DIFFERENTIAL GALOIS THEORY AND ISOMONODROMIC DEFORMATIONS

DAVID BLÁZQUEZ-SANZ, GUY CASALE, AND JUAN SEBASTIÁN DÍAZ ARBOLEDA

ABSTRACT. Here we present a geometric setting for the differential Galois theory of $G$-invariant connections with parameters. As an application of some classical results on differential algebraic groups and Lie algebra bundles, we see that the Galois group with parameters of a connection with simple $G$ is determined by its isomonodromic deformations. This allows us to compute the Galois groups with parameters of the general Fuchsian special linear system and of Gauss hypergeometric equation.

1. INTRODUCTION

Differential Galois theory deals with some algebraic properties of differential equations. Its first version, dealing with systems of linear homogeneous ordinary differential equations was proposed by E. Picard and E. Vessiot at the end of the 19th century following the ideas of E. Galois on polynomial equations. The Galois group encodes the algebraic dependence relations between the coefficients of a fundamental matrix of solutions. There is a long history of generalizations, extensions, and different frameworks for such theory. In particular, in [CS06], P. Cassidy and M. F. Singer propose a parametrized Picard-Vessiot theory, dealing with equations of the form,

\[
\frac{\partial U}{\partial x} = A(x, s)U.
\]

The new aspect here, is that the Galois group does not only encode algebraic dependence relations between the coefficients of \( U \), but differential algebraic dependence relations as functions of the parameters \( s \). It is a theory about differential field extensions. A difficulty for its application is that the field of constants must satisfy some property (differentially closed) that is not usual for the fields of functions that appear in the realm of algebraic geometry.

Here, based on the ideas of B. Malgrange [Mal10b] and P. Cartier [Car08] we present another framework for the parameterized Picard-Vessiot theory that can be applied to the more usual situation of parametric families of \( G \)-invariant connections on algebraic varieties. It is a geometric theory, based in the prolongation of connections to the jet bundles and reduction of the structural group. The Galois groups are going to be differential algebraic groups. Following [Mal10a], we see these differential algebraic groups as systems of differential equations on the sections of an algebraic group bundle, compatible with the group operation.

In section 2 we give an exposition of the classical Galois theory for linear differential equations from a groupoid point of view. We pay attention to the case where the field of constant is bigger than \( \mathbb{C} \) in the last subsection.

We introduce the key objects of the theory in section 3: the Galois group and groupoid with parameters (Definition 3.15). The Galois group is introduced as an algebraic group subbundle of the group bundle of gauge automorphisms of the connection. In Theorem 3.20 we prove that it is, in fact, a differential algebraic group. Then we study the relation between the Galois group and isomonodromic deformations. Our key Lemma 3.22 which is a straightforward consequence of the topological definition of Galois groupoid, says that isomonodromic deformations form part of the equations of the Galois group. Our main, Theorem 3.23 shows that, for simple structural group, the Galois group with parameters is the group of gauge symmetries of the maximal isomonodromic deformation of the connection. It is a direct consequence of Kiso [Kis79] and Cassidy [Cas89] results. It gives us directly the Galois group with parameters of the general Fuchsian equation with trace free matrices, Example 3.24. It is the group of gauge symmetries of the Schlessinger system (seen as a partial \( \text{SL}_2 \)-connection). In section 4 we use previous results to determine the Galois group with parameters of Gauss hypergeometric equation.

Appendix A is an exposition of the theory of differential algebraic groups, following [Mal10a], from a geometric point of view. In Appendix B we explore the relation between the algebraic theory of [CS06] and ours.
2. **DIFFERENTIAL GALOIS GROUPOID OF A PRINCIPAL CONNECTION**

2.1. **On rational equivalence relations.** Let \( P \) be a complex irreducible algebraic affine smooth variety. We say that a Zariski-closed subset \( R \subset P \times P \) is a rational equivalence relation if:

1. there is an open subset \( P' \) such that \( R|_{P'} := R \cap (P' \times P') \) is an equivalence relation in \( P' \); and it satisfies any of the following equivalent conditions:
2. for any open subset \( U \) of \( P \), \( R \) is the Zariski closure of \( R|_{U} \);
3. irreducible components of \( R \) dominate \( P \) by projections.

**Remark 2.1.** Meromorphic equivalence relations, and generic quotients by them, have been already studied in [Gra86]. Galois correspondences shown here (Propositions 2.12, 2.18) can be seen as a direct consequence of results shown in SGA3 (Théorème 8.1).

**Remark 2.2.** Let us recall that the diagonal \( \Delta_P \subset P \times P \) is included in any rational equivalence relation, and it dominates \( P \) by projections. Therefore, if \( R \subset P \times P \) is an irreducible Zariski-closed subset then it is a rational equivalence relation if and only if it satisfies condition (1).

The following result is a particular case of [Mal01] Théorème 1.1.

**Theorem 2.3.** Let \( R \) be a rational equivalence relation in \( P \). There is an open subset \( P' \subset P \) such that \( R|_{P'} \) is a smooth equivalence relation in \( P' \).

**Example 2.4.** Let \( P = \mathbb{C}^2 \) with coordinates \( x, y \); we consider coordinates \( x_1, y_1, x_2, y_2 \) in \( P \times P \). Then, the closed subset \( R \) defined by the equation,

\[
x_1y_2 - x_2y_1 = 0,
\]

is rational equivalence relation in \( P \).

