Quasi-pseudo-metrization of topological preordered spaces

E. Minguzzi∗

Abstract

We establish that every second countable completely regularly pre-ordered space is quasi-pseudo-metrizable. In the ordered case it is proved that these spaces can be characterized as being order homeomorphic to subspaces of the ordered Hilbert cube. The connection with quasi-pseudo-metrization results obtained in bitopology is clarified. In particular, strictly quasi-pseudo-metrizable ordered spaces are characterized as being order homeomorphic to order subspaces of the ordered Hilbert cube.

1 Introduction

A fundamental theorem by Urysohn and Tychonoff establishes that every second countable regular space ($T_3$-space) is metrizable. This work aims at generalizing this result for topological spaces endowed with a preorder $\leq$. In this case one would like to prove the existence of a function $p : E \times E \to [0, +\infty)$ which encodes both the topology and the preorder, where the latter is obtained through the condition $x \leq y$ iff $p(x, y) = 0$. Clearly, function $p$ cannot be a metric in the usual sense, in fact we shall need the more general notion of quasi-pseudo-metric.

Topological preordered spaces appear in various fields, for instance in the study of dynamical systems [1], general relativity [2], microeconomics [3] and computer science [4]. Quasi-pseudo-metrizable preordered spaces are among the most well behaved topological preordered spaces, thus it is important to establish if one can just work with quasi-pseudo-metrizable preordered spaces in the mentioned applications. Topological preordered spaces are connected to bitopological spaces but the latter spaces are less directly connected with the said applications. This is so because, generically, a flow on a manifold, a causal order on spacetime, or a preference of an agent in microeconomics, to make a few examples, are represented by a preorder which does not necessarily come from a nicely behaved bitopological space. The category of topological preordered spaces is in this respect more interesting, and so far much less investigated, than that of bitopological spaces.

Some definitions will help us to make our mathematical problem more precise. A topological preorderedspace is a triple \((E, \mathcal{F}, \leq)\) where \((E, \mathcal{F})\) is a topological space and \(\leq\) is a preorder, namely a reflexive and transitive relation. Our terminology for topological preorderedspace will follow Nachbin [5].

Two topological preorderedspace \(E_1, E_2\), are preorder homeomorphic if there is an homeomorphism \(\varphi : E_1 \to E_2\) such that \(x \leq y\) if and only if \(\varphi(x) \leq \varphi(y)\). A subset \(S \subset E\) of a topological preorderedspace \(E\) is a subspace once it is endowed with the induced topology \(\mathcal{F}_S\) and preorder \(\leq_S\) defined by: for \(x, y \in S\), \(x \leq_S y\) if \(x \leq y\). The topological preorderedspace \(E_1\) is preorder embedded in \(E_2\) if it is preorder homeomorphic with a subspace of \(E_2\).

A preorder is an order if it is antisymmetric. With \(i(x) = \{y : x \leq y\}\) and \(d(x) = \{y : y \leq x\}\) we denote the increasing and decreasing hulls. The topological preorderedspace is semiclosed preorderedspace if \(i(x)\) and \(d(x)\) are closed for every \(x \in E\), and it is closed preorderedspace if the graph of the preorder

\[ G(\leq) = \{(x, y) : x \leq y\}, \]

is closed. A subset \(S \subset E\), is called increasing or upper if \(i(S) = S\) and decreasing or lower if \(d(S) = S\). It is called monotone if it is increasing or decreasing. A subset \(C\) is convex if it is the intersection of a decreasing and an increasing set in which case it follows \(C = d(C) \cap i(C)\). In this work it is understood that the set inclusion is reflexive, \(S \subset S\).

The topological preorderedspace is a normally preorderedspace if it is semiclosed preorderedspace and for every closed decreasing set \(A\) and closed increasing set \(B\) which are disjoint, \(A \cap B = \emptyset\), it is possible to find an open decreasing set \(U\) and an open increasing set \(V\) which separate them, namely \(A \subset U, B \subset V\), and \(U \cap V = \emptyset\).

The topological preorderedspace is a regularly preorderedspace if it is semiclosed preorderedspace, \(a)\) for every closed decreasing set \(A\) and closed increasing set \(B\) of the form \(B = i(x)\) which are disjoint, \(A \cap B = \emptyset\), it is possible to find an open decreasing set \(U\) and an open increasing set \(V\) which separate them, namely \(A \subset U, B \subset V\), and \(U \cap V = \emptyset\) and \(b)\) for every closed decreasing set \(A\) of the form \(A = d(x)\) and closed increasing set \(B\) which are disjoint, \(A \cap B = \emptyset\), it is possible to find an open decreasing set \(U\) and an open increasing set \(V\) which separate them, namely \(A \subset U, B \subset V\), and \(U \cap V = \emptyset\).

An isotone function is a function \(f : E \to \mathbb{R}\) such that \(x \leq y \Rightarrow f(x) \leq f(y)\).

In a normally preorderedspace if \(A\) is closed decreasing, \(B\) is closed increasing and \(A \cap B = \emptyset\), there is some continuous isotone function \(f : E \to [0,1]\), such that \(A \subset f^{-1}(0)\) and \(B \subset f^{-1}(1)\) (this is the preorder analog of Urysohn separation lemma, see [3] Theor. 1]). Normally preorderedspace are closed preorderedspace, and closed preorderedspace are semiclosed preorderedspace.

A topological preorderedspace is convex at \(x \in E\), if for every open neighborhood \(O \ni x\), there are an open decreasing set \(U\) and an open increasing set \(V\) such that \(x \in U \cap V \subset O\). The topological preorderedspace \(E\) is convex if it is convex at every point [3] [6] [7]. Notice that according to this terminology the statement “the topological preorderedspace \(E\) is convex” differs from the statement “the subset \(E\) is convex” (which is always true). The terminology is not
uniform in the literature, for instance Lawson [8] calls strongly order convexity what we call convexity.

A quasi-uniformity [5, 9] is a pair \((X, U)\) such that \(U\) is a filter on \(X \times X\), whose elements contain the diagonal \(\Delta = \{(x, y) : x = y\}\), and such that if \(V \in U\) then there is \(W \subset U\), such that \(W \circ W \subset V\). A quasi-uniformity is a uniformity if \(V \in U\) implies \(V^{-1} \in U\). To any quasi-uniformity \(U\) corresponds a dual quasi-uniformity \(U^{-1} = \{U : U^{-1} \in U\}\).

From a quasi-uniformity \(U\) it is possible to construct a topology \(T(U)\) in such a way that a base for the filter of neighborhoods at \(x\) is given by the sets of the form \(U(x)\) where \(U(x) = \{y : (x, y) \in U\}\) with \(U \in U\). In other words \(O \in T(U)\) if and only if for every \(x \in O\) there is \(U \in U\) such that \(U(x) \subset O\).

Given a quasi-uniformity \(U\) the family \(U^*\) given by the sets of the form \(V \cap W^{-1}\), \(V, W \in U\), is the coarsest uniformity containing \(U\). The symmetric topology of the quasi-uniformity is \(T(U^*)\). Moreover, the intersection \(\bigcap U\) is the graph of a preorder on \(X\) (see [5]), thus given a quasi-uniformity one naturally obtains a topological preordered space \((X, T(U^*), \bigcap U)\). The topology \(T(U^*)\) is Hausdorff if and only if the preorder \(\bigcap U\) is an order [5].

A completely regularly preordered space (Tychonoff-preordered space), is a topological preordered space for which the following two conditions hold:

(i) \(T\) coincides with the initial topology generated by the set of continuous isotone functions \(g : E \to [0, 1]\),

(ii) \(x \preceq y\) if and only if for every continuous isotone function \(f : E \to [0, 1]\), \(f(x) \leq f(y)\).

Convex normally preordered spaces are completely regularly preordered spaces and completely regularly preordered spaces are convex closed preordered spaces [5]. Nachbin proves [5 Prop. 8] that a topological preordered space \((E, T, \preceq)\) comes from a quasi-uniformity \(U\), in the sense that \(T = T(U^*)\) and \(G(\preceq) = \bigcap U\) if and only if it is a completely regularly preordered space, and proves that every Hausdorff quasi-uniformizable space admits a closed order compactification (the Nachbin compactification).

