**Abstract**

**Background:** Infection, even outbreak, caused by *Cryptococcus gattii* (*C. gattii*) has been reported in Canada and the United States, but there were sparsely-reported cases of *C. gattii* in China. Our interest in occurrence, clinical manifestation, laboratory identification and molecular characterization of Chinese *C. gattii* strains leads us to this research.

**Results:** Out of 254 clinical isolates, initially identified as *Cryptococcus neoformans* (*C. neoformans*), eight strains were re-identified as *C. gattii*. Multi-locus sequence typing (MLST) showed genotype VGI accounted for the most (6 / 8), the other two strains were genotype VGII (VGIIa and VGIIb respectively) with 3 specific spectra of molecular weight about 4342, 8686, 9611 Da by MALDI-TOF MS. The minimal inhibitory concentrations (MICs) of Fluconazole with Yeast one was 2–4 times higher than that with ATB fungus 3 and MICs of antifungal agents against VGII strains were higher than against VGI strains. Comparative proteome analysis showed that 329 and 180 proteins were highly expressed by *C. gattii* VGI and VGII respectively. The enrichment of differentially expressed proteins was directed to Golgi complex.

**Conclusions:** Infection by *C. gattii* in China occurred sparsely. Genotype VGI was predominant but VGII was more resistant to antifungal agents. There was significant difference in protein expression profile between isolates of VGI and VGII *C. gattii*.

**Keywords:** Cryptococcus gattii, Genotype, Antifungal agents, Spectrum, Differential protein

**Background**

*Cryptococcus gattii* (*C. gattii*), one of the most common pathogenic cryptococcal species, primarily infects immunocompetent hosts, in contrast to *Cryptococcus neoformans* (*C. neoformans*), which mainly infects immunocompromised individuals [1, 2]. Previous studies revealed that *C. gattii* infection was restricted geographically to tropical and subtropical regions [1–3]. However, outbreaks have been recorded in temperate regions, such as British Columbian of Canada and Pacific Northwest of the United States [4, 5]. The majority of Chinese people reside in temperate and subtropical regions with climates suitable for fungal growth and the incidence of cryptococcal infection increased in recent years, unfortunately, little investigation has been carried out on this organism in China [6]. The objectives of the present study were to determine the frequency of *C. gattii* infection, to investigate clinical and microbiological characterization, and to analyze molecular features of the Chinese isolates.
Results
Identification and antifungal susceptibility profile of C. gattii isolates
Among 254 collected Cryptococcal strains, eight showed blue pigmentation on canavanine glycine bromothymol blue (CGB) agar and were characterized as C. gattii by matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS) with scores from 2.043 to 2.275, otherwise they were all identified as C. neoformans by VITEK 2 compact as seen in Table 1. The mass spectra obtained from eight C. gattii isolates were characterized by diverse spectra in the range between 2000 and 10,000 Da. Three specific spectra with molecular weight of about 4342, 8686, 9611 Da could be seen in two isolates of C. gattii VGII, they were absent in six isolates of C. gattii VGI, as shown in Fig.1. The dendrogram created by MALDI Biotype divided eight isolates into two groups of C. gattii VGI and VGII as shown in Fig.2. The MICs of six antifungal drugs to eight strains of C. gattii were listed in Table 1.

MLST analysis and genotyping
MLST confirmed six strains of C. gattii VGI and two strains of C. gattii VGII as indicated in supplementary Table 1. The 2 strains of isolate number 1 and 6 with C.gattii genotype VGII could be subtyped into VGIa and VGIIb respectively by further comparison with Vancouver Island reference stains of R265 and R272, as in supplementary Table 2. Some gene mutation existed in unlinked gene loci such as FTR1 and RAS1 as indicated in Fig.3.

