Introduction

Stenosing tenosynovitis of the flexor hallucis tendon in the region of the sustentaculum tali leading to entrapment and triggering of the great toe is a pathology that is relatively well described within the medical literature. It is most often reported in ballet dancers, sports people or in association with trauma [3,5,10-13]. However, distal entrapment in the region of the tibial sesamoids is a much rarer entity, especially in a young patient with no clear underlying cause [1,2].

Case Report

A 28-year-old Caucasian female patient presented with a three-month history of triggering of the right great toe, associated to joint crepitus. Further examination revealed mild tenderness around the medial malleolus in line with the proximal FHL tendon upon triggering. There was no history of trauma, or participation in sporting activity. Examination of the foot and ankle was otherwise unremarkable, with normal range of movement and no neurovascular deficit present.

Discussion

Stenosing tenosynovitis of the hallux is a relatively well described pathology, and is most commonly described in ballet dancers [3]. By far the most commonly reported site of entrapment is in the region of the sustenaculum tali, posterior to the medial malleolus [3,5,7,8,10]. We were able to find two previous papers describing FHL pathology distally in the sesamoid region. Firstly a paper by Gould et al., presenting nine cases largely associated to a precipitating injury. Three of Gould’s patients were treated by local infiltration of the tendon sheath with 1% lidocaine, the remainder underwent surgery [2]. Local injection of steroid & anesthetic were the treatment of...
choice in our patient, with satisfactory results. A second paper by Sanhudo, J. reported a single case of triggering as a result of tenosynovitis at the sesamoid area following toe trauma. In this paper, the patient did not respond to non-operative management, requiring surgical tenolysis to provide adequate symptomatic relief [1]. We have presented a case of hallux saltans due impediment of the FHL tendon in the region of the tibial sesamoids, with no clear precipitating cause.