For the discrete preorder \(G(\preceq) = \Delta\), the definitions of normally preordered space, completely regularly preordered space, regularly preordered space, closed preordered space, reduce respectively to normal space, completely regular space, regular space \((T_3\)-space), Hausdorff space.

A bitopological space is a triple \((E, \mathcal{P}, \mathcal{Q})\) where \(E\) is a set and \(\mathcal{P}, \mathcal{Q}\), are two topologies on \(E\). It is possible to associate to every topological preordered space a bitopological space by taking as \(\mathcal{P}\) the topology made of all the upper sets \(\mathcal{T}^u\), and as \(\mathcal{Q}\) the topology made of all the lower sets \(\mathcal{T}^l\). Bitopological spaces were introduced by Kelly [10] and subsequently investigated in [11, 12].

A quasi-pseudo-metric [10, 11] on a set \(X\) is a function \(p : X \times X \to [0, +\infty)\) such that for \(x, y, z \in X\)

(i) \(p(x, x) = 0\),

(ii) \(p(x, z) \leq p(x, y) + p(y, z)\).
The quasi-pseudo-metric is called quasi-metric \[13\] if (i) is replaced with (i'): \(p(x, y) = 0\) if and only if \(x = y\). Other variations exist in the literature. For instance, if (i) is replaced by (i'' ) \(p(x, y) = p(y, x) = 0\) if \(x = y\), we get what is sometimes referred to as Albert’s quasi-metric \[14\].

The quasi-pseudo-metric is called pseudo-metric if \(p(x, y) = p(y, x)\). If a quasi-metric is such that \(p(x, y) = p(y, x)\) then it is a metric in the usual sense. Sometimes quasi-pseudo-metrics are called semi-metrics \[5\] but for other authors semi-metrics are quite different objects \[13\]. If \(p\) is a quasi-pseudo-metric then \(q\), defined by

\[ q(x, y) = p(y, x), \]

is a quasi-pseudo-metric called conjugate of \(p\). This structure, called quasi-pseudo-metric space, is denoted \((X, p, q)\).

From a quasi-pseudo-metric space \((E, p, q)\) we can construct a quasi-uniformity \(U\) and the associated topological preordered space \((E, T(U^*)) (\bigcap U)\) following Nachbin \[5\], or a bitopological space \((X, \mathcal{P}, \mathcal{Q})\) following Kelly \[10\].

Nachbin defines the quasi-uniformity \(U\) as the filter generated by the countable base

\[ W_n = \{(x, y) \in X \times X : p(x, y) < 1/n\}. \]

Thus the graph of the preorder is \(G(\leq) = \bigcap U = \{(x, y) : p(x, y) = 0\}\) and the topology \(T(U^*)\) is that of the pseudo-metric \(p + q\). In particular this topology is Hausdorff if and only if \(p + q\) is a metric i.e. \(p(x, y) + p(y, x) = 0 \Rightarrow x = y\), which is the case if and only if the preorder \(\leq\) is an order. Clearly, every topological preordered space obtained in this way is a completely regularly preordered space as it comes from a quasi-uniformity.

Given a quasi-pseudo-metric \(p\) we shall denote \(P(x, r) = \{y : p(x, y) < r\}\) the \(p\)-ball of radius \(r\) centered at \(x\), and analogously \(Q(x, r) = \{y : q(x, y) < r\}\) will be the \(q\)-ball for the conjugate metric \(q\). If \(d = p + q\), the \(d\)-balls will be denoted \(D(x, r) = \{y : d(x, y) < r\}\).

From a quasi-pseudo-metric space \((E, p, q)\) Kelly constructs a bitopological space \((X, \mathcal{P}, \mathcal{Q})\) as follows: \(\mathcal{P}\) is the topology having as base the sets of the form \(P(x, r)\) for arbitrary \(x \in X\) and \(r > 0\). Analogously, \(\mathcal{Q}\) is the topology having as base the sets of the form \(Q(x, r)\) for arbitrary \(x \in X\) and \(r > 0\).

Remark 1.1. A base of open neighborhoods at \(z \in X\) is given by the sets of the form \(P(z, \epsilon), \epsilon > 0\). Indeed, if \(z \in \{y : p(x, y) < r\}\), that is \(p(x, z) < r\), then there is \(\epsilon\) such that \(\{w : p(z, w) < \epsilon\} \subset \{y : p(x, y) < r\}\). This follows from \(p(x, w) \leq p(x, z) + p(z, w)\), as choosing \(\epsilon = r - p(x, z)\), we get \(p(x, w) < r\).

\section{2 Quasi-pseudo-metrizability and preorders}

We give and motivate the following definitions.

\textbf{Definition 2.1.} 
A topological preordered space \((E, \mathcal{T}, \leq)\) is quasi-pseudo-metrizable if there is a pair of conjugate quasi-pseudo-metrics \(p, q\), said admissible, such that \(\mathcal{T}\) is the...
topology generated by the pseudo-metric \( p + q \), and the graph of the preorder
is given by \( G(\leq) = \{ (x, y) : p(x, y) = 0 \} \).

A topological preordered space \((E, \mathcal{T}, \leq)\) is strictly quasi-pseudo-metrizable if it
is convex semiclosed preordered and there is a pair of conjugate quasi-metrics \( p, q \), such that the topology associated to \( p \) is the upper topology \( \mathcal{T}^a \),
and the topology associated to \( q \) is the lower topology \( \mathcal{T}^b \).

A (strictly) quasi-pseudo-metrizable preordered space is a (strictly) quasi-
pseudo-metrized preordered space if a choice of conjugate metrics complying
with the previous requirement is made.

It must be noted that we call strictly quasi-pseudo-metrizable space what,
taking as reference the literature on bitopological spaces, one would simply call
quasi-pseudo-metrizable space. The point is that in the topological preordered
space version of a topological property one has usually two or more possibilities
and the stronger can often be interpreted as the bitopological version of the
property. For instance, Lawson \([8]\) defines the strictly completely regularly or-
dered spaces which do not admit a bitopological interpretation.

**Proposition 2.2.** Let \((E, \mathcal{T}, \leq)\) be quasi-pseudo-metrizable preordered space
and let \( p, q \) be a pair of admissible conjugate quasi-pseudo metrics. The function
\( p : E \times E \to \mathbb{R} \) is continuous in the product topology \( \mathcal{T} \times \mathcal{T} \) on \( E \). Moreover,
it is Lipschitz with respect to \( d = p + q \), in the sense that
\[
|p(x, y) - p(w, z)| \leq d(x, w) + d(y, z). \tag{2}
\]
For a fixed \( x \in E \), the function \( q(x, \cdot) \) is isotone and the function \( p(x, \cdot) = q(\cdot, x) \)
is anti-isotone.

**Proof.** The repeated application of the triangle inequality gives
\[
\begin{align*}
  p(x, y) &\leq p(x, w) + p(w, z) + p(z, y) \leq d(x, w) + p(w, z) + d(y, z), \\
  p(w, z) &\leq p(w, x) + p(x, y) + p(y, z) \leq d(x, w) + p(x, y) + d(y, z),
\end{align*}
\]
thus \( |p(x, y) - p(w, z)| \leq d(x, w) + d(y, z) \). By assumption, \( d \) generates \( \mathcal{T} \) thus
\( p \) is continuous in the product topology \( \mathcal{T} \times \mathcal{T} \).

If \( y \leq z \) then \( p(y, z) = q(z, y) = 0 \) and \( q(x, y) \leq q(x, z) + q(z, y) = q(x, z) \)
namely \( q(x, \cdot) \) is isotone. If \( y \leq z \) then \( p(y, z) = 0 \) and \( p(x, z) \leq p(x, y) + p(y, z) = p(x, y) \)
namely \( p(x, \cdot) \) is anti-isotone. \( \square \)

**Proposition 2.3.** Every strictly quasi-pseudo-metrizable preordered space is a
quasi-pseudo-metrizable preordered space. Every quasi-pseudo-metrizable pre-
ordered space is a completely regularly preordered space.