Clinical information of patients infected with C. gattii
As shown in Table 1, the eight strains of C. gattii were isolated from eight patients. Two patients with isolate numbers of 2 and 6 were from Hainan and Yunnan Province, which were recognized as tropical areas. Three patients with isolate number 3 (from Chongqing city), 4 and 7 (from Fujian Province) were recognized as being from subtropical area. The other three patients with isolate numbers of 1, 5 and 8 were from Shandong Province, Inner Mongolia Autonomous Region and Henan Province, which were recognized as temperate regions. Information of patient infected with isolate number 3 was unavailable, the other 7 patients were immunocompetent young male adults, with age range of 21~60 years old. Their clinical and laboratory information were summarized in Table 2.

Differential protein analysis between C. gattii VGI and VGII
In this study, the proteome expression profiles of two strains of VGI and four strains of VGII C. gattii were created. A total of 3628 proteins were identified, of which, 2436 proteins were found in both VGI and VGII. C. gattii, however, C. gattii genotype VGI and VGII possessed 774 and 418 specific proteins respectively. Comparative proteome analysis showed that 329 and 180 proteins were highly expressed in C. gattii VGI and VGII.

| 5           | C. neoformans | blue                     | C. gattii (2.118)          | temperate regions                   | 57 VGII      | <0.5 | <1  | 0.25| 4   | <1  | 0.125|
| 6           | C. neoformans | blue                     | C. gattii (2.126)          | tropical areas                      | 7 VGII       | <2   | <1  | 0.25| 8   | 128 | 0.25|
| 7           | C. neoformans | blue                     | C. gattii (2.188)          | subtropical area                    | 57 VGII      | <0.5 | <1  | 0.25| 2   | <1  | 0.125|
| 8           | C. neoformans | blue                     | C. gattii (2.194)          | temperate regions                   | 161 VGII     | <1   | <1  | 0.25| 2   | <1  | 0.125|

Notes: a and b represented the method of ATB fungus 3 and Yeast one respectively; the abbreviations for antifungal drugs were: 5-FU 5-Flucytosine, AMB Amphotericin B, FCA Fluconazole, ITR Itraconazole, VRC Voriconazole, PSZ Posaconazole
as shown in Fig. 4. A cluster analysis of the differentially expressed proteins was shown in Fig. 5.

The information of GO term and KEGG metabolic pathway analysis indicated that the enrichment of differential expressed proteins between VGI and VGII was mainly directed to Golgi apparatus, Golgi membrane and Golgi vesicle as shown in Table 3. The most significant enriched metabolic pathways were oxidative phosphorylation, ribosome and metabolic pathway as shown in Fig. 6.

**Discussion**

**Selection of identification method and drug resistance of Chinese C. gattii strains**

*C. neoformans* and *C. gattii* are two important fungal pathogens for humans and animals. Both of them are round with capsule and positive urease test. These routine laboratory identification methods are unable to distinguish the two species [7]. Although there were several reports about infection of *C. gattii* from China [8–10], the number of *C. gattii* infections may have been underestimated because most laboratories utilize ink staining and biochemical methods, like VITEK 2 compact, for routine identification. CGB agar was recommended to identify *C. gattii* from *C. neoformans* due to its convenience and low cost [7], but it took longer time to get the result. Molecular methods would be faster and more accurate for differentiation of the two pathogenic Cryptococci species. However, they are not available in all clinical laboratories, where an accurate identification of species should be made in order to install the proper
treatment. In this study, eight strains of C. gattii were not only correctly identified but also grouped by MALDI-TOF MS with Bruker software 3.0. Of course, eight strains was not enough and more strains should be studied to obtain the spectrum difference between groups of C. gattii.

