fact, the $f$-$p$ model for actinide dioxides has been analyzed in the fourth-order perturbation theory in terms of $f$-$p$ hybridization. Then, it has been revealed that octupole order actually occurs even when we include oxygen $2p$ electrons. However, there has been a peculiar point that the octupole phase appears only for the small absolute value of $(fp\pi)/(fp\sigma)$, where $(fp\sigma)$ and $(fp\pi)$ are Slater-Koster integrals between $f$ and $p$ orbitals. The reason of the sensitivity of the octupole ordered phase concerning the $f$-$p$ hybridization has not been understood yet.

In order to clarify the role of $f$-$p$ hybridization for the appearance of octupole ordering, Maehira and Hotta have performed the band-structure calculations for actinide dioxides by a relativistic linear augmented-plane-wave method with the exchange-correlation potential in a local density approximation. It has been found that the energy bands in the vicinity of the Fermi level are mainly due to the hybridization between actinide $5f$ and oxygen $2p$ electrons. It has been also pointed out that the electronic structure at the $\Gamma$ point in the first Brillouin zone is not consistent with that of the local CEF state. One reason for this inconsistency is that the CEF potentials are not satisfactorily included in the calculations, but it is difficult to control the magnitudes of CEF potential and $f$-$p$ hybridization in the band-structure calculations. It is highly requested to reveal the role of $f$-$p$ hybridization for the simultaneous explanation of the octupole ordering and the local CEF states.
In this paper, in order to clarify the roles of hybridization between actinide 5\(f\) and oxygen 2\(p\) electrons for the electronic structure of actinide dioxides, we analyze the tight-binding \(f-p\) model in detail. Except for the Slater-Koster integrals of \((f p\pi)\) and \((f p\sigma)\), we determine the parameters in the model from the comparison with experimental results and band-structure calculations. In order to reproduce the result of the relativistic band-structure calculations and obtain the electronic structure consistent with the local CEF state, we find that the Slater-Koster parameters for \(f-p\) hybridization should be limited in a certain range. A typical result is found for \((f p\pi) \approx 0\) and \((f p\sigma) \approx 1\) eV, which is consistent with the condition for the appearance of the octupole ordering.

The organization of this paper is as follows. In Sec. II, in order to make this paper self-contained, we briefly review the relativistic band-structure calculations for actinide dioxides. It is meaningful to define the problems included in the band-structure calculations. In Sec. III, we explain a way to construct the \(f-p\) model in the tight-binding approximation. Then, we determine the parameters of the model, except for \((f p\sigma)\) and \((f p\pi)\), from the comparison with the experimental and band-structure calculation results. In Sec. IV, we depict the energy band structure of the \(f-p\) model by changing the values of \(f-p\) hybridization. We deduce the reasonable regions for \((f p\sigma)\) and \((f p\pi)\). In Sec. V, we discuss some future problems concerning the electronic structure of actinide dioxides. Finally, we summarize this paper. Throughout this paper, we use such units as \(\hbar=\kappa_B=1\).

II. BRIEF REVIEW OF BAND-STRUCTURE CALCULATIONS FOR ACTINIDE DIOXIDES

Let us briefly review the band-structure calculation results in order to clarify the problem in the understanding of electronic structure of actinide dioxides. As for details, readers should consult Ref. [2].

We have performed the calculations by using the relativistic linear augmented-plane-wave (RLAPW) method. We assume that all 5\(f\) electrons are itinerant and perform the calculations in the paramagnetic phase. Note that we should take into account relativity even in the calculations for solid state physics because of large atomic numbers of the constituent atoms. The spatial shape of the one-electron potential is determined in the muffin-tin approximation. We use the exchange and correlation potential in a local density approximation (LDA). The self-consistent calculation is carried out for the experimental lattice constant for actinide dioxides.

In Fig. 1, we show a typical result for NpO\(_2\) along the symmetry axes in the Brillouin zone. In the energy band structure in the vicinity of \(E_F\), there always occurs a hybridization between actinide 5\(f\) and oxygen 2\(p\) states for actinide dioxides. The lowest six bands originate from the oxygen 2\(p\) states and are fully occupied and the width of oxygen 2\(p\) band is about 4.76 eV. Narrow bands lying in the region 4.5-7.5 eV are the 5\(f\) bands which are split into two subbands by the spin-orbit interaction. The spin-orbit splitting in the 5\(f\) states is estimated as 0.95 eV, which is consistent with that for isolated neutral Np atom. Note that in the LDA calculation, we find the metallic state for NpO\(_2\), not the insulating state. This point will be discussed later.