**Proof.** Equation \( \tag{2} \) can be obtained as in the proof of Prop \( \tag{2} \) and written
\[
|p(x, y) - p(w, z)| \leq p(x, w) + q(x, w) + p(y, z) + q(y, z),
\]
from which it follows that \( p \) is continuous in the product topology \( \sup(\mathcal{T}^a, \mathcal{T}^b) \times \sup(\mathcal{T}^a, \mathcal{T}^b) \) (and
anallogously for $q$). Thus $p + q$ is sup($\mathcal{T}^\sharp, \mathcal{T}^\flat$)$\times$ sup($\mathcal{T}^\sharp, \mathcal{T}^\flat$)-continuous, which implies that the topology $\mathcal{D}$ of the pseudo-metric $d = p + q$ is coarser than sup($\mathcal{T}^\sharp, \mathcal{T}^\flat$). However, since $p, q \leq d$ the $p$-balls and $q$-balls centered at a point are $\mathcal{D}$-open neighborhoods of the point, thus by remark 1.1 sup($\mathcal{T}^\sharp, \mathcal{T}^\flat$) is coarser than $\mathcal{D}$, thus $\mathcal{D} = \sup(\mathcal{T}^\sharp, \mathcal{T}^\flat)$ which implies $\mathcal{D} = \mathcal{T}$.

Since $(E, \mathcal{T}, \leq)$ is semiclosed preordered, $i(x)$ is closed thus $i(x) = \text{cl}_{\mathcal{T}^\flat} x$. It follows that $y \in i(x)$ iff every $q$-ball centered at $y$ includes $x$ which is equivalent to “for all $n \geq 1$, $x \in \{w : q(y, w) < 1/n\}$,” which in turn is equivalent to $p(x, y) = 0$. We conclude that $y \in i(x)$ iff $p(x, y) = 0$.

For the last statement, every quasi-pseudo-metrizable topological preordered space comes from a quasi-uniformity and hence is a completely regularly preordered space.

The problem of quasi-pseudo-metrization of a bitopological space was considered already in Kelly’s work [10] and has been extensively studied over the years [17, 18, 19, 20, 21, 22, 23, 24]. As we shall see in a moment, the solution to this problem can be used to infer results on the quasi-pseudo-metrizability of a topological preordered space. The quasi-pseudo-metrizability of a topological space has also been investigated [25, 26, 27, 28, 29] but it is less interesting for our purposes because just one topology cannot bring information on a non trivial preorder.

For bitopological spaces Kelly [10, Theor. 2.8] obtained a generalization of Urysohn’s metrization theorem which in our topological preordered space framework reads as follows

**Theorem 2.4.** (Kelly) Let $(E, \mathcal{T}, \leq)$ be a convex regularly preordered space and assume that both $\mathcal{T}^\sharp$ and $\mathcal{T}^\flat$ are second countable, then $(E, \mathcal{T}, \leq)$ is strictly quasi-pseudo-metrizable.

Unfortunately, this theorem is not so easily applied to topological preordered spaces because the second countability of $\mathcal{T}$ does not imply the second countability of the coarser topologies $\mathcal{T}^\sharp$ and $\mathcal{T}^\flat$. This type of difficulty is met for the various quasi-pseudo-metrizability results that can be found in the literature on bitopological spaces. We shall nevertheless show that by weakening the thesis it is indeed possible to prove

**Theorem 2.5.** The following conditions are equivalent for a topological preordered space $(E, \mathcal{T}, \leq)$

(a) $(E, \mathcal{T}, \leq)$ is a second countable completely regularly preordered space,

(b) $(E, \mathcal{T}, \leq)$ is separable and quasi-pseudo-metrizable.

Let us recall that in a pseudo-metric space, separability, second countability and the Lindelöf property are equivalent [15, Theor. 16.11]. Since in a quasi-pseudo-metrizable space the topology $\mathcal{T}$ is induced from the pseudo-metric $p + q$, separability of $(E, \mathcal{T})$ in (b) is equivalent to second countability.
We have also observed that every quasi-pseudo-metrizable space comes from a quasi-uniformity and hence is a completely regularly preordered space, thus the implication \((b) \Rightarrow (a)\) has been proved and it remains to prove \((a) \Rightarrow (b)\).

It should be noted that in \((a) \Rightarrow (b)\) we do not assume that \(E\) is regularly preordered. This does not mean that the assumption is stronger than expected because a completely regularly preordered space need not be regularly preordered \([30]\) Example 1]. This is a crucial difference with respect to the usual discrete-preorder version.

We do not use preorder regularity in theorem \(2.5\) because this condition is not necessary in order to obtain \((b)\), namely a separable quasi-pseudo-metrizable space need not be regularly preordered. An example has been given in \([30]\) Example 1]. This example shows also that there are separable quasi-pseudo-metrizable spaces which are not strictly quasi-pseudo-metrizable. Indeed, the latter spaces are perfectly normally preordered because of a result due to Patty \([11]\) Theor. 2.3] and hence regularly preordered.

A comparison with the discrete-preorder version is clarified by the following result

**Theorem 2.6.** Every second countable convex regularly preordered space is a completely regularly preordered space.

*Proof.* In \([31]\) Theor. 5.3] it has been proved that every second countable regularly preordered space is (perfectly) normally preordered. Since every convex normally preordered space is a completely regularly preordered space the thesis follows. \(\square\)

In order to prove theorem \(2.5\) we shall make use of the following result due to Nachbin \([5]\) Theor. 8], which generalizes the well known metrization theorem of Alexandroff and Urysohn.

**Theorem 2.7.** (Nachbin) A quasi-uniformizable preordered space (i.e. completely regularly preordered space) comes from a quasi-pseudo-metric if and only if the quasi-uniformity admits a countable base.

Given a preorder \(\leq\) we obtain an equivalence relation \(\sim\) through “\(x \sim y\) if \(x \leq y\) and \(y \leq x\)”. In the next proof \(E/\sim\) is the quotient space, \(\mathcal{T}/\sim\) is the quotient topology, and \(\subseteq\) is defined by, \([x] \subseteq [y]\) if \(x \leq y\) for some representatives. The quotient preorder is by construction an order. The triple \((E/\sim, \mathcal{T}/\sim, \subseteq)\) is a topological ordered space and \(\pi : E \to E/\sim\) is the continuous quotient projection.

*Proof of theorem 2.7.* As a first step let us show that there is a countable family \(\mathcal{C}\) of continuous isotone functions \(c_k : E \to [0, 1], k \geq 1\), such that \(x \leq y\) if and only if \(\forall k, c_k(x) \leq c_k(y)\). Indeed, defined for every continuous isotone function \(c\), \(U_c = \{(x, y) : c(x) \leq c(y)\}\), we have by complete preorder regularity \(G(\leq) = \bigcap_c U_c\). Note that since \(c\) is continuous \(U_c\) is closed in the product topology. But \(E\) is second countable thus \(E \times E\) is second countable and hence any arbitrary intersection of closed sets can be reduced to a countable intersection \([32]\) p.
There is therefore a countable family \( C \) of continuous isotone functions \( c_k \) such that \( G(\leq) = \bigcap_{k \in \mathbb{C}} U_c \) which is the thesis.

Since \( (E, \mathcal{T}, \leq) \) is completely regularly preordered it is convex, thus by [33, Prop. 2.3] every open set is saturated with respect to \( \pi \), namely if \( O \in \mathcal{T} \) then \( \pi^{-1}(\pi(O)) = O \), which implies that \( \pi \) is open (actually a quasi-homeomorphism). Since \( (E, \mathcal{T}) \) is second countable and \( \pi \) is open, we have that \( (E/\sim, \mathcal{T}/\sim) \) is second countable.

Since \( (E, \mathcal{T}, \leq) \) is a completely regular preordered space then \( (E/\sim, \mathcal{T}/\sim, \leq) \) is a completely regular ordered space (immediate from the definitions) hence closed ordered which implies that \( (E/\sim, \mathcal{T}/\sim) \) is Hausdorff. But again, since \( (E/\sim, \mathcal{T}/\sim, \leq) \) is a completely regular ordered space, \( (E/\sim, \mathcal{T}/\sim) \) is Tychonoff.