The results of antifungal susceptibility test by two kits were in good agreement, except that MICs of Fluconazole were 2~4 times higher by Yeast one than by ATB fungus 3. All the C.gattii isolates were susceptible to 5-Flucytosine, Amphotericin B, Itraconazole, Voriconazole and Posaconazole, only one strain was resistant to Fluconazole with MIC of 128 by Yeast one. However, interpretation of MICs of antifungal agents including Fluconazole for category of “susceptibility” or “resistance” was hampered by the lack of clinical breakpoints for C. gattii. Some previous studies have shown that C. gattii may be less susceptible to antifungal agents compared with C. neoformans. In a study from Taiwan, C. gattii was less susceptible to 5-Flucytosine and amphotericin B, and in Spain, MICs of Fluconazole, Voriconazole and Posaconazole to C. gattii were significantly higher [11–13]. The correlation between susceptibility profile and genotype of C. gattii has rarely been studied [14], our data indicated that antifungal agents exhibited higher MICs against isolates of genotype VGIII than genotype VGI, which agreed with the data of Hagen et al. and Lockhart et al. [14–17]. However, Clinical relevance between MIC breakpoint and epidemiological cut-off value (ECV) based on MIC distributions of wild-type strains has currently been studied on both C. neoformans and C. gattii isolates from Europe, USA, Australia, Brazil, Canada, India and South Africa. ECVs of Amphotericin B (0.5–1 μg/ml), 5-Flucytosine (4~16 μg/ml), Fluconazole (8~32 μg/ml) and other azoles varied similarly by molecular type for both C. neoformans and C. gattii [15, 16].

Molecular and epidemiical characteristics of Chinese C. gattii strains
Up to now, four genotypes of C. gattii have been detected, they were VGI, VGII, VGIII and VGIV. Lockhart and colleagues had reported that VGII and VGIII were the most-frequently identified isolates in America, VGIV was almost exclusively in Africa, and VG predominated in Europe, Australia and Asia [18]. C. gattii, as an important pathogen, caused outbreak in British Columbia, Canada and the Pacific Northwest, the United States. But 8 strains in our study were pathogens causing sporadic infections according to the strain origination and their isolation time.

Patient information and clinical characteristics
All the patients in our study had no recent travel history, the C. gattii infection occurred regionally and domestically. They were immunocompetent young male adults with age range of 21~60 years old, which was considered as the reason for increased exposure to environmental

![Figure 2: The dendrogram of 8 strains of C. gattii and 2 strains of C. neoformans](image-url)
sources and increased chance for infection [19]. Most patients had headache and fever, three patients showed neck stiffness, positive Kernig’s sign and meningeal lesions, meningeal enhancement or lacunar infarction by brain MRI. Most of them also demonstrated irregular nodule, consolidation and mass by lung CT, which was consistent with the research made by Ngamskulrungroj who indicated that C. gattii could cause fatal lung infection [20].

It was reported that host response varied based on the genotype of the organism and concomitant illnesses [21]. There was also study which revealed that C. gattii VGII strains were more virulent than VGI strains and VGIIa were even more virulent than VGIIb independent of their clinical or environmental origin [22]. In our study, all patients were treated by Fluconazole plus amphoterican B, most of them improved effectively without severe neurological sequelae. This might be explained by the fact that these patients infected by C. gattii VGI more than C. gattii VGII on the one hand, and on the other hand, two of them were infected with C. gattii VGII which showed sequence mutations in the gene location of RAS1 and FTR1 compared with reference strains R265 and R272 respectively. Whether the mutations were relevant to virulence decrease, further work needs to be done.

Analysis of differentially expressed protein in two genotypes of C. gattii

Our study showed significant difference in protein expression spectra between VGI and VGII. GO is a very
important tool of biological information. By establishing a set of controlled words with dynamic form, the attributes of genes and gene products in organisms can be described comprehensively. KEGG is the main public database with which the most important biochemical metabolic pathways and signal transduction pathways can be determined. Our results suggested that the differential protein of \textit{C. gattii} VGI and VG II was mainly located on the organelles associated with the Golgi body, which meant energy metabolism of \textit{C. gattii} might be involved in the difference of pathogenesis mechanism for different genotype of \textit{C. gattii}. Study on the secretory

protein and the secretory vesicles of the two genotypes of *C. gattii* would be beneficial to the understanding of the pathogenesis of *C. gattii*.