Rational equivalence relations are reflexive and symmetric. They are not in general transitive (as relations), but generically transitive, *i.e.* they become transitive after restriction to a dense open subset. For \( p \in P \) let us denote \([p]_R \) its class, the set of elements that are related by \( R \) to \( p \), *i.e.* \( \pi_1(\pi_2^{-1}([p])) \). It is a Zariski closed subset of \( P \). For generic \( p \in P \) we have \( \dim([p]_R) = \dim(R) - \dim(P) \). Thus, we say that a rational equivalence relation is *finite* if its dimension equals the dimension of \( P \); it implies that generic equivalence classes are finite.

2.1.1. **Irreducible rational equivalence relations.** Let us proceed to the description of all irreducible rational equivalence relations in \( P \). Let us consider \( \mathcal{F} \) a singular foliation in \( P \), and let \( P' \subset P \) be the complement of \( \text{sing}(\mathcal{F}) \). We say that \( \mathcal{F} \) is a foliation with algebraic leaves if for all \( p \in P' \) the leaf of \( \mathcal{F} \) that passes through \( p \) is open in its Zariski closure. A result of Gómez-Mont (Theorem 3 in [GM89]) ensures that there is an algebraic variety \( V \) and a rational dominant map \( f: P \dashrightarrow V \) such that the closure of a generic \( f \)-fibre is the closure of a leaf of \( \mathcal{F} \).

The foliation \( \mathcal{F} \) induces an rational equivalence relation in \( P \),

\[
R_\mathcal{F} = \{(p, q) \in \text{dom}(f)^2 \mid f(p) = f(q)\}.
\]

We say that the rational equivalence relation \( R_\mathcal{F} \) is the relation “to be on the same leaf of \( \mathcal{F} \”). For generic \( p \in P \) the class \([p]_{R_\mathcal{F}} \) is the Zariski closure of the leaf passing through \( p \).

**Lemma 2.5.** Let \( R \) be a rational irreducible equivalence relation in \( P \). Then, there is a singular foliation \( \mathcal{F} \) with algebraic leaves in \( P \) such that, \( R \) is the relation \( R_\mathcal{F} \) “to be on the same leaf of \( \mathcal{F} \)”.
Proof. Let us consider $R$ an irreducible rational equivalence relation in $P$. For each $p \in P$ we define $\mathcal{F}_p = T_p([p]_R)$. This $\mathcal{F}$ is a singular foliation of rank $\dim(R) - \dim(P)$. For generic $p \in P$ the leaf of $\mathcal{F}$ that passes through $p$ is the regular part of the irreducible component of $[p]_R$ that contains $p$. Then $\mathcal{F}$ is a foliation with algebraic leaves. We consider now an algebraic variety $V$ of dimension $\text{codim}(R)$ and a rational dominant map $f : P \to V$ such that for generic $p$ in $P$ the leaf that passes through $p$ is Zariski dense in $f^{-1}\{f(p)\}$. By definition $R_{\mathcal{F}}$ is a rational equivalence relation of the same dimension of $R$, and contained in $R$. From the irreducibility of $R$ we conclude $R = R_{\mathcal{F}}$.

Remark 2.6. In the open subset in which the foliation $\mathcal{F}$ is regular, leaves of $\mathcal{F}$ are irreducible. A generic equivalence class is the Zariski closure of a generic leaf of $\mathcal{F}$ thus it is irreducible.

In the previous discussion, the algebraic variety $V$ is defined up to birational equivalence. The field $f^* (\mathbb{C}(V)) = \mathbb{C}(P)^\mathcal{F}$ of rational first integrals of $\mathcal{F}$ allows us to recover the rational equivalence relation.

$$R_{\mathcal{F}} = \{(p, q) \in P \times P \mid \forall h \in \mathbb{C}(P)^\mathcal{F} \text{ if } p, q \text{ are in the domain of } h \text{ then } h(p) = h(q)\}$$

Let us recall that a subfield $\mathbb{K}$ of $\mathbb{C}(P)$ is relatively algebraically closed if all elements of $\mathbb{C}(P)$ that are algebraic over $\mathbb{K}$ are in $\mathbb{K}$. It is also well known that any function which is algebraic over $\mathbb{C}(P)^\mathcal{F}$ is also a first integral of $\mathcal{F}$. Thus, $\mathbb{C}(P)^R$ is relatively algebraically closed in $P$. Given a rational equivalence relation $R$, we can always consider its field of first integrals,

$$\mathbb{C}(P)^R = \{f \in \mathbb{C}(P) \mid \forall (p, q) \in R \text{ if } p, q \text{ are in the domain of } f \text{ then } f(p) = f(q)\}.$$ 

Reciprocally, from any relatively algebraically closed subfield $\mathbb{K} \subset \mathbb{C}(P)$ containing $\mathbb{C}$ we can recover a unique irreducible rational equivalence relation $R$ having $\mathbb{C}(P)^R = \mathbb{K}$. All this can be summarized in the following lemma.