By Urysohn’s theorem \( (E/\sim, \mathcal{T}/\sim) \) is metrizable with a metric \( \hat{\rho} \).

Let us prove that the pseudo-metric \( \rho(x, y) := \hat{\rho}([x],[y]) \) generates the topology \( \mathcal{T} \). It is clear that the \( \rho \)-balls are \( \mathcal{T} \)-open since \( \rho = \hat{\rho} \circ (\pi \times \pi) \) which is continuous, thus the topology generated by \( \rho \) is coarser than \( \mathcal{T} \). For the other direction, let \( O \in \mathcal{T} \) and let \( x \in O \). We have to prove that there is some \( \rho \)-ball centered at \( x \) and contained in \( O \). Since \( E \) is a completely regular preordered space it is convex and we can assume that \( O \) is convex. Since \( \pi \) is open the set \( \pi(O) \) is open and convex thus there is some \( r > 0 \) such that \( \{y : \hat{\rho}([x],[y]) < r\} \subset \pi(O) \). But if \( \{w \in \{y : \hat{\rho}([x],[y]) < r\} \subseteq \pi(O) \) thus some representative \( w \) belongs to \( O \). As \( O \) is convex \( \pi^{-1}(\{w\}) \subset O \). We conclude that all the points in \( \pi^{-1}(\{y : \hat{\rho}([x],[y]) < r\}) = \{y : \rho(x,y) < r\} \) are contained in \( O \), which is the thesis. Note from the definition of \( \rho \) that \( \rho(x,y) = 0 \) implies \([x]= [y]\).

Now, the strategy is to construct the quasi-uniformity as the weak quasi-uniformity \( W \) of a countable family \( \mathcal{P} \) of continuous isotone functions with values in \([0,1]\). Let us recall that if \( f : E \to [0,1] \) is a function then the sets \( \{x \in E : f(x) - f(y) < 1/k\} \) for every natural \( k \geq 1 \) form a (countable) base for a quasi-uniformity on \( E \). If \( \mathcal{P} \) counts more than one function then \( W \) is given by the smallest filter containing all the single quasi-uniformities. The quasi-uniformity \( W \) admits a countable base if \( \mathcal{P} \) is countable, indeed a base is given by all the finite intersections of the base elements generating the single function quasi-uniformities.

As a first step we include the family \( C \) into \( \mathcal{P} \), in this way we obtain that \( \bigcap W = G(\leq) \) and that this equation cannot be spoiled by the inclusion in \( \mathcal{P} \) of arbitrary families of continuous isotone functions. We have therefore only to show that we can find a countable family \( Q \) of continuous isotone functions with values in \([0,1]\), such that the weak quasi-uniformity of that family induces a topology as fine as \( \mathcal{T} \) (with some abuse of notation we will keep the same symbol for the function on \( E \) or on \( E/\sim \)). Let \( \rho \) be the pseudo-metric on \( E \) and let \( \hat{\rho} \) be the metric on \( E/\sim \) mentioned above. For every \( n \geq 1 \) we consider a covering on \( E/\sim \) by open \( \hat{\rho} \)-balls of radius \( 1/n \), then for every point \([x] \in E/\sim \) we construct a pair of functions \( f^{(n)}_{[x]}, g^{(n)}_{[x]} : E/\sim \to [0,1] \), the former continuous and isotone and the latter continuous and anti-isotone such that \( f^{(n)}_{[x]}([x]) = g^{(n)}_{[x]}([x]) = 1 \) and \( \min(f^{(n)}_{[x]}, g^{(n)}_{[x]})([y]) = 0 \) whenever \( \hat{\rho}([x],[y]) \geq 1/n \).
(they exist by definition of completely regularly ordered space). The open sets \( V^{(n)}([x]) = E \setminus \{ [y] : \min(f^{(n)}_x, g^{(n)}_x)([y]) = 0 \} \) give an open covering of \( E \) and each of these sets is contained in an open ball of radius \( 1/n \). By the Lindelöf property implied by second countability \[15\] Theor. 16.9 there is a countable subcovering which corresponds to points \( [x_i^{(n)}] \) and functions \( f^{(n)}_{[x_i^{(n)}]}, g^{(n)}_{[x_i^{(n)}]} \). We add for each \( n \) and \( i \) the continuous isotone functions \( f^{(n)}_{[x_i^{(n)}]} \) and \( 1 - g^{(n)}_{[x_i^{(n)}]} \) to \( \mathcal{P} \) in such a way that the weak quasi-uniformity \( W \) satisfies \( \mathcal{I} = \mathcal{I}(W^*) \). Indeed, if \( O \supseteq x \), with \( O \in \mathcal{I} \) then \( \pi(O) \ni [x] \) and we have already proved that \( \pi(O) \in \mathcal{T}/\sim \) and \( \pi^{-1}(\pi(O)) = O \). There is some \( n \) such that the open \( \tilde{p} \)-ball of radius \( 2/n \) centered at \( [x] \) is contained in \( \pi(O) \). Since the sets \( \{ V^{(n)}([x_i^{(n)}]) \}_i \) give a covering there is some \( i \) such that \( [x] \in V^{(n)}([x_i^{(n)}]) \subset \pi(O) \), where the inclusion follows from the fact that the set \( V^{(n)}([x_i^{(n)}]) \) is contained in the \( \tilde{p} \)-ball of radius \( 1/n \), in particular \( f^{(n)}_{[x_i^{(n)}]}(x) > 0 \) and \( g^{(n)}_{[x_i^{(n)}]}(x) > 0 \). Let \( j \geq 1 \) be such that \( f^{(n)}_{[x_i^{(n)}]}(x) > 1/j \) and \( g^{(n)}_{[x_i^{(n)}]}(x) > 1/j \) and let \( U \cap V^{-1} \in \mathcal{W}^* \) be given by \( U = \{(x, y) : f^{(n)}_{[x_i^{(n)}]}(x) - f^{(n)}_{[x_i^{(n)}]}(y) < 1/j \} \). Let \( V = \{(x, y) : (1 - g^{(n)}_{[x_i^{(n)}]}(x)) - (1 - g^{(n)}_{[x_i^{(n)}]}(y)) < 1/j \} \) to which corresponds a neighborhood of \( x \) in the topology \( \mathcal{I}(W^*) \) given by \( (U \cap V^{-1})(x) = \{ y : f^{(n)}_{[x_i^{(n)}]}(x) - f^{(n)}_{[x_i^{(n)}]}(y) < 1/j \} \). \( g^{(n)}_{[x_i^{(n)}]}(x) - g^{(n)}_{[x_i^{(n)}]}(y) < 1/j \} \) \( y : f^{(n)}_{[x_i^{(n)}]}(y) > 0 \) and \( g^{(n)}_{[x_i^{(n)}]}(y) > 0 \) \( \pi^{-1}(V^{(n)}([x_i^{(n)}])) \) \( \in O \). This last inclusion proves that \( \mathcal{I} = \mathcal{I}(W^*) \).

We have shown that \((E, \mathcal{I}, \leq)\) is quasi-uniformizable where the quasi-uniformity admits a countable base thus \((E, \mathcal{I}, \leq)\) is quasi-pseudo-metrizable.

\[ \square \]

Lemma 2.8. Let \((E, \mathcal{I}, \leq)\) be a second countable completely regularly preordered space, then there is a countable family \( \mathcal{F} \) of continuous isotone functions, \( k \geq 1 \), \( f_k : E \to [0, 1] \) such that (i) \( \mathcal{I} \) is the initial topology generated by \( \mathcal{F} \), and (ii) \( x \leq y \) if and only if for every \( k \geq 1 \), \( f_k(x) \leq f_k(y) \).