Here we remark that \(\Gamma_7\) doublet and \(\Gamma_8\) quartet levels appear around \(E_F\) at the \(\Gamma\) point. It should be noted that the \(\Gamma_7\) level is lower than the \(\Gamma_8\) in our band-structure calculations. However, from the CEF analysis on the basis of the \(j-j\) coupling scheme, \(\Gamma_8\) becomes lower than \(\Gamma_7\) in actinide dioxides. When we accommodate 5\(f\) electrons in \(\Gamma_8\) orbitals, we obtain \(\Gamma_5\) triplet for \(n=2\), \(\Gamma_8\) quartet for \(n=3\), and \(\Gamma_1\) singlet for \(n=4\), as experimentally found in the CEF ground states of UO\(_2\)\(_{22}\), NpO\(_2\)\(_{22}\), and PuO\(_2\)\(_{23,24}\). Note here that \(n\) denotes the number of local 5\(f\) electrons.

In order to resolve the problems, it is necessary to improve the method to include the effect of CEF potentials beyond the simple estimation of the Madelung potential energy. However, it is a difficult task to perform such improvement concerning the formulation of the band-structure calculation. Thus, in this paper, we choose an alternative method to exploit the tight-binding \(f-p\) model for the purpose to understand the role of \(f-p\) hybridization for the change of CEF states in the tight-binding model. By changing the parameters in the \(f-p\) model, we attempt to clarify the key quantities which characterize the electronic structure of actinide dioxides.
III. TIGHT-BINDING APPROXIMATION

A. Crystal structure and unit cell

Before proceeding to the construction of a tight-binding model for actinide dioxides with the fluorite structure, first let us define the unit cell including one actinide ion and two oxygen ions, as shown in the Fig. 2. The basis vectors of the fcc lattice are given by \( \mathbf{a}_1 = (a/2, a/2, 0), \mathbf{a}_2 = (0, a/2, a/2), \) and \( \mathbf{a}_3 = (a/2, 0, a/2), \) where \( a \) is the lattice constant. Thus, in Fig. 2, positions of adjacent four actinide ions are given by \( \mathbf{i}, \mathbf{i} + \mathbf{a}_1, \mathbf{i} + \mathbf{a}_2, \) and \( \mathbf{i} + \mathbf{a}_3, \) where \( \mathbf{i} \) denotes the position vector for one actinide ion.

The positions of eight nearest-neighbor oxygen ions are given by \( \mathbf{b}_1 = (a/4, a/4, a/4), \mathbf{b}_2 = (-a/4, a/4, a/4), \mathbf{b}_3 = (a/4, -a/4, a/4), \mathbf{b}_4 = (-a/4, -a/4, a/4), \mathbf{b}_5 = (-a/4, -a/4, -a/4), \mathbf{b}_6 = (-a/4, a/4, -a/4), \mathbf{b}_7 = (a/4, -a/4, -a/4), \) and \( \mathbf{b}_8 = (a/4, a/4, -a/4). \) Note that the two oxygens, O1 and O2, in the same unit cell are specified by \( \mathbf{b}_1 \) for O1 and \( \mathbf{b}_5 \) for O2, respectively.

B. CEF state

Now we define the basis of \( f \) electrons when we consider the electronic model for actinide dioxides with the fluorite structure. For the purpose, we solve the problem of one \( f \) electron in the CEF potential. The CEF Hamiltonian is written as

\[
H_{\text{CEF}} = \sum_{i,m,m',\sigma} B_{m,m'} f_{i m \sigma}^\dagger f_{i m \sigma}, \tag{1}
\]

where \( f_{i m \sigma} \) is the annihilation operator of \( f \) electron at site \( i \) with spin \( \sigma \) in the orbital specified by \( m \). Note that \( m \) is the \( z \)-component of angular momentum \( \ell = 3 \). We note also that the spin-orbit coupling is not included at this stage.