Lemma 2.7. The following maps are bijective:

(a) The assignation $\mathcal{F} \rightsquigarrow R_{\mathcal{F}}$ that sends any singular foliation $\mathcal{F}$ with algebraic leaves to the irreducible rational equivalence relation “to be on the same leaf of $\mathcal{F}$.

(b) The assignation $R \rightsquigarrow \mathbb{C}(P)^R$ that sends any irreducible rational equivalence relation to its field of rational invariants.

(c) The assignation that sends any relatively algebraically closed subfield $\mathbb{K} \subset \mathbb{C}(P)$ to the foliation $\mathcal{F} = \ker(d\mathbb{K})$.

2.1.2. Finite rational equivalence relations. In this case $\dim R = \dim P$ and the projection $\pi_1 : R \to P$ is a dominant map. Thus, there is an open subset $P'$ such that $\pi_1 : R|_{P'} \to P'$ is a covering map. Note that, in order to construct this open set $P'$ we may remove not only the ramification but its orbit by the equivalence relation. Let us distinguish between two cases. First, let us assume $\pi_1|_{P'}$ is a trivial covering. We have the following result.

Lemma 2.8. Let us assume that there is an open subset $P' \subset P$ such that $\pi_1 : R|_{P'} \to P'$ is a trivial covering of order $d$. Then, there is free action of a finite group of order $d$, $G \subset \text{Aut}(P')$ such that:

$$R = \{(p, g(p)) \mid p \in P', g \in G\}.$$

Proof. Let $R|_{P'} = R_0' \cup R_1' \cup \ldots \cup R_{d-1}'$ be the decomposition of $R$ in irreducible components. For each $i = 0, \ldots, d - 1$ we define $g_i = \pi_2 \circ \pi_1|_{R_i'}^{-1}$. By the reflexive and transitive properties of $R$ we have that $\{g_0, \ldots, g_{d-1}\}$ is a group of regular automorphisms of $P'$. By definition of the $g_i$, a pair $(p, q)$ is in $R_i|_{P'}$ if and only if $q = g_i(p)$. Thus,

$$R|_{P'} = \{(p, g_i(p)) \mid p \in P', i = 0, 1, \ldots, d - 1\}.$$ 

□
The quotient by free actions of finite groups is well known (see, for instance [DG70]) and then there is a rational quotient map \( f : P \to P' / G \) of degree \( d \). Note that the finite group \( G \) acts on \( \mathbb{C}(P) \), and that this action fixes \( f^*(\mathbb{C}(P/G)) \) which is identified with \( \mathbb{C}(P)^G \). We have the following:

**Lemma 2.9.** The assignation \( R \rightsquigarrow \mathbb{C}(P)^R \) establishes a bijective correspondence between finite rational equivalence relations that are trivial coverings of open subsets of \( P \), and subfields \( \mathbb{K} \) of \( \mathbb{C}(P) \) such that \( \mathbb{K} \subset \mathbb{C}(P) \) is an algebraic Galois extension.

**Proof.** We need only to check that starting with a Galois subfield \( \mathbb{K} \subset \mathbb{C}(P) \) we recover a trivial covering. Let \( G \) be the group of automorphisms of \( \mathbb{C}(P) \) fixing \( \mathbb{K} \). They are birational automorphisms of \( P \). We may find an open subset \( P' \) invariant by those automorphisms. It is clear that this allows us to recover a trivial rational equivalence relation in \( P \). \( \square \)

Finally let us consider the second case in which \( \pi_1 : R|_{P'} \to P' \) is a covering, but not trivial. In such case there is finite covering \( \rho : P'' \to P' \) that trivializes \( \pi_1 \) (and \( \pi_2 \)). We define \( R'' \subset P'' \times P'' \) the pullback of the equivalence relation \( R|_{P'} \) to \( P'' \). Now, \( R'' \) is a trivial cover of \( P'' \) by \( \pi_1 \) or \( \pi_2 \), and thus there is a group of automorphisms of \( P'' \) inducing \( R'' \). We have proven the following.

**Lemma 2.10.** Let \( R \) be a finite rational equivalence relation in \( P \). There is an open subset \( P' \), a finite covering \( \rho : P'' \to P' \) and a finite group \( G \) of regular automorphisms of \( P'' \) such that:

\[
R = \{(\rho(p), \rho(g(p))) | p \in P'', g \in G\}.
\]

In this case, we have that the generic quotient \( P/R \) coincides with the quotient \( P''/G \) which is, up to birational equivalence, determined by its field of rational functions. We also have:

**Lemma 2.11.** The assignation \( R \rightsquigarrow \mathbb{C}(P)^R \) establishes a bijective correspondence between finite rational equivalence relations in \( P \), and subfields \( \mathbb{K} \) of \( \mathbb{C}(P) \) such that \( \mathbb{K} \subset \mathbb{C}(P) \) is an algebraic extension.

2.1.3. General rational equivalence relations. Finally, given a non-irreducible rational equivalence relation \( R \), we may proceed to construct the quotient in two steps. First, we consider \( R^0 \) the irreducible component containing the diagonal \( \Delta \). In this case, the quotient is given by Lemma 2.5. Then, we project the rational equivalence relation to the quotient, obtaining a finite rational equivalence relation. Then we apply Lemma 2.11. Finally we obtain that rational equivalence relations are determined by its fields of invariants, and vice-versa. Summarizing:

**Proposition 2.12** (Galois correspondence for rational equivalence relations). The map,

\[
\begin{align*}
\{ \text{rational equivalence relations in } P \} & \to \{ \text{subfields of } \mathbb{C}(P) \text{ containing } \mathbb{C} \} \\
R & \to \mathbb{C}(P)^R
\end{align*}
\]

is a bijective correspondence, and anti-isomorphism of lattices.