Proof. An inspection of the proof of theorem 2.5 shows that we have already proved that there is a countable family \( \mathcal{P} \) of continuous isotone functions, \( k \geq 1 \), \( f_k : E \to [0, 1] \) such that (i) \( \mathcal{I} \) is the initial topology generated by \( \mathcal{P} \), and (ii) \( x \leq y \) if and only if for every \( k \geq 1 \), \( f_k(x) \leq f_k(y) \).

\[ \square \]

3 The ordered Hilbert cube

In this section we investigate the ordered Hilbert cube and its connection with (strict) quasi-pseudo-metrization.

Theorem 3.1. The property of being a quasi-pseudo-metrizable preordered space is hereditary.
Proof. Assume $E$ is quasi-pseudo-metrizable and let $p, q$ be a pair of conjugate quasi-pseudo-metrics. Let $S$ be a subspace then $x \leq_S y$ if and only if $p_S(x, y) = 0$ where $p_S = p|_{S \times S}$. Furthermore the induced topology $\mathcal{T}_S$ has a base of neighborhoods given by the $d$-balls intersected with $S$, $d = p + q$, thus by the $d_S$-balls, where $d_S = p_S + q_S = d|_{S \times S}$. □

In general it is not true that every open increasing (decreasing) set on the subspace $S$ is the intersection of an open increasing (resp. decreasing) set on $E$ with $S$. If this is the case $S$ is called a preorder subspace $[34, 35, 16]$. In a closed preordered space every compact subspace $S$ is a preorder subspace $[34]$, Prop. 2.6].

**Theorem 3.2.** The property of being a strictly quasi-pseudo-metrizable preordered space is hereditary with respect to preorder subspaces.

**Proof.** It is well known that convexity and the semiclosed preordered space property are hereditary. For the remainder of the proof it suffices to define $p_S = p|_{S \times S}$, $q_S = q|_{S \times S}$ where $S$ is a preorder subspace. Indeed, if $V \subset S$ is open increasing in $S$ there is $V'$ open increasing in $E$ such that $V = V' \cap S$. Let $x \in V$ then there is some $\epsilon > 0$ such that $P(x, \epsilon) \subset V'$ which implies $P_S(x, \epsilon) \subset V'$, where $P_S(x, \epsilon)$ is the $p_S$-ball of radius $\epsilon$ centered at $x$. The proof in the decreasing case is analogous. □

**Lemma 3.3.** If $(E, \mathcal{T}, \leq)$ is quasi-pseudo-metrizable preordered space, then it admits a quasi-pseudo-metric bounded by 1. If $(E, \mathcal{T}, \leq)$ is strictly quasi-pseudo-metrizable preordered space, then it admits a quasi-pseudo-metric bounded by 1 (in the sense of strict quasi-pseudo-metric spaces i.e. it generates $\mathcal{T}^+$ with the conjugate that generates $\mathcal{T}^\sharp$).

**Proof.** The function $h : \mathbb{R} \to [0, 1]$, $h(a) = \min(a, 1)$, is non-decreasing and sublinear, $h(a + b) \leq h(a) + h(b)$. If $p$ is a quasi-pseudo-metric then $p_1 = h(p)$ satisfies the triangle inequality by the sublinearity of $h$ and satisfies also $p_1(x, x) = h(p(x, x)) = h(0) = 0$ thus it is a quasi-pseudo-metric. Defined $q_1(x, y) = p_1(y, x) = h(q(x, y))$, we have that $d_1 = p_1 + q_1$ is a pseudo-metric which generates the same topology of $d = p + q$ (they have the same balls with radius smaller than 1) and furthermore, $p_1(x, y) = 0$ iff $p(x, y) = 0$.

The proof in the strict case is similar. The quasi-pseudo-metrics $p_1$ and $q_1$ are defined in the same way from $p$ and $q$, since $p_1$ shares with $p$ the same balls of radius less than 1, and since $q_1$ shares with $q$ the same balls of radius less than 1, the thesis follows. □

Let $(E_n, \mathcal{T}_n, \leq_n)$, $n \in \mathbb{N}$, be topological preordered spaces and let $(E, \mathcal{T}, \leq)$ be the topological preordered space in which $(E, \mathcal{T})$ is the product space $E = \prod_{n \in \mathbb{N}} E_n$ endowed with the product topology and $\leq$ is the product preorder: $x \leq y$ if for all $n \in \mathbb{N}$, $x_n \leq_n y_n$. We have the following

**Theorem 3.4.** The product topological preordered space $E = \prod_{n} E_n$ is quasi-pseudo-metrizable if and only if each $E_n$ is quasi-pseudo-metrizable.
Proof. If $E$ is quasi-pseudo-metrizable $E_n$ is quasi-pseudo-metrizable because it is preorder homeomorphic with a subset $S$ of $E$ obtained by fixing all the coordinates $x_k$ of $x$ to some value in $E_k$ but for $k = n$. One can then use theorem 5.1.

For the converse, let $p_n : E_n \times E_n \rightarrow [0, 1]$ be a quasi-pseudo-metric for $E_n$ bounded by 1 and endow $E$ with the quasi-pseudo-metric

$$p(x, y) = \sum_{n=1}^{\infty} p_n(x_n, y_n)/2^n.$$ 

The proof that $p$ is a quasi-pseudo-metric is straightforward. Let $q(x, y) = p(y, x)$ and analogously for $g_n$, $n \in \mathbb{N}$. The pseudo-metric $d = p + q$ reads $d(x, y) = \sum_{n=1}^{\infty} d_n(x_n, y_n)/2^n$ where $d_n = p_n + g_n$ is the pseudo-metric which generates the topology $\mathcal{T}_n$. According to [36] Theor. 14, Chap. 4] $d$ generates the product topology $\mathcal{T}$. Finally, $p(x, y) = 0$ if and only if for all $n \in \mathbb{N}$, $p_n(x_n, y_n) = 0$ which is equivalent to: for all $n \in \mathbb{N}$, $x_n \leq y_n$, that is, $x \leq y$.

One must be careful in trying to generalize the previous theorem to the strict case. It is known that the countable product of quasi-pseudo-metrizable spaces in the bitopological sense is quasi-pseudo-metrizable in the bitopological sense [10, 17]. This fact does not imply the existence of a simple corresponding theorem in the strict quasi-pseudo-metrization case for topological preordered spaces. The reason is that the product bitopology can be different from the product topology in the bitopological sense.

For $I$-spaces [34] (compare [35]), namely for topological preordered spaces for which the increasing and decreasing hulls of open sets are open, it is possible to prove a useful strict case generalization.

**Theorem 3.5.** If the product topological preordered space $E = \Pi_n E_n$ is strictly quasi-pseudo-metrizable, then each factor $E_n$ is strictly quasi-pseudo-metrizable, furthermore if $E$ is also an $I$-space then so are the factors $E_n$. If each factor $E_n$ is a strictly quasi-pseudo-metrizable $I$-space, then $E$ is a strictly quasi-pseudo-metrizable $I$-space. Finally, in this last case the upper topology on $E$ is the product of the upper topologies of the factors, and analogously for the lower topology.

Proof. Each $E_n$ is preorder homeomorphic with a subset $S$ of $E$ obtained by fixing all the coordinates $x_k$ of $x$ to some value in $E_k$ but for $k = n$. The subset $S$ just defined is actually a preorder subspace because if $V \subseteq S$ is open increasing then (omitting the preorder homeomorphism of $S$ with $E_n$) $\pi_n^{-1}(V)$ is open increasing and $\pi_n^{-1}(V) \cap S = V$, and analogously for the open decreasing sets. By theorem 5.2 $E$ is strictly quasi-pseudo-metrizable thus $S$ and hence $E_n$ is strictly quasi-pseudo-metrizable. Furthermore, if $O$ is an open set of $E_n$ then $\pi_n^{-1}(O)$ is an open set of $E$ and if $E$ is an $I$-space $i(\pi_n^{-1}(O)) = \pi_n^{-1}(i_{E_n}(O))$ is open, thus $\pi_n(\pi_n^{-1}(i_{E_n}(O))) = i_{E_n}(O)$ is open because the projection maps
are open \[15\] Theor. 8.6. The proof that \( d_{E_n}(O) \) is open is analogous. We conclude that each \( E_n \) is an \( I \)-space.