Since the fluorite structure belongs to \( O_h \) point group, \( B_{m,m'} \) is given by using a couple of CEF parameters \( B_{4}^0 \) and \( B_{6}^0 \) for angular momentum \( \ell = 3 \),

\[
\begin{align*}
B_{3,3} &= B_{-3,-3} = 180B_{4}^0 + 180B_{6}^0 \\
B_{2,2} &= B_{-2,-2} = -420B_{4}^0 - 1080B_{6}^0 \\
B_{1,1} &= B_{-1,-1} = 60B_{4}^0 + 2700B_{6}^0 \\
B_{0,0} &= 360B_{4}^0 - 3600B_{6}^0 \\
B_{3,-1} &= B_{-3,1} = 60\sqrt{15}(B_{4}^0 - 21B_{6}^0) \\
B_{2,-2} &= 300B_{4}^0 + 7560B_{6}^0.
\end{align*}
\]

Note the relation of \( B_{m,m'} = B_{m',m} \).

After performing the diagonalization of \( H_{\text{CEF}} \), we obtain three kinds of CEF states: \( \Gamma_2 \) singlet \((xyz)\), \( \Gamma_4 \) triplet \((x(5x^2 - 3y^2), y(5y^2 - 3z^2), z(5z^2 - 3x^2))\), and \( \Gamma_5 \) triplet \((x(y^2 - z^2), y(x^2 - z^2), z(x^2 - y^2))\). The corresponding CEF energies are given by \( E(\Gamma_2) = -720(B_{4}^0 + 12B_{6}^0) \), \( E(\Gamma_4) = 360(B_{4}^0 - 10B_{6}^0) \), and \( E(\Gamma_5) = -120(B_{4}^0 - 54B_{6}^0) \). Note that these seven states are elements of cubic harmonics for \( \ell = 3 \). In the traditional notation, we express CEF parameters \( B_{4}^0 \) and \( B_{6}^0 \) as \( B_{4}^0 = W x/F(4) \) and \( B_{6}^0 = W(1 - |x|)/F(6) \) with \( F(4) = 15 \) and \( F(6) = 180 \) for angular momentum \( \ell = 3 \).

Note that \( x \) specifies the CEF scheme for \( O_h \) point group, while \( W \) determines an energy scale for the CEF potential.

\[
\begin{align*}
E(\Gamma_2) &= -48W[x + (1 - |x|)], \\
E(\Gamma_4) &= 4W[6x - 5(1 - |x|)], \\
E(\Gamma_5) &= -4W[2x - 9(1 - |x|)].
\end{align*}
\]

The value of \( W \) and \( x \) will be discussed later.

Since we will construct the model in the cubic system, it seems to be natural to use these cubic harmonics as \( f \)-electron basis function. Thus, in the following, we define \( \mu \) as the index to distinguish the orbitals of cubic harmonics. Note that \( \mu \) takes \( 1 \sim 7 \) and the definitions are as follows: 1: \( xyz \), 2: \( x(5x^2 - 3y^2) \), 3: \( y(5y^2 - 3z^2) \), 4: \( z(5z^2 - 3x^2) \), 5: \( x(y^2 - z^2) \), 6: \( y(x^2 - z^2) \), and 7: \( z(x^2 - y^2) \). The corresponding energy \( E_\mu \) is given by the above equations.

C. Hamiltonian

The Hamiltonian is given by

\[
H = H_f + H_{fp} + H_p, \tag{4}
\]

where \( H_f \) and \( H_p \) denote \( f \)- and \( p \)-electron part, respectively, while \( H_{fp} \) indicates \( f-p \) hybridization term. In the following, we explain the construction of each term.
1. f-electron term

The f-electron part is given by

\[ H_f = \sum_{k_\mu, \mu', \sigma} \left[ \varepsilon_{f k_{\mu \mu'}}^{f} + (E_f + E_\mu) \delta_{\mu \mu'} \right] f_{k_{\mu \sigma}}^\dagger f_{k_{\mu' \sigma}} + \lambda \sum_{k_\mu, \mu', \sigma, \sigma'} \zeta_{\mu, \sigma, \mu', \sigma'} f_{k_{\mu \sigma}}^\dagger f_{k_{\mu' \sigma'}}, \quad (5) \]

where \( f_{k_{\mu \sigma}} \) is the annihilation operator of f electron with spin \( \sigma \) in the orbital \( \mu \), \( \varepsilon_{f k_{\mu \mu'}}^{f} \) is the f-electron dispersion due to the hopping between nearest neighbor actinide ions, \( E_f \) is the f-electron level, \( E_\mu \) denotes the CEF potential energy of \( \mu \) orbital, \( \lambda \) is the spin-orbit interaction, and \( \zeta \) is the spin-orbit matrix element.