**Remark 2.13.** In the correspondence given by Proposition 2.12,

(1) irreducible rational equivalence relations are given by rational foliations with algebraic leaves and correspond to relatively algebraically closed subfields of \( \mathbb{C}(P) \);

(2) finite trivial rational equivalence relations correspond to actions of finite groups on open subsets of \( P \).

2.2. Rational groupoids. Let us fix \( B \) a complex irreducible smooth affine algebraic variety. By an algebraic groupoid acting on \( B \) we mean a smooth algebraic complex Lie groupoid \( (\alpha, \beta) : \mathcal{G} \to B \times B \).

**Definition 2.14.** A Zariski-closed subset \( \mathcal{H} \subset \mathcal{G} \) is called a rational subgroupoid if it satisfies:

(1) there is an open subset \( B' \) of \( B \) such that \( \mathcal{H}|_{B'} \) is a Lie subgroupoid of \( \mathcal{G}|_{B'} \); and it satisfies any of the following equivalent conditions:
(2) for any open subset $B'$ of $B$, $\mathcal{H} = \mathcal{H}|_{B'}$;

(3) irreducible components of $\mathcal{H}$ dominate $B$ by the source (or target) map.

**Remark 2.15.** If $\mathcal{H}$ is irreducible, it automatically satisfies (3); it contains the identity.

It is clear that the notion of rational subgroupoid generalizes that of rational equivalence relations, the latter being the rational subgroupoids of $B \times B$.

Let $\pi_G: \mathcal{G} \to B$ be an algebraic group bundle. The fibers of $\pi_G$ are complex algebraic groups where the group operation and inversion are defined as morphisms over $B$. There is a natural dictionary between group bundles over open subsets of $B$ and algebraic groups defined over $\mathbb{C}(B)$. Thus, sections of $\mathcal{G}$ define $\mathcal{G}$-subbundles of $\mathcal{G}$. That is, Zariski closed subsets $\mathcal{H} \subset \mathcal{G}$ that:

(1) there is an open subset $B'$ such that $\pi_G: \mathcal{H}|_{B'} \to B'$ is an algebraic group bundle;

(2) irreducible components of $\mathcal{H}$ dominate $B$ by projection.

**Example 2.16.** Let us consider $B = \mathbb{C}^2$, and $\mathcal{G} = \mathbb{C}^* \times B \times B$ where the composition law is given by $(\mu, x', y', x'', y'') \cdot (\lambda, x, y, x', y') = (\lambda \mu, x, y, x'', y'')$. The equation,

$$\lambda = \frac{x'y}{y'x}$$

defines an algebraic subgroupoid outside of the curve $xy = 0$, and thus,

$$\mathcal{H} = \{ (\lambda, x, y, x', y') : \lambda xy' - x'y = 0 \}$$

is a rational subgroupoid of $\mathcal{G}$, which is in fact, irreducible. However the intersection with the diagonal group bundle,

$$\mathcal{H} \cap \mathcal{G}_{\text{diag}} = \{ (\lambda, x, y) : (\lambda - 1)xy = 0 \}$$

has three irreducible components. Two of them, of equations $x = 0$ and $y = 0$ do not dominate $B$; the other one, of equation $\lambda = 1$ defines a rational group subbundle.

Hence, in order to define the diagonal part of a rational groupoid we have to restrict our attention to a suitable affine open subset. It is clear that the following definition does not depend on the choice of $B'$.

**Definition 2.17.** Let $\mathcal{H}$ be a rational subgroupoid of $\mathcal{G}$. Let us consider an affine subset $B' \subset B$ such that $\mathcal{H}|_{B'}$ is an algebraic groupoid acting on $B'$. We define the diagonal part of $\mathcal{H}$,

$$\mathcal{H}_{\text{diag}} = \mathcal{H}|_{B'} \cap \mathcal{G}_{\text{diag}}.$$
As before, if $L$ is irreducible then condition (1) implies condition (2).

By $\text{Iso}(P)$ we mean the groupoid of gauge isomorphisms of $P$; it is an algebraic groupoid acting on $B$. Elements of $\text{Iso}(P)$ are $G$-equivariant maps between fibers of $P$. This groupoid can be constructed as an associated bundle $\text{Iso}(P) = (P \times P)/G$. The class $[p, q]$ of a pair $(p, q)$ is identified with the unique $G$-equivariant map $\phi_{p,q} : P_{\pi(p)} \to P_{\pi(q)}$ satisfying $\phi_{p,q}(p) = q$.

By $\text{Gau}(P)$ we mean the group bundle of gauge automorphisms of $P$; the diagonal part of $\text{Iso}(P)$. It is an algebraic group bundle over $B$. Elements of $\text{Gau}(P)$ are $G$-equivariant maps from a fiber of $P$ to itself. This group bundle can also be constructed as the associated bundle, the balanced construction $P[\text{Adj}] = P \times \text{Adj}G$.