**Conclusions**

In spite that only 8 strains were available for analysis, our results demonstrated that *C. gattii* genotype VGI was predominant in China and *C. gattii* genotype VGII was more resistant to antifungal agents. *C. gattii* VGII isolates possessed obvious protein peaks with molecular weight of approximate 4342, 8686, 9611 Da. The full protein spectrum data of *C. gattii* were provided for the first time, a total of 3628 proteins were identified, 329 and 180 proteins were highly expressed by *C. gattii* VGI and VGII respectively. The enrichment of differentially expressed proteins between VGI and VGII was mainly directed to Golgi complex. It will lay a foundation for better understanding and further research on the pathogenic mechanism for different genotype of *C. gattii*.

**Methods**

**Collection and initial identification of clinical isolates**

A total of 254 clinical isolates initially identified as *C. neoformans* by biochemical methods were collected from seven hospitals in China, they were all stored at −80 °C. All the isolates were sub-cultured onto Sabouraud dextrose agar medium at 25 °C for 48~72 h and identified by VITEK 2 Compact (bioMérieux SA, France). Each isolate was also inoculated on canavanine-glycine-bromthymol blue (CGB) agar [23] at 25 °C for 24~120 h, The isolates which showed blue pigmentation on CGB agar were then subjected to further identification.

**Identification by MALDI-TOF MS**

Isolates were re-identified and analyzed by MALDI-TOF MS (Bruker, Daltonik, Bremen, Germany). Briefly, one single colony was smeared directly on the MALDI-TOF MS analysis plate and formic acid was added. After 3~5 min, matrix was added and the plate was put into the MALDI-TOF MS instrument with MALDI Biotyper software 3.0 (Bruker Daltonik GmbH) for species identification.
Table 3 Results of GO enrichment analysis for Cellular Component

| GO ID     | GO Term                  | Gene Ratio | Bg Ratio | P value     |
|-----------|--------------------------|------------|----------|-------------|
| GO:0005794| Golgi apparatus          | 40         | 51       | 3.26E-07    |
| GO:0000139| Golgi membrane           | 26         | 32       | 1.37E-05    |
| GO:0005798| Golgi-associated vesicle | 12         | 16       | 0.011314374 |
| GO:0031982| vesicle                  | 17         | 26       | 0.021147847 |
| GO:0030662| coated vesicle membrane  | 14         | 21       | 0.028770779 |
| GO:0044433| cytoplasmic vesicle part | 15         | 23       | 0.030922717 |

Fig. 6 Enrichment Analysis of differential proteins by KEGG metabolic pathway. Notes: The circle was used to represent the enrichment of each KEGG term, the diameter of the circle represented the number of differentially expressed genes commented to each KEGG term species, the color of the circle represented the significance of the corresponding KEGG term (p value corrected by FDR). Bottom transverse coordinate represented “Rich factor”, the larger the value, the higher the proportion of the number of differentially expressed genes to the total number of corresponding KEGG term gene.
identification and dendrogram analysis. Two strains of \textit{C. neoformans} were included as outgroup control.

**Analysis by multilocus sequence typing (MLST)**

Genomic DNA of each isolate identified as \textit{C. gattii} was then extracted using the TianGen TIANamp Yeast DNA Kit (Tiangen Biotech Beijing Co., LTD, China) complying with the manufacturer’s instruction, seven genes of unlinked loci were amplified, including six housekeeping genes (CAP59, GPD1, LAC1, PLB1, SOD1, URA5) and one non-coding region gene (IGS1) [24], bi-directional sequencing for each gene was then carried out, sequence comparison for each locus was done according to the method described by ISHAM Cryptococcal Working Group. Sequences were uploaded to the MLST Database for the \textit{C. neoformans/C. gattii} species complex (http://mlst.mycologylab.org) one by one. A sequence type (ST) number and seven allele type (AT) numbers were given to each isolate. New AT and ST number will be assigned for new sequence. To differentiate VGII subtypes, twelve unlinked genes (SX11a, TEF1, FTR1, CBP1, ICL1, HOG1, TOR1, STE7, TRR1, FHB1, RAS1, PKA1) were also amplified and sequenced according to the method of Fraser et al. [25], they were analyzed and compared with Vancouver Island strains of R265 and R272.