Concerning the expression of the spin-orbit coupling, it is necessary to step back to the basis of the spherical harmonics. On the basis labelled by \( m \), the spin-orbit interaction \( \zeta_{m, \sigma, m', \sigma'} \) is expressed as

\[ \zeta_{m, \pm 1/2, m, \pm 1/2} = \pm m/2, \]
\[ \zeta_{m, \pm 1/2, \mp 1/2, m, \pm 1/2} = \sqrt{12 - m(m \pm 1)/2}, \quad (6) \]

and zero for the other cases. By transforming the basis from \( m \) to \( \mu \), we obtain \( \zeta_{\mu, \sigma, \mu', \sigma'} \) in eq. (5).

The f-electron dispersion in eq. (5) is expressed as

\[ \varepsilon_{f k_{\mu \mu'}}^{f} = \sum_{\alpha} e^{i k \cdot a} t_{f f}^{f}(\alpha), \quad (7) \]

where \( a \) denotes the vectors connecting twelve nearest neighbor sites of the fcc lattice and \( t_{f f}^{f}(\alpha) \) indicates the f-electron hopping amplitude between \( \mu \) and \( \mu' \) orbitals along the direction of \( a \). Here we note that \( a \) runs among \( \pm a_1, \pm a_2, \pm a_3, \pm (a_2 - a_3), \pm (a_3 - a_1), \) and \( \pm (a_1 - a_2) \). The hopping integral \( t_{f f}^{f}(\alpha) \) is expressed by using the Slater-Koster tables.\(^{27,28}\) Here we consider only the f-electron hopping through \( \sigma \) bond (ff\( \sigma \)).

2. f-p hybridization term

The f-p hybridization term is written as

\[ H_{fp} = \sum_{k_\mu, \mu, \sigma} \sum_{j=1,2} [V_{f k_{\mu \sigma}}^{(j)} f_{f}^j f_{p j k_{\mu \sigma}} + \text{h.c.}], \quad (8) \]

where \( p_{j k_{\mu \sigma}} \) is the annihilation operator of p electron with spin \( \sigma \) in the orbital \( \nu \) of \( j \)-th oxygen and \( j \) denotes the label of oxygen ions in the unit cell, as shown in Fig.1. Note that \( \nu \) runs among \( x, y, \) and \( z \) which correspond to \( p_x, p_y, \) and \( p_z \) orbitals, respectively. The hybridizations \( V^{(1)} \) and \( V^{(2)} \) are, respectively, written as

\[ V_{k_{\mu \sigma}}^{f(1)} = t_{fp}^{f}(b_1) + t_{fp}^{f}(b_4) e^{-i k \cdot a_1} + t_{fp}^{f}(b_4) e^{-i k \cdot a_2} + t_{fp}^{f}(b_6) e^{-i k \cdot a_3} \]
\[ + t_{fp}^{f}(b_3) e^{i k \cdot a_2} + t_{fp}^{f}(b_2) e^{i k \cdot a_3} \quad \text{and} \]

\[ V_{k_{\mu \sigma}}^{f(2)} = t_{fp}^{f}(b_5) + t_{fp}^{f}(b_4) e^{i k \cdot a_1} + t_{fp}^{f}(b_3) e^{i k \cdot a_2} + t_{fp}^{f}(b_2) e^{i k \cdot a_3} \quad (10) \]

where \( t_{fp}^{f}(b) \) denotes the hopping amplitude between \( f \) and \( p \) orbitals along \( b \) direction. Here we note that \( b \) runs among \( b_1 \sim b_8 \). The hopping integral \( t_{fp}^{f}(b) \) is represented in terms of \( (fp\sigma) \) and \( (fp\pi) \) by using the Slater-Koster tables.\(^{27,28}\)

3. p-electron term

The p-electron part is expressed as

\[ H_p = \sum_{k_\mu, \nu, \nu', \sigma} \sum_{i,j} [\varepsilon_{k_{\nu' \nu}}^{(ij)} + E_p \delta_{ij} \delta_{\nu \nu'}] p_{i k_{\nu' \nu}}^\dagger p_{j k_{\nu' \nu}} + \text{h.c.}, \quad (11) \]

where \( \varepsilon_{k_{\nu' \nu}}^{(ij)} \) is the p-electron dispersion, \( i \) and \( j \) denote the label of oxygen ions in the unit cell, as shown in Fig.1, and \( E_p \) is the p-electron level. Note that we take into account nearest neighbor and next nearest neighbor hoppings for p electrons. We also note that the relations of \( \varepsilon_{k_{\nu' \nu}}^{(ij)} = \varepsilon_{k_{\nu' \nu}}^{(ij)} \) and \( \varepsilon_{k_{\nu' \nu}}^{(ij)} = \varepsilon_{k_{\nu' \nu}}^{(ij)} \).