Given a rational subgroupoid $G \subset \text{Iso}(P)$, there is a corresponding field of rational invariants,

$$\mathbb{C}(P)^G = \{ f \mid f(p) = f(g(p)) \text{ for all } p \in P \text{ and } g \in G \text{ whenever } p \in \text{dom}(g) \text{ and } p, g(p) \text{ are in } \text{dom}(f) \}.$$ 

We would like to characterize rational subgroupoids of $\text{Iso}(P)$ in terms of their invariants. We say that a subfield $\mathbb{K} \subset \mathbb{C}(P)$ is $G$-invariant if right translations in $P$ map $\mathbb{K}$ into itself.

**Proposition 2.18** (Galois correspondence). The map,

$$\{\text{rational subgroupoids of } \text{Iso}(P)\} \to \{\text{G-invariant subfields of } \mathbb{C}(P) \text{ containing } \mathbb{C}\}$$

$$G \to \mathbb{C}(P)^G$$

is a bijective correspondence, and anti-isomorphism of lattices.

**Proof.** The quotient map $\pi_{P \times P} : P \times P \to \text{Iso}(P), (p, q) \mapsto \phi_{p,q}$ establishes a bijective correspondence between the set of subgroupoids of $\text{Iso}(P)$ and the set of $G$-invariant equivalence relations in $P$. This induces a bijective correspondence between the set of rational subgroupoids of $\text{Iso}(P)$ and $G$-invariant rational equivalence relations in $P$. Moreover, we have $\mathbb{C}(P)^G = \mathbb{C}(P)^{\pi_{P \times P}^\sim(G)}$.

The field of invariants of a $G$-invariant rational equivalence relation is $G$-invariant. Reciprocally, the rational equivalence relation corresponding to a $G$-invariant field, is $G$-invariant. Thus, by Proposition 2.12 we finish the proof.

**Remark 2.19.** Let us note that irreducible rational subgroupoids of $\text{Iso}(P)$ correspond to $G$-invariant relatively algebraically closed subfields of $\mathbb{C}(P)$ containing $\mathbb{C}$. Hence, they correspond to $G$-invariant singular foliations in $P$ with algebraic leaves.

### 2.4. Galois groupoid of a partial connection.

Here we give a geometric presentation based on rational subgroupoids of the classical Galois theory for $G$-invariant connections. The ideas of this section can be found in [Car08], see also [Mal10b] for a non linear version. Let us consider $G$ and $\pi : P \to B$ as in section 2.3. Additionally, we also consider a singular foliation $\mathcal{F}$ in $B$.

**Definition 2.20.** A rational partial flat Ereshmann connection in the direction of $\mathcal{F}$ in $P$ is a $\pi$-projectable, singular foliation $\mathcal{D}$ in $P$ of the same rank that $\mathcal{F}$ such that $\pi_*(\mathcal{D}) = \mathcal{F}$.

*From now on we will write $\mathcal{F}$-connection, or just connection, to refer to partial flat Ereshmann connections.*

A local analytic section $u$ of $P$ is $\mathcal{D}$-horizontal if $\mathcal{D}_{u(x)} \subset du(T_x B)$ for each $x$ in the domain of $u$. This means that each restriction of $u$ to a leaf $\mathcal{L}$ of $\mathcal{F}$ is $\mathcal{D}|_{\pi^{-1}(\mathcal{L})^\sim}$ horizontal, and vice versa. A vector field in $P$ tangent to $\mathcal{D}$ is also called $\mathcal{D}$-horizontal. Given a local analytic vector field $X$ tangent to $\mathcal{F}$ in $B$, there is a unique $\mathcal{D}$-horizontal vector field $\tilde{X}$ in $P$ such that $\pi_*(\tilde{X}) = X$. This $\tilde{X}$ is called the $\mathcal{D}$-horizontal lift of $X$. It is clear that if $X$ is a rational vector field then $\tilde{X}$ is also a rational vector field, moreover, if $X$ is regular in $B' \subset B$ and $\mathcal{D}$ is regular in $\pi^{-1}(B')$ then $\tilde{X}$ is regular in $\pi^{-1}(B')$. The $\mathcal{D}$-horizontal lifting is compatible with the Lie bracket $[X, Y] = [\tilde{X}, \tilde{Y}]$. 
We say that $\mathcal{D}$ is $G$-invariant if for each $g \in G$ we have $R_g(\mathcal{D}) = \mathcal{D}$. We say that $\mathcal{D}$ is regular if it is a regular foliation. After replacing $B$ by a suitable affine subset, we may assume that any $G$-invariant rational $\mathcal{F}$-connection $\mathcal{D}$ is regular.

Let $\mathcal{D}$ be a $G$-invariant rational foliation on $P$. We consider the field $\mathbb{C}(P)^{\mathcal{D}}$ of rational first integrals of the foliation. This field is, by definition, $G$-invariant. Thus, by Proposition 2.18 it corresponds to an irreducible rational subgroupoid of $\text{Iso}(P)$. The following definition is equivalent to that given in [Dav16].