For the converse, let us prove that \( E \) is convex. Let \( O \) be an open set in the product topology and let \( x \in O \). There are open sets \( O_{i_1} \subset E_{i_1}, \ldots, O_{i_s} \subset E_{i_s}, x_{i_k} \in O_{i_k} \), such that \( \Pi_{n=1}^\infty W_n \subset O \), where \( W_n = O_{i_k} \) if \( n = i_k \) for some \( 1 \leq k \leq s \), or \( W_n = E_n \) otherwise. Recalling that each \( E_i \) is convex the sets \( O_{i_k} \) can be chosen to be intersections \( O_{i_k} = U_{i_k} \cap V_{i_k} \) where \( U_{i_k} \) is open decreasing and \( V_{i_k} \) is open increasing in \( E_{i_k} \). Evidently defined \( U' = \Pi_{n=1}^\infty W_n \) where \( Y_n = U_{i_k} \) if \( n = i_k \) for some \( 1 \leq k \leq s \), or \( Y_n = E_n \) otherwise, and \( V' = \Pi_{n=1}^\infty Z_n \) where \( Z_n = V_{i_k} \) if \( n = i_k \) for some \( 1 \leq k \leq s \), or \( Z_n = E_n \) otherwise, we have \( x \in U' \cap V' \subset \Pi_{n=1}^\infty W_n \subset O \) which proves that \( E \) is convex because \( U' \) is open decreasing in \( E \) and \( V' \) is open increasing in \( E \).

Let us prove that \( E \) is semiclosed preordered. Indeed, if \( x \in E \), using the definition of product order, \( i(x) = \bigcap_{n=1}^\infty E \cap \pi_n^{-1}(\pi_n(x)) \) from which we obtain that \( i(x) \) is closed because each \( i_{E_n}(x) \) is closed. Analogously, \( d(x) \) is closed.

Let \( p_n : E_n \times E_n \rightarrow [0, 1] \) be a quasi-pseudo-metric for \( E_n \) bounded by 1 and endow \( E \) with the quasi-pseudo-metric \( p(x, y) = \sum_{n=1}^\infty p_n(x_n, y_n)/2^n \). The proof that \( p \) is a quasi-pseudo-metric is straightforward. Let \( V \subset E \) be an open increasing set and let \( x \in V \) then by definition of product topology there are open sets \( O_{i_1} \subset E_{i_1}, \ldots, O_{i_s} \subset E_{i_s}, \) such that defined \( G = \Pi_{n=1}^\infty W_n \), where \( W_n = O_{i_k} \) if \( n = i_k \) for some \( 1 \leq k \leq s \), or \( W_n = E_n \) otherwise, we have \( G \subset V \). The sets \( i_{E_n}(O_{i_k}) \) are open and increasing by the \( I \)-space assumption.

We define the open set on \( E \), \( Q = \Pi_{n=1}^\infty R_n \) where \( R_n = i_{E_n}(O_{i_k}) \) if \( n = i_k \) for some \( 1 \leq k \leq s \), or \( R_n = E_n \) otherwise. Using the definition of product preorder, \( Q = (i(G)) \) (note that every base element on \( E \) has the form of \( G \), as we proved that \( Q \) is open, this formula shows, among the other things, that \( E \) is an \( I \)-space).

By strict quasi-pseudo-metrizability of \( E_{i_k} \) there are numbers \( r_{i_k} > 0 \) such that \( P_{i_k}(x_{i_k}, r_{i_k}) \subset i_{E_{i_k}}(O_{i_k}) \) where \( P_{i_k}(x_{i_k}, r_{i_k}) \) is a \( p_{i_k} \)-ball centered at \( x_{i_k} \). Let \( \epsilon \) be the minimum of \( r_{i_k}/2^k \) for \( k = 1, \ldots, s \).

Let us prove that \( P(x, \epsilon) \subset Q \subset V \). The last inclusion follows from the fact that \( V \) is increasing and \( G \subset V \). For the former inclusion, if \( y \in P(x, \epsilon) \) then \( p_{i_k}(x_{i_k}, y_{i_k})/2^k < \epsilon < r_{i_k}/2^k \) thus \( y_{i_k} \in P_{i_k}(x_{i_k}, r_{i_k}) \subset i_{E_{i_k}}(O_{i_k}) \). If we define \( w \in E \) to be that point such that \( w_n \in O_n, y_n \in i(w_n) \) for \( n = i_k, k = 1, \ldots, s \), and \( w_n = y_n \) otherwise, we have \( y = i(w) \) and \( w \in \Pi_{n=1}^\infty W_n = G \), thus \( y \in i(G) = Q \) is the thesis.

The inclusion \( P(x, \epsilon) \subset V \) proves that \( p \) generates \( \mathcal{T}^x \). The proof that \( q \) generates \( \mathcal{T}^q \) is analogous.

The inclusion \( Q \subset V \) proves that \( \mathcal{T}^q \) coincides with the product of the upper topologies on \( E_n \). Analogously, the product of the lower topologies on \( E_n \) gives \( \mathcal{T}^q \).

\[\square\]

The canonical quasi-pseudo-metric for the real line \( \mathbb{R} \) with the usual order is \( m(x, y) = \max(x - y, 0) \). With this choice \( \mathbb{R} \) becomes a strict quasi-pseudo-metric \( I \)-space. The interval \([0, 1]\) is a preorder subspace of the real line, thus
the quasi-pseudo-metric on \( \mathbb{R} \) induces on the interval \([0, 1]\) a quasi-pseudo-metric which is bounded by 1, and which makes \([0, 1]\) a strict quasi-pseudo-metrized space which is actually an \( I \)-space. From the previous theorem we get

**Proposition 3.6.** The Hilbert cube \( H = [0, 1]^\aleph_0 \) once endowed with the product topology and the product order is a strict quasi-pseudo-metric ordered \( I \)-space with quasi-pseudo-metric 
\[
 p(x, y) = \sum_{n=1}^{\infty} \max(x_n - y_n, 0)/2^n.
\]

**Theorem 3.7.** The following conditions are equivalent for a topological ordered space \((E, \mathcal{T}, \leq)\)

(a) \((E, \mathcal{T}, \leq)\) is a second countable completely regularly ordered space,

(b) \((E, \mathcal{T}, \leq)\) is order embeddable in the ordered Hilbert cube \(H\).

**Proof.** (b) \(\Rightarrow\) (a). Since \(H\) is the countable product of Hausdorff second countable spaces it is second countable \([13] \) Theor. 16.2]. As \(E\) is homeomorphic to a subset \(S\) of \(H\) it is second countable. Furthermore, the subspace \(S\) is quasi-pseudo-metrizable because this property is hereditary and hence a completely regularly ordered space. As \(E\) is order homeomorphic with \(S\) the thesis follows.

(a) \(\Rightarrow\) (b). Let \(\mathcal{F}\) be the family of continuous isotone functions \(f_k : E \to [0, 1]\) given by lemma \([2.8]\). They separate points because if it were \(f_k(x) = f_k(y)\) for all \(k\), then we would infer from \(f_k(x) \leq f_k(y)\) for all \(k\), \(x \leq y\), and from \(f_k(y) \leq f_k(x)\) for all \(k\), \(y \leq x\), from which it follows \(x = y\). By the embedding lemma \([15] \) Theor. 8.12) the function \(f : E \to H\) whose components are the functions \(f_k : E \to [0, 1]\), is an embedding. Actually, it is a preorder embedding because \(x \leq y\) if and only if for all \(k\), \(f_k(x) \leq f_k(y)\), which is equivalent to \(f(x) \leq f(y)\), as \(H\) is endowed with the product order.

At least in the compact case it is possible to infer that the topological preordered space is strictly quasi-pseudo-metrizable through the following

**Theorem 3.8.** Every compact quasi-pseudo-metrized preordered space is a strictly quasi-pseudo-metrized preordered space (with the same quasi-pseudo-metric).