The diagonal part is given by

\[ \varepsilon_{k_{\nu' \nu}}^{(11)} = 2 t_{\nu\nu'}(a_3) \cos(k_x/2 + k_y/2) + 2 t_{\nu\nu'}(a_2 - a_3) \cos(k_x/2 - k_y/2) + 2 t_{\nu\nu'}(a_2) \cos(k_y/2 + k_z/2) + 2 t_{\nu\nu'}(a_3 - a_1) \cos(k_y/2 - k_z/2) + 2 t_{\nu\nu'}(a_3) \cos(k_z/2 + k_x/2) + 2 t_{\nu\nu'}(a_1 - a_2) \cos(k_z/2 - k_x/2), \quad (12) \]

where the hopping amplitudes are given by

\[ t_{\nu\nu'}(a_1) = \begin{pmatrix} p_+ & p_- & 0 \\ p_- & p_+ & 0 \\ 0 & 0 & \langle p\pi \rangle' \end{pmatrix}, \]
\[ t_{\nu\nu'}(a_2 - a_3) = \begin{pmatrix} p_+ & -p_- & 0 \\ -p_+ & p_- & 0 \\ 0 & 0 & \langle p\pi \rangle' \end{pmatrix}, \]
\[ t_{\nu\nu'}(a_2) = \begin{pmatrix} \langle p\pi \rangle' & 0 & 0 \\ 0 & p_+ & p_- \\ 0 & p_- & p_+ \end{pmatrix}, \]
\[ t_{\nu\nu'}(a_3 - a_1) = \begin{pmatrix} \langle p\pi \rangle' & 0 & 0 \\ 0 & p_+ & p_- \\ 0 & p_- & p_+ \end{pmatrix}, \]
\[ t_{\nu\nu'}(a_3) = \begin{pmatrix} p_+ & 0 & p_- \\ 0 & \langle p\pi \rangle' & 0 \\ p_- & 0 & p_+ \end{pmatrix}, \]
\[ t_{\nu\nu'}(a_1 - a_2) = \begin{pmatrix} p_+ & 0 & p_- \\ 0 & \langle p\pi \rangle' & 0 \\ -p_- & 0 & p_+ \end{pmatrix}. \quad (13) \]
Here \( p_\pm = [(p\sigma)']^2 [p\pi']^2 /2 \), where \( (p\sigma)' \) and \( (p\pi)' \) denote the Slater-Koster integral of \( p \) electron among next-nearest neighbor oxygen sites.

As for the off-diagonal parts, we obtain

\[
\begin{align*}
\xi_{kxx}^{(12)} &= (p\sigma)[e^{i(k-a_1+a_2)} + e^{i(k-a_2)}] \\
&+ (p\pi)[e^{i(k-a_1+a_2)} + e^{i(k-a_2)}] \\
&+ (p\pi)[e^{i(k-a_2+a_3)} + e^{i(k-a_1)}],
\end{align*}
\]

and

\[
\begin{align*}
\xi_{kyy}^{(12)} &= (p\sigma)[e^{i(k-a_1+a_2)} + e^{i(k-a_2)}] \\
&+ (p\pi)[e^{i(k-a_1+a_2)} + e^{i(k-a_2)}] \\
&+ (p\pi)[e^{i(k-a_2+a_3)} + e^{i(k-a_1)}],
\end{align*}
\]

and

\[
\begin{align*}
\xi_{kzz}^{(12)} &= (p\sigma)[e^{i(k-a_1+a_2)} + e^{i(k-a_2)}] \\
&+ (p\pi)[e^{i(k-a_1+a_2)} + e^{i(k-a_2)}] \\
&+ (p\pi)[e^{i(k-a_2+a_3)} + e^{i(k-a_1)}].
\end{align*}
\]

Other off-diagonal components are all zeros.

### D. Parameters of the model

The tight-binding Hamiltonian includes many parameters. Here we try to fix some of them from the experimental and band-structure calculation results.