**Definition 2.21.** The Galois groupoid of $\mathcal{D}$ is the rational subgroupoid $G\text{Gal}(\mathcal{D})$ of $\text{Iso}(P)$ such that $\mathbb{C}(P)^{G\text{Gal}(\mathcal{D})} = \mathbb{C}(P)^{\mathcal{D}}$. The Galois group bundle is the diagonal part of the Galois groupoid, $\text{Gal}(\mathcal{D}) = G\text{Gal}(\mathcal{D})^{\text{diag}}$. It is a rational group subbundle of $\text{Gau}(P)$.

By definition, it is clear that $G\text{Gal}(\mathcal{D})$ is irreducible in the Zariski topology. The Galois group bundle may not be irreducible.

**Remark 2.22.** The classical case of Picard-Vessiot theory corresponds to the case in which the foliation $\mathcal{F}$ has no rational first integrals, i.e., $\mathbb{C}(B)^{\mathcal{F}} = \mathbb{C}$. This setting has been exposed in [BSC17]. The fiber of the Galois group bundle is isomorphic to the classical Galois group. The intrinsic Galois group is the algebraic $\mathbb{C}(B)$-group whose elements are the sections of the Galois group bundle.

**Remark 2.23.** The Galois group bundle admits also a structure of differential algebraic group. The induced associated connection $\text{Adj}(\mathcal{D})$ is a partial group connection (see Appendix A) in $\text{Gau}(P)$. It restricts to the group subbundle $\text{Gal}(\mathcal{D})$. Thus, the pair $(\text{Gal}(\mathcal{D}), \text{Adj}(\mathcal{D}))$ can be seen as a differential algebraic group of order 1. This differential algebraic group structure was already pointed out by Pillay in [Pil04].

**Remark 2.24.** As the group bundle $\text{Gau}(P) \to B$ admits two equivalent descriptions, so the associated connection does. We may consider the distribution $\mathcal{D} \times \mathcal{D}$ in $P \times P$. This distribution is $G$-invariant under the diagonal action, thus it projects onto a distribution $\mathcal{D} \boxtimes \mathcal{D}$ in $\text{Iso}(P)$. The intersection of this distribution with the tangent bundle $T(\text{Gau}(P))$ gives us the associated connection $\text{Adj}(\mathcal{D})$.

**Remark 2.25.** The Galois groupoid can be also constructed geometrically as the smallest rational subgroupoid of $\text{Iso}(P)$ which is tangent to the distribution $\mathcal{D} \boxtimes \mathcal{D}$, see [Dav16] or [Car08].

**Remark 2.26.** By construction, the action $\text{Gau}(P) \times_B P \to P$ maps the distribution $\text{Adj}(\mathcal{D}) \times_B \mathcal{D}$ onto $\mathcal{D}$. Therefore, $\text{Adj}(\mathcal{D})$ is the equation of gauge symmetries of $\mathcal{D}$. A gauge transformation is $\text{Adj}(\mathcal{D})$-horizontal if and only if it has the property of transforming $\mathcal{D}$-horizontal sections into $\mathcal{D}$-horizontal sections.

2.5. **Connections with parameters.** Let us also consider a submersion $\rho: B \to S$, so that we have commutative diagrams as follows,

\[\begin{array}{ccc}
P & \xrightarrow{\pi} & B \\
\downarrow{\pi} & & \downarrow{\rho} \\
S & \xrightarrow{\rho^*} & C(S)
\end{array}\]

\[\begin{array}{ccc}
P & \xrightarrow{\pi} & \mathbb{C}(P) & \xrightarrow{\pi^*} & \mathbb{C}(B) \\
\downarrow{\rho^*} & & \downarrow{\rho^*} \\
C(S) & \leftarrow & \mathbb{C}(S)
\end{array}\]

we assume that the fibers of $\bar{\pi}$ are irreducible. Let $\mathcal{F}$ be the foliation with algebraic leaves defined by $\ker(dp)$. By a $G$-invariant connection in $P$ with parameters in $S$ we mean a $G$-invariant $\mathcal{F}$-connection $\mathcal{D}$ in $P$ [Mal10a] [Mal10b].

For each $s \in S$ we denote $B_s = \rho^{-1}(s)$, $P_s = \pi^{-1}(s)$, and $\pi_s = \pi|_{P_s}$. Thus, $\pi_s: P_s \to B_s$ is a principal fiber bundle with structure group $G$. The foliation $\mathcal{D}$ is tangent to $P_s$ its restriction $\mathcal{D}_s$ is a $G$-invariant connection in $P_s$.

We identify $C(S)$ with its image in $C(B)$ by $\rho^*$ and $C(B)$ with its image in $C(P)$ by $\pi^*$ so that we have a sequence of extensions, $C(S) \subset C(B) \subset C(P)$. Note that $C(B)$ is the fixed field $C(P)^G$ of rational invariants by the action of $G$ and $C(S)$ is the field $C(B)^{\mathcal{F}}$ of rational first integrals of $\mathcal{F}$. 

By $\text{Iso}_S(P)$ we mean the subgroupoid of $\text{Iso}(P)$ consisting on fiber isomorphisms that respect the projection $\rho$.