**Antifungal susceptibility test of \textit{C. gattii} isolates**

Antifungal susceptibility test was carried out by both ATB fungus 3 (bioMérieux SA, France) and Yeast one (Trek Diagnostic Systems Ltd., UK) following their instructions. \textit{Candida krusei} ATCC 6258 and \textit{Candida parapsilosis} ATCC 22019 were used for quality control.

**Clinical information of patients**

Under authorization of Medical Record Department, Clinical information of patients infected by \textit{C. gattii} was reviewed retrospectively, including age, sex, underlying diseases, symptoms, imaging findings, laboratory examinations and antifungal therapy.

**Analysis of differential proteins**

According to the regional distribution and the integrity of clinical data of the strains, six strains (4 of VGII and 2 of VGII) of \textit{C. gattii} were selected for proteome analysis. All the isolates were sub-cultured onto Sabouraud dextrose agar medium, incubated at 25°C for 48~72 h, the proteins were extracted from the strains. The protein concentration was 0.5 μg/μl, after being separated by SDS-PAGE electrophoresis (One-dimensional), the proteins were hydrolyzed and analyzed. Original mass spectrum files of 6 strains were imported into Maxquatt software (version 1.3.0.5) for analysis. The database source was for \textit{C. gattii} in Uniprot (http://www.proteome.com/). Plus or minus 15 ppm of polypeptide molecular weight, or missing 2 cutting sites were set as Maxquatt parameters, false discovery rate (FDR) for polypeptide identification was set as 0.01. A standard of \( p < 0.05 \) and 2-fold expression were considered as different proteins. The enrichment and pathway analysis was carried out by using the GO plot package of R language and KEGG online tool (http://david.ncifcrf.gov/, http://www.kegg.jp/kegg/pathway.html). The bubble diagram was drawn according to the R language ggplot2 package.

**Supplementary information**

Supplementary information accompanies this paper at https://doi.org/10.1186/s12866-020-01752-4.

**Additional file 1: Supplementary Table 1: MLST profiles and genotype of \textit{C. gattii} strains.**

**Supplementary Table 2: MLST profiles of 16 gene loci for \textit{C. gattii} strains with genotype VGII.**

**Abbreviations**

AMB: Amphotericin B; AT: Allele type; CGB: Canavanine glycine bromothymol blue; \textit{C. gattii}: Cryptococcus gattii; \textit{C. neoformans}: Cryptococcus neoformans; ECVs: Epidemiological MIC cut-off values; FCA: Fluconazole; FDR: False discovery rate; GO: Gene ontology; ITR: Itraconazole; KEGG: Kyoto encyclopedia of genes and genomes; MALDI-TOF MS: Matrix-assisted laser desorption/ionization time-of-flight mass spectrometry; MICs: Minimal inhibitory concentrations; MLST: Multi-locus sequence typing; PSZ: Posaconazole; ST: Sequence type; VRC: Voriconazole; 5-FU: 5-Flucytosine

**Authors’ contributions**

DXS designed and organized this study, revised the manuscript, LJ performed most of the experiments and wrote the manuscript, XYX performed most of the experiments and wrote the manuscript, XYX collected strains, JRC performed and analyzed MALDI-TOF MS. All authors read and approved the final manuscript.

**Funding**

This work was supported by Translational Medicine Project of Chinese General Hospital (grant no.2018TM-12). The funds are mainly used for the purchase of reagents, gene sequencing and proteomics analysis.

**Availability of data and materials**

The datasets used and/or analyzed during the current study are available from the corresponding author and first author on reasonable request.

**Ethics approval and consent to participate**

Not applicable.

**Consent for publication**

Not applicable.
Competition interests

The authors declare that there are no competing interests.

Ready to submit your research? Choose BMC and benefit from:
• fast, convenient online submission
• thorough peer review by experienced researchers in your field
• rapid publication on acceptance
• support for research data, including large and complex data types
• gold Open Access which fosters wider collaboration and increased citations
• maximum visibility for your research: over 100M website views per year

At BMC, research is always in progress.