(i) CEF parameters. It should be noted that it is possible to reproduce the CEF states of actinide dioxide, when we accommodate plural numbers of \( f \) electrons in the level scheme in which \( \Gamma_8 \) is lower than \( \Gamma_7 \). As already mentioned in Sec. II, we obtain \( \Gamma_5 \) triplet for \( n=2 \), \( \Gamma_6 \) quartet for \( n=3 \), and \( \Gamma_7 \) singlet for \( n=4 \), as experimentally found in the CEF ground states of \( \text{UO}_2^{22} \), \( \text{NpO}_2 \), and \( \text{PuO}_2^{23,24} \). Thus, in the present tight-binding model, we set \( W = -0.01 \text{ eV} \) and \( z = 0.7 \) in order to reproduce that \( \Gamma_5 \) quartet is the ground state and \( \Gamma_7 \) is the excited state with the excitation energy of about 0.2 eV.

(ii) Spin-orbit coupling. From the relativistic band-structure calculation for actinide atom, the splitting energy between \( j=5/2 \) and \( j=7/2 \) has been found to be about 1 eV. Since the splitting energy is given as \( (7/2)\lambda \) with the use of spin-orbit coupling \( \lambda \), we fix it as \( \lambda = 0.3 \text{ eV} \).

(iii) \( f \) - and \( p \)-electron levels. In this paper, the \( f \)-electron level \( E_f \) is set as the origin of energy, leading to \( E_f = 0 \). On the other hand, the \( p \)-electron level \( E_p \) is considered to be \( E_p = -4 \text{ eV} \) from the comparison of the relativistic band-structure calculation results.\(^{21}\)

(iv) Slater-Koster integrals. In the model, we use seven Slater-Koster integrals as \( (ff\sigma), (fp\sigma), (fp\pi), (pp\sigma), (pp\pi), (pp\sigma)' \), and \( (pp\pi)' \). Among them, concerning the \( p \)-electron hoppings, we introduce the ratio \( \eta \) between nearest and next nearest neighbor hopping amplitudes, given by \( \eta = (pp\sigma)/(pp\sigma)' = (pp\pi)/(pp\pi)' \). From the ratio of the distances of nearest and next nearest neighbor oxygen sites, we set \( \eta = (1/\sqrt{2})^{7/2} \approx 0.3 \). As for \( (pp\sigma) \) and \( (pp\pi) \), we determine them as \( (pp\sigma)=0.4 \text{ eV} \) and \( (pp\pi)=-0.4 \text{ eV} \), after several trials to reproduce the structure of the wide \( p \) bands in the relativistic band structure calculations.

Concerning \( (ff\sigma) \), it is related with the bandwidth \( W \) of \( f \) electrons in the \( j=5/2 \) states on the fcc lattice. In the limit of infinite \( \lambda \), we have obtained \( W \) as \( W = (3/56)(50 + 2\sqrt{145}) (ff\sigma) \approx 4.0 (ff\sigma) \). Note that for the case of finite \( \lambda \), the width of \( j=5/2 \) bands is deviated from \( W \), but when \( \lambda \) is large enough as in actual actinide compounds, the bandwidth is found to be almost equal to \( W \). From the comparison with the relativistic band-structure calculation results, the width of \( j=5/2 \) bands is 0.5–0.7 eV, suggesting that \( (ff\sigma) \) is in the order of 0.1 eV. Then, we set \( (ff\sigma)=0.1 \text{ eV} \) in the present model.

In the following calculations, due to the diagonalization of the Hamiltonian, we depict the tight-binding bands of \( (fp\sigma) \) and \( (fp\pi) \), which are believed to be key parameters to understand the electronic structure of actinide dioxide.

### IV. RESULTS

Now we show our results of the diagonalization of the tight-binding model. Note that in the following figures of the band structure, “0” in the vertical axis indicates the origin of the energy, not the Fermi level \( E_F \). If it is necessary to draw the line of \( E_F \), we set it from the condition of \( \langle n \rangle = 3 \) for tetravalent Np ion in NpO\(_2\), where \( \langle n \rangle \) denotes the average number of \( f \) electrons per actinide ion. In the present paper, we do not take care of the difference in actinide ions.

First, we consider the case in which the \( f-p \) hybridization is simply suppressed. In Fig. 3(a), we show the tight-binding bands for \( (fp\sigma)=0 \) along the lines in the first Brillouin zone. We obtain the \( f \) and \( p \) bands which are not hybridized with each other and \( f \) bands split into \( j=5/2 \) and \( j=7/2 \). Note that \( \Gamma_8 \) becomes lower than \( \Gamma_7 \) at the \( \Gamma \) point due to the effect of local CEF potentials. We observe some degeneracy in \( p \) bands which will be lifted by \( f-p \) hybridization.