**Remark 2.27.** In terms of Proposition 2.18 $\text{Iso}_S(P)$ corresponds to the subfield $\mathbb{C}(S) \subset \mathbb{C}(P)$ and to the equivalence relation $P \times_S P$. Thus, we have a bijective correspondence between irreducible rational subgroups of $\text{Iso}_S(P)$ and $G$-invariant subfields of $\mathbb{C}(P)$ containing $\mathbb{C}(S)$.

**Proposition 2.28.** Let $\mathcal{D}$ be a $G$-invariant connection with parameters in $S$. We have $\text{GGal}(\mathcal{D}) \subset \text{Iso}_S(P)$.

**Proof.** Taking into account $\mathbb{C}(S) \subset \mathbb{C}(P)^\mathcal{D}$ we conclude using Remark 2.27. \hfill $\square$

### 3. The parameterized Galois groupoid of a connection

#### 3.1. Prolongation of a principal bundle.

Two germs of analytic sections of $P$ at $x \in B$ have the same jet of order $k$ if they are tangent up to the order $k$. This means, that in any analytic system of coordinates, they have the same power series development up to degree $k$. The space $J_k(P/B)$ of sections is a smooth affine algebraic variety and then $J(P/B) = \lim J_k(P/B)$ is a smooth pro-algebraic affine variety. The jet of order $k$ at $x \in B$ of the section $u$ is denoted by $j_k^x u$, and the section of $J_k(P/B)$ that assigns to each $x$ in the domain of $u$ the jet $j_k^x u$ is denoted by $j_k u$ (we omit the index $k = \infty$ for jets of infinite order).

By $\mathcal{O}_{J_k(P/B)}$ we understand the ring of regular functions in $J_k(P/B)$ with rational coefficients in $B$, that is, $\mathcal{O}_{J_k(P/B)} = \mathbb{C}(B) \otimes_{\mathbb{C}[B]} \mathbb{C}[J_k(P/B)]$. Elements of $\mathcal{O}_{J_k(P/B)}$ are regular differential functions of order $k$ with rational coefficients in $B$, or equivalently, regular differential functions in $J_k(P/B')$ for some open subset $B' \subset B$. We have a chain of ring extensions:

$$\mathbb{C}(B) \subset \mathcal{O}_{P/B} \subset \mathcal{O}_{J_1(P/B)} \subset \cdots \subset \mathcal{O}_{J_k(P/B)} \subset \cdots \subset \mathcal{O}_{J(P/B)}.$$

#### 3.1.1. Differential structure of $\mathcal{O}_{J(P/B)}$.

There exists a total derivative prolongation: if $X$ is a rational vector field in $B$ with domain of regularity $B' \subset B$ then its total derivative operator $X^\text{tot}$ is a derivation of the ring of differential functions, defined by the rule,

$$(X^\text{tot} F)(j_x^{k+1} u) = (X(F \circ j_x^k u))(x),$$

for any differential function $F$ of order $k$; $X^\text{tot}$ is a derivation of $\mathcal{O}_{J(P/B)}$. Note that the total derivative increases the order of differential functions, thus $X^\text{tot}$ is not a rational vector field in $J_k(P/B)$ for $k$ finite.

We consider the differential ring $(\mathcal{O}_{J(P/B)}, \mathcal{X}_{\text{rat}}(B))$. This is a $\mathcal{X}_{\text{rat}}(B)$-finately generated differential ring over $\mathbb{C}(B)$.

**Remark 3.1.** Here we work with a broader definition of differential field than usual (cf. [Kol73]). We consider a differential field to be a field endowed with an arbitrary Lie algebra of derivations. However, it is always possible to choose a finite commuting basis of $\mathcal{X}_{\text{rat}}(B)$ in order to recover the usual definition. For instance, let us take a transcendence basis of $\mathcal{C}(B)$ over $\mathbb{C}$. Then, the partial derivatives w.r.t. the basis elements are commuting rational vector fields spanning $\mathcal{X}_{\text{rat}}(B)$. Their corresponding total derivative operators are a basis of derivations form $\mathcal{O}_{J(P/B)}$. 
3.1.2. Prolongation of rational vector fields in $P$. Given a local analytic vector field $Y$ in $P$, its $k$-th prolongation $Y^{(k)}$ to $J_k(P/B)$ is obtained geometrically in the following way. Let us assume that $Y$ has a real flow $\{\sigma_t\}_{t \in \mathbb{R}}$ in a neighborhood of $p \in P$, let $x = \pi(p)$ and $u$ be a local section such that $u(x) = p$. Let $\gamma_u$ be the graph of $u$. For small $t$ we have that $\sigma_t(\Gamma_u)$ is, around $x$, also the graph of a local section that we name $u_t$. Then,

$$Y^{(k)}(j^k_x u) = \left. \frac{d}{dt} \right|_{t=0} j^k_{\sigma_t(p)} u_t.$$  

Thus, the flow of $Y^{(k)}$ is the projection in the jet space of the flow naturally induced by $Y$ in the space of pointed germs of submanifolds of $P$. It is easy to check that prolongation of vector fields is compatible with the Lie bracket $[X,Y]^{(k)} = [X^{(k)},Y^{(k)}]$. The prolongation $Y^{(k)}$ of a regular vector field $Y$ is also regular. Thus, if $Y$ of a rational vector field in $P$ whose domain of definition contains an open subset of the form $\pi^{-1}(B')$ with $B'$ open in $B$ then $Y^{(k)}$ is a derivation of $\mathcal{O}_{J_k(P/B)}$. This prolongation is possible up to arbitrary order, so that we obtain a derivation $Y^{(\infty)}$ of $\mathcal{O}_{J(P/B)}$ that respects the order of differential functions.