**Proof.** We already know that the \(p\)-balls \(P(x, r) = \{y : p(x, y) < r\}\) are open and increasing because of the continuity of \(p\). We have to prove that every open increasing set is the union of \(p\)-balls. The proof for the decreasing case will be analogous. Let \(V\) be an open increasing set and let \(x \in V\), we have \(V \supseteq i(x) = \{y : p(x, y) = 0\} = \cap_{i=1}^{\infty} C_i\), where \(C_i\) are closed sets. Thus \(\emptyset = (M \setminus V) \cap \cap_{i=1}^{\infty} C_i = \cap_{i=1}^{\infty} (M \setminus V) \cap C_i\), but the sets \((M \setminus V) \cap C_i\) are closed, compact and satisfy the finite intersection property thus some of them must be empty, that is for some \(i\), \(C_i \subseteq V\), which reads \(P(x, 1/i) \subseteq V\).
Proof. Separability with respect to one topology implies separability with respect to any coarser topology thus $E$ is separable with respect to $\mathcal{T}^1$ and $\mathcal{T}^2$. The function $d = p + q$ is a pseudo-metric compatible with the topology $\mathcal{T}$. By Theor. 16.11, separability with respect to $\mathcal{T}$ implies second countability of $\mathcal{T}$. Let us prove the second countability of $\mathcal{T}^1$, the proof for $\mathcal{T}^2$ being similar. Let $\{c_1, c_2, \ldots\}$ be a countable family of functions which is dense according to $\mathcal{T}$ and define

$$U_{nm} = \{x : p(c_n, x) < 1/m\}, n = 1, 2, \ldots, m = 1, 2, \ldots$$

so that $\{U_{nm} : n = 1, 2, \ldots, m = 1, 2, \ldots\}$ is countable. We claim it is a base indeed let $y \in V \in \mathcal{T}^1$. By remark 1.1 there is some $m$ such that $P(y, 1/m) \subset V$. Consider the set $D(y, 1/(2m))$. This set is open in the topology $\mathcal{T}$ thus there is some $n$ such that $d(y, c_n) < 1/(2m)$ which implies $p(y, c_n) < 1/(2m)$ and $p(c_n, y) < 1/(2m)$. The set $U_{n2m}$ is therefore such that $y \in U_{n2m} \subset V$ (as $p(y, x) \leq p(y, c_n) + p(c_n, x) < 1/m$).

The next result clarifies that the difference between non-strict and strict quasi-pseudo-metrizable spaces is that both can be identified with subspaces of the ordered Hilbert cube but the latter types can also be identified with order subspaces of the ordered Hilbert cube.

**Theorem 3.10.** The following conditions are equivalent for a topological ordered space $(E, \mathcal{T}, \leq)$

(a) $(E, \mathcal{T}, \leq)$ is a separable strictly quasi-pseudo-metrizable space,

(b) $(E, \mathcal{T}, \leq)$ is order embeddable as an order subspace of the ordered Hilbert cube $H$.

*Proof.* (b) $\Rightarrow$ (a). If $E$ can be identified with an order subspace of the ordered Hilbert cube $H$ then $E$ is a strictly quasi-pseudo-metrizable since this property is hereditary with respect to order subspaces. Furthermore, $H$ has a second countable topology thus the topology of $E$ is second countable and hence separable.

(a) $\Rightarrow$ (b). Let $p$ be a quasi-pseudo-metric bounded by 1 for the strict quasi-pseudo-metrizable space $E$. Let $\{c_1, c_2, \ldots\}$ be a countable set which is dense according to $\mathcal{T}$ and define $f_n(x) = 1 - p(c_n, x)$, $g_n(x) = p(x, c_n)$, which are both continuous and isotone with value in $[0, 1]$ (Prop. 2.2). The countable family of functions $f_n$ is denoted $\mathcal{F}$ and the countable family of functions $g_n$ is denoted $\mathcal{G}$. We define $\mathcal{R} = \mathcal{F} \cup \mathcal{G}$. We are going to prove that (i) the coarsest topology on $E$ which makes all the elements of $\mathcal{F}$ upper semi-continuous is $\mathcal{T}^1$ and (ii) the coarsest topology on $E$ which makes all the elements of $\mathcal{G}$ lower semi-continuous $\mathcal{T}^2$. From that it follows, by convexity of $E$, that (i) the initial topology for $\mathcal{R}$ is $\mathcal{T}$. We are also going to prove that (ii) $x \leq y$ iff for every $r \in \mathcal{R}$, $r(x) \leq r(y)$.

Let $\mathcal{U}$ be the coarsest topology on $E$ which makes all the elements of $\mathcal{F}$ upper semi-continuous. $\mathcal{U}$ admits as subbase the sets of the form $f_n^{-1}((a, 1])$.
with $a \in [0, 1]$ which are open and increasing thus all the sets of $\mathcal{U}$ are open and increasing, that is, $\mathcal{U} \subset \mathcal{T}^i$.

For the converse, let $V$ be open increasing and let $x \in V$. There is some $\epsilon > 0$ such that $P(x, \epsilon) \subset V$, and there is some $c_i \in D(x, \epsilon/2)$. The $p$-ball $P(c_i, \epsilon/2)$ contains $x$ because $p(c_i, x) \leq d(c_i, x) = d(x, c_i) < \epsilon/2$, and $P(c_i, \epsilon/2) \subset P(x, \epsilon) \subset V$ because if $z \in P(c_i, \epsilon/2)$ we have $p(x, z) \leq p(x, c_i) + p(c_i, z) \leq d(x, c_i) + p(c_i, z) < \epsilon/2 + \epsilon/2 = \epsilon$ thus $z \in P(x, \epsilon)$. These observations imply that the function $f_i$ is such that $x \in f_i^{-1}((1 - \epsilon/2, 1]) \subset V$ which proves that $\mathcal{U}$ is as fine as $\mathcal{T}^i$ and hence equal to it. The proof of (i2) is analogous.

As for (ii), if $x \leq y$ we get $r(x) \leq r(y)$ because all the elements of $\mathcal{R}$ are isotone. If $x \not\leq y$ then $x \in E \setminus d(y)$ which is open increasing thus, by the just proved result, there is some $f_j \in \mathcal{F}$ and $r \geq 0$ such that $x \in f_j^{-1}((r, 1]) \subset E \setminus d(y)$ which implies $f_j(x) > r > f_j(y)$, thus setting $r = f_j$, $r(x) \not\leq r(y)$.

The collection $\mathcal{R}$ separates points because if $r(x) = r(y)$ for all $r \in \mathcal{R}$, then by the just proved result, $x \leq y$ and $y \leq x$ which implies by the order assumption, $x = y$. By the embedding theorem \cite[Theor. 8.12]{X}, the map $\rho : E \to H$ whose components are $r_{2i} = f_i$, $r_{2i+1} = g_i$, that is the functions of $\mathcal{R}$, is an embedding, and an order embedding because of (ii).

Let us prove that $\rho(E)$ is not only a subspace but in fact an order subspace of $H$. For simplicity we shall identify $E$ with $\rho(E)$ thus we shall omit the order homeomorphism between the two spaces. Let $V$ be an open increasing subset of $E$, we have to find an open increasing subset $V' \subset H$, such that $V' \cap E = V$.

For every $x \in V$ there is some $r_{2i} \in \mathcal{F} \subset \mathcal{R}$, $r_{2i} = f_i$, and $r \geq 0$ such that $x \in f_i^{-1}((r, 1]) \subset V$. The open set $V_x'$ on $H$ given by the product of all intervals $[0,1]$ but for the $(2i)$-th term which is $(r, 1]$, is open increasing and such that $V_x' \cap E = f_i^{-1}((r, 1]) \subset V$. Defined $V' = \bigcup_{x \in V} V_x'$ we have $V' \cap E = V$, which is the thesis. The proof in the decreasing case is analogous.

\[\square\]

Remark 3.11. In the ordered case theorem \ref{thm:3.8} follows also from theorem \ref{thm:3.10} because in the ordered case a separable quasi-pseudo-metrizable space can be regarded as a subset of the ordered Hilbert cube, thus if it is compact it is an order subspace \cite[Prop. 2.6]{Y} and hence a strictly quasi-pseudo-metrizable space.