In our first impression, in spite of the simple suppression of the \( f-p \) hybridization, the overall structure of \( f \) and \( p \) bands seems to be similar to that of the relativistic band-structure calculations in Fig. 1. However, some significant difference is found in the \( p \)-band structure. For instance, we find the level crossing in the \( p \)-band structure of Fig. 3(a) between the \( \Gamma \) and \( \Gamma \) points, but we do not observe such behavior in Fig. 1. Such difference originates from the simplification to consider only actinide 5f and oxygen 2p electrons. The difference in the \( p \)-band structure is not further discussed in this paper.

Next we include the \( f-p \) hybridization as \( (fp\sigma)=1 \text{ eV} \) and \( (fp\pi)=0.1 \text{ eV} \) in Fig. 3(b). Due to the effect of \( f-p \) hybridization, we find additional dispersion in \( f \) and \( p \)
bands. In particular, the $p$-band structure becomes similar to that in the relativistic band-structure calculations. In this case, we still observe that $\Gamma_8$ is lower than $\Gamma_7$ at the $\Gamma$ point.

Let us now consider the cases of negative $(fp\pi)$ by keeping the value of $(fp\sigma)=1\text{ eV}$. In Figs. 4(a) and 4(b), we show the results for $(fp\pi)=-0.1\text{ eV}$ and $-0.6\text{ eV}$, respectively. For $(fp\pi)=-0.1\text{ eV}$, we do not find significant difference in the band structure from the case of $(fp\pi)=0.1\text{ eV}$. However, for $(fp\pi)=-0.6\text{ eV}$, we find that $\Gamma_7$ is lower than $\Gamma_8$ at the $\Gamma$ point. Regarding the CEF states at the $\Gamma$ point, the $f$-$p$ model with $(fp\sigma)=1\text{ eV}$ and $(fp\pi)=-0.6\text{ eV}$ seems to reproduce the relativistic band-structure calculation results. Note that in the $p$-band structure, we find the level crossing of two low-energy bands along the line between $W$ and $L$ points, which has not been observed in the band-structure calculation. However, as mentioned above, we do not further pursue the difference in the $p$-band structure.

Here we turn our attention to the $f$-electron states at the $\Gamma$ point. In the relativistic band-structure calculations for $\text{NpO}_2$, we have already pointed out that the $\Gamma_7$ level becomes lower than that of $\Gamma_8$, in sharp contrast to the local CEF state in the $j-j$ coupling scheme expected from the experimental results. This is due to the fact that the CEF potential is not included satisfactorily in the relativistic band-structure calculation. On the other hand, the CEF potential is included in the tight-binding model within the point charge approximation and the change of the level scheme at the $\Gamma$ point can be explained by the $f$-$p$ hybridization. When we do
FIG. 5: Energy difference $\Delta$ between $\Gamma_7$ and $\Gamma_8$ states at the $\Gamma$ point in the $j=5/2$ bands as a function of $(f_p\pi)$ for $(f_p\sigma)=0$ eV (solid curve), $(f_p\pi)=1$ eV (broken curve), and $(f_p\pi)=-1$ eV (dotted curve). A positive $\Delta$ denotes that the energy of $\Gamma_7$ is larger than that of $\Gamma_8$.

not consider the $f$-$p$ hybridization, we find that $\Gamma_8$ level becomes lower than that of $\Gamma_7$, but with the increase of the effect of $f$-$p$ hybridization, the order of the level at the $\Gamma$ point is converted. Namely, the order of $\Gamma_7$ and $\Gamma_8$ levels is determined by the competition between the CEF potential and the $f$-$p$ hybridization. In this sense, the CEF potential is not included satisfactorily in comparison with the $f$-$p$ hybridization in the band-structure calculation.

In the fluorite crystal structure of AnO$_2$, actinide ion is surrounded by eight oxygen ions in the [111] and other equivalent directions. Thus, the $\Gamma_7$ orbital is penalized from the viewpoint of electrostatic energy, since its wavefunction is elongated along the [111] directions. However, the wavefunctions of two $\Gamma_8$ orbitals are expanded in the directions of axes. Namely, it is qualitatively understood that $\Gamma_8$ level is lower than $\Gamma_7$ one in the actinide dioxides.