4 Conclusions

In the framework of topological preordered spaces we have proved that the family of the second countable completely regularly preordered spaces coincides with the family of separable quasi-pseudo-metrizable spaces (Theor. \ref{thm:2.5}). The theorem is optimal as there are counterexamples if the latter family is narrowed to the strictly quasi-pseudo-metrizable spaces or the former family is enlarged to include the second countable regularly preordered spaces. We have also shown that in the ordered case the second countable completely regularly ordered spaces are essentially subspaces of the ordered Hilbert cube (Theor.
3.7). The difference with the strict case comes from the fact that with the strict condition the subspace can be chosen to be an order subspace (Theor. 3.10).

It remains open the problem of establishing conditions which, starting from second countability and the assumption that \( E \) is a completely regular pre-ordered space could allow one to prove that \( E \) is strictly quasi-pseudo-metrizable. We have shown that a compactness condition would be enough (Theor. 3.8) but this assumption is quite strong for applications.

Another direction for further investigation is that of the generalization of the Nagata-Smirnov-Bing metrization theorems to the topological preordered space case. Unfortunately, it seems that several arguments cannot be generalized and analogous quasi-pseudo-metrization results could not hold or could be much harder to prove.

Acknowledgments

I warmly thank P. Pageault for some useful suggestions. This work has been partially supported by GNFM of INDAM and by FQXi.

Appendix: Quasi-uniformities adapted to uniformities and preorders

A classical problem [5] asks to establish, given a uniformity \( O \) on a preordered space \( (E, \leq) \), if there is some quasi-uniformity \( U \) such that \( U^* = O \) and \( \bigcap U = G(\leq) \). In this appendix we provide a result which is connected to this problem as well as with the problem of quasi-pseudo-metrization of a topological preordered space.

The canonical quasi-uniformity \( R \) on \( \mathbb{R} \) is that generated by the quasi-pseudo-metric \( m(x, y) = \max(0, x - y) \). The dual quasi-uniformity \( R^{-1} \) is generated by the quasi-pseudo-metric \( n(x, y) = \max(0, y - x) \) and \( R^* \) is generated by the metric \( m + n = |x - y| \). Given a family of functions on a topological space \( E \) with values in \( \mathbb{R} \) one can induce both a weak uniformity or a weak quasi-uniformity on \( E \) depending as to whether one endow \( \mathbb{R} \) with \( R^* \) or \( R \).

**Theorem 4.1.** Let \( (E, \leq) \) be a preordered space, let \( O \) be a uniformity on \( E \), and let \( F \) be a family of uniformly continuous functions with value in \( \mathbb{R} \) with the properties

(i) \( O \) coincides with the weak uniformity generated by the set of functions \( F \),

(ii) \( x \leq y \) if and only if for every \( f \in F \), \( f(x) \leq f(y) \),

then the weak quasi-uniformity \( U \) generated by \( F \) is such that \( U^* = O \), \( \bigcap U = G(\leq) \), and the functions in \( F \) become quasi-uniformly continuous with respect to \( U \).

If \( F \) is countable then \( U \) admits a countable base, thus \( (E, U) \) is quasi-pseudo-metrizable (see theorem 2.7). If \( O \) admits a countable base and \( F(O) \) is second
countable (equivalently, $\mathcal{O}$ is induced by a pseudo-metric which makes $E$ a separable pseudo-metric space) then there is a subfamily $\mathcal{F}' \subset \mathcal{F}$ which is countable and satisfies (i) and (ii).

**Proof.** The weak uniformity $\mathcal{O}$ generated by $\mathcal{F}$ admits a subbase made of subsets of $E \times E$ of the form $(f \times f)^{-1}R$ where $f \in \mathcal{F}$ and $R \in \mathcal{R}^*$ (i.e. a base is made by the finite intersections of sets of that form). For each $R \in \mathcal{R}^*$ there are $U, V \in \mathcal{R}$ such that $U \cap V^{-1} \subset R$ (note that $U \cap V^{-1} \in \mathcal{R}^*$ by definition of the latter family) thus $\mathcal{O}$ admits a subbase made of subsets of $E \times E$ of the form $(f \times f)^{-1}(U \cap V^{-1}) = [(f \times f)^{-1}U] \cap [(f \times f)^{-1}V^{-1}] = [(f \times f)^{-1}U] \cap [(f \times f)^{-1}V^{-1}]^{-1}$.

The weak quasi-uniformity $\mathcal{U}$ generated by $\mathcal{F}$ admits a subbase made of subsets of $E \times E$ of the form $(f \times f)^{-1}U$ where $f \in \mathcal{F}$ and $U \in \mathcal{R}$ (i.e. a base is made by the finite intersections of sets of that form). A subbase for the quasi-uniformity $\mathcal{U}^*$ is then given by subsets of $E \times E$ of the form $[(f \times f)^{-1}U] \cap [(f \times f)^{-1}V^{-1}]$ for $U, V \in \mathcal{R}$. We conclude that $\mathcal{U}^* = \mathcal{O}$. Finally,

$$\bigcap_{f \in \mathcal{F}} \bigcap_{U \in \mathcal{R}} (f \times f)^{-1}U = \bigcap_{f \in \mathcal{F}} (f \times f)^{-1} \bigcap_{U \in \mathcal{R}} U = \bigcap_{f \in \mathcal{F}} (f \times f)^{-1}G(\leq_R) = \bigcup_{f \in \mathcal{F}} \{(x, y) : f(x) \leq f(y)\} = G(\leq).$$

The functions in $\mathcal{F}$ are quasi-uniformly continuous with respect to $\mathcal{U}$ by definition of weak quasi-uniformity.

If $\mathcal{F}$ is countable there is a subbase for $\mathcal{U}$ given by $(f_i \times f_i)^{-1}R_m$, where $f_i \in \mathcal{F}$ and $R_m = \{(x, y) \in \mathbb{R} \times \mathbb{R} : |x - y| < 1/m\}$. Since the subbase is countable the base obtained from all the possible finite intersections is also countable.

If $\mathcal{O}$ admits a countable base then it comes from a pseudo-metric $d$ (e.g. [35, Theor. 13, Chap. 6]). For a topological pseudo-metrizable space second countability is equivalent to separability [36, Theor. 11, Chap. 4] thus (i) $\mathcal{O}$ admits a countable base and $\mathcal{T}$ is second countable, is equivalent to (ii) $\mathcal{O}$ comes from a pseudo-metric $d$ such that $(E, d)$ is a separable pseudo-metric space.

Suppose $\mathcal{O}$ has a countable base $O_n$ and that $\mathcal{T}(\mathcal{O})$ is second countable, then for each $n$ we can find some integers $k_n, m \geq 1$, and some functions $f_1^{(n)}, f_2^{(n)}, \ldots, f_k^{(n)} \in \mathcal{F}$, such that $\bigcap_{i=1}^{k_n}(f_i^{(n)} \times f_i^{(n)})^{-1}R_m \subset O_n$, where $R_m = \{(x, y) \in \mathbb{R} \times \mathbb{R} : |x - y| < 1/m\}$. Consider the family $\mathcal{F}'$ which includes the functions $f_i^{(n)}$ so selected plus another countable family of uniformly continuous functions which we shall define in a moment. We have that the weak uniformity it generates is still $\mathcal{O}$. Since $\mathcal{T}(\mathcal{O})$ is second countable, the product topology $\mathcal{T} \times \mathcal{T}$ on $E \times E$ is second countable. Since the functions belonging to $\mathcal{F}$ are continuous and $G(\leq_R)$ is closed, each set $(f \times f)^{-1}G(\leq_R)$ for $f \in \mathcal{F}$, is closed in the product topology of $E \times E$. By second countability of $E \times E$, the intersection $G(\leq) = \bigcap_{f \in \mathcal{F}} (f \times f)^{-1}G(\leq_R)$ can be reduced to the intersection of a countable number of terms and we include the corresponding elements of $\mathcal{F}$ into $\mathcal{F}'$. The family $\mathcal{F}'$ is then countable and satisfies (i) and (ii).