From the viewpoint of the overlap integral between actinide 5$f$ and oxygen 2$p$ electrons, we expect that the hybridization of $\Gamma_7$ orbital is larger than that of $\Gamma_8$. Thus, due to the effect of $f$-$p$ hybridization, the $\Gamma_7$ level becomes lower than $\Gamma_8$, even if the local CEF ground state is $\Gamma_8$. When the effect of $f$-$p$ hybridization is relatively larger than that of the CEF potential, it is possible to observe that $\Gamma_7$ is lower than $\Gamma_8$, as actually found in the relativistic band-structure calculation results. We emphasize that it is one of the key points concerning the $f$-$p$ hybridization to understand the electronic structure of actinide dioxides.

In Fig. 5, we depict the energy difference $\Delta$ between the $\Gamma_8$ and $\Gamma_7$ states at the $\Gamma$ point as functions of $(f_p\pi)$ for several values of $(f_p\sigma)$. Note that $\Delta$ is positive when $\Gamma_8$ is lower than $\Gamma_7$. For $(f_p\sigma)=0$, we find that $\Delta$ is positive in the region of $|\langle f_p\pi \rangle|<1.2$ eV. When we change the value of $(f_p\sigma)$, $\Delta$ is found to be maximum at $(f_p\pi)=-(f_p\sigma)$ due to the effective disappearance of the $f$-$p$ hybridization between actinide $\Gamma_7$ and oxygen 2$p$ electrons.

Readers may consider that the absolute value of $(f_p\pi)$ should not be so small only for the purpose to keep the order of the local CEF states. However, if we increase the absolute value of $(f_p\pi)$ for $(f_p\sigma)=1$ eV, we should remark that the $f$- and $p$-electron bands are significantly changed from those in the relativistic band-structure calculation results. Thus, from the viewpoints of the local CEF states and the comparison with the band-structure calculations, the reasonable parameters are found in the case of small $|\langle f_p\pi \rangle|$ for $(f_p\sigma)=1$ eV.

V. DISCUSSION AND SUMMARY

In this paper, we have analyzed the tight-binding model for AnO$_2$ in comparison with the local CEF states and the result of the relativistic band-structure calculations. We have concluded that $|\langle f_p\pi \rangle|$ should be small for the case of $(f_p\sigma)=1$ eV in our tight-binding model in order to keep the CEF levels at the $\Gamma$ point. We have also emphasized that such a condition coincides with that for the octupole ordering on the basis of the $f$-$p$ model. Namely, the condition to keep the local $\Gamma_8$ ground state is consistent with the appearance of the ordering of magnetic octupole which is composed of complex spin and orbital degrees of freedom.

Here we provide a comment on the local CEF state in the band-structure calculations. As long as we perform the band-structure calculations with in the LDA, it is found that the $\Gamma_7$ state becomes lower than the $\Gamma_8$ at the $\Gamma$ point, in contrast to the local CEF state expected from the experiment. In this paper, we have proposed the scenario to control the effect of $f$-$p$ hybridization on the CEF state, but it should be remarked that in the LDA calculation, we could not obtain insulating state corresponding to the multipole ordering for NpO$_2$. In order to improve this point, we need to consider the effect of the Coulomb interactions, but it is a serious problem. One way for this problem is to employ the LDA+$U$ method. In fact, it has been reported that we observed state with octupole and higher multipoles can be reproduced, suggesting that the $\Gamma_8$ state is lower than $\Gamma_7$ in the electronic structure. The effective inclusion of the Coulomb interaction is an alternative scenario to understand the CEF state consistent with the experiments.

Although we have not discussed the difference in electronic structure due to the change of actinide ions in this paper, it is naively expected that the difference between $E_f$ and $E_p$ becomes small in the order of Th, U, Np, Pu, Am, and Cm from the chemical trends in actinide ions and the previous band-structure calculations. On the other hand, the change of $f$-$p$ hybridization among actinide dioxides may play more important role to explain the effect of the difference in actinide ions. It is an interesting future problem to clarify the key issue to understand the difference in electronic structure of actinide
In summary, we have constructed the $f$-$p$ model in the tight-binding approximation. We have determined the parameters by the experimental results and the relativistic band-structure calculations. It has been concluded that the absolute value of $|fp\pi|$ should be small for $|fp\sigma|=1$ eV in order to reproduce simultaneously the local CEF states and the band-structure calculation results. The small value of $|fp\pi|$ is consistent with the condition to obtain the octupole ordering in the previous analysis of the $f$-$p$ model. We believe that the present tight-binding model will useful to extract the essential point of the electronic structure of actinide dioxides from the complicated band-structure calculation results.