3.1.3. Homogeneous structure of the fibers. In general, if $G \to B$ is a group bundle, the group composition lifts to the jets of sections of $G$,

$$J_k(G/B) \times_B J_k(G/B) \to J_k(G/B), \quad (j^k_x g, j^k_x h) = j^k_x (gh).$$

Thus, for all $k$, $J_k(G/B) \to B$ is an algebraic group bundle and $J(G/B) \to B$ is a pro-algebraic group bundle.

Let us consider the trivial group bundle $G \times B \to B$; $J_k(G/B)$ will stand for $J_k(G \times B)$. There is a natural fibered action of this group bundle on $J_k(P/B)$,

$$J_k(P/B) \times_B J_k(G/B), \quad (j^k_x u, j^k_x g) \mapsto j^k_x (u \cdot g)$$

so that, for all $x \in B$, $J_k(P/B)_x$ becomes a principal homogeneous space for the action of the algebraic group $J_k(G/B)_x$. Those actions are compatible with the truncations of order; hence, taking the limit to infinite order we have that $J(P/B)_x$ is a principal homogeneous space for the action of the pro-algebraic group $J(G/B)_x$.

3.2. Prolongation of a principal connection. The $G$-invariant integrable distribution $\mathcal{D}$ defines closed subsets $\Gamma_k(\mathcal{D}) \subset J_k(P/B)$. They consist of $k$-jets of $\mathcal{D}$-horizontal sections. This closed subset $\Gamma_k(\mathcal{D})$ is the algebraic differential equation of order $k$ associated to $\mathcal{D}$. The chain of maps,

$$\Gamma(\mathcal{D}) = \lim_{\to} \Gamma_k(\mathcal{D}) \to \ldots \to \Gamma_{k-1}(\mathcal{D}) \to \ldots \Gamma_1(\mathcal{D}) \to \Gamma_0(\mathcal{D}) \to P,$$

are surjective.

$\Gamma_k(\mathcal{D})$ is defined by a radical ideal $\mathcal{E}_k(\mathcal{D})$ of $\mathcal{O}_{J_k(P/B)}$. Indeed, from the Frobenius integrability condition (flatness of $\mathcal{D}$) we obtain that $\mathcal{E}(\mathcal{D})$ is the radical $\mathcal{X}_{\text{rat}}(B)$-differential ideal of $\mathcal{O}_{J(P/B)}$ spanned by $\mathcal{E}_1(\mathcal{D})$. For each $k$, $\mathcal{E}_k(\mathcal{D})$ is the intersection of $\mathcal{E}(\mathcal{D})$ with the ring $\mathcal{O}_{J_k(P/B)}$. The ring of differential functions on horizontal sections is the $\mathcal{X}_{\text{rat}}(B)$-differential ring quotient $\mathcal{O}_{\Gamma(\mathcal{D})} = \mathcal{O}_{J(P/B)}/\mathcal{E}(\mathcal{D})$.

The composition with $\rho$ induces a map $\rho^* : J_k(G/S) \to J_k(G/B)$. Therefore we also have an action defined over $S$,

$$J_k(P/B) \times_S J_k(G/S), \quad (j^k_x f, j^k_x g) \mapsto j^k_x (f \cdot (\rho \circ g)).$$

**Proposition 3.2.** The action of $J_k(G/S)_{\rho^*(x)}$ on $\Gamma_k(\mathcal{D})_x$ is free and transitive for any $x \in B$.

**Proof.** Let $j^k_x u$ and $j^k_x v$ be in $\Gamma_k(\mathcal{D})_x$. Representatives $u$ ans $v$ can be taken as $\mathcal{D}$-horizontal sections defined in a neighborhood of $x$. There is a unique section $g$ defined in this neighborhood $G$ such that $u = v \cdot g$. 

Taking into account the \( u \) and \( v \) are \( \mathcal{D} \)-horizontal, we have that \( g \) is constant along the fibers of \( \rho \), so it can be thought as a function from a neighborhood of \( \rho(x) \) in \( S \) to \( G \). Finally we have, \( j^k_x u = (j^k_x u) \cdot (j^k_{\rho(x)} g) \).

**Remark 3.3.** It is important to note that the action is compatible with the truncation maps \( J_{k+1}(G, S) \to J_k(G/S) \) and \( \Gamma_k(\mathcal{D})) \to \Gamma_k(\mathcal{D}) \). Hence, we have that \( J(G/S)_{\rho(x)} \) acts free and transitively in \( \Gamma(\mathcal{D}) \).

### 3.2.1. Trivialization of \( J(G/S) \)

By Proposition 3.2 we have that \( \Gamma(\mathcal{D}) \to B \) is a bundle by principal homogeneous spaces. However, the structure group varies with the parameter in \( S \). In order to have a principal bundle structure we should trivialize the group bundle \( J(G/S) \).

Let \( m \) be dimension of \( S \) and \( \tau_{m,k} G \) be the generalized tangent bundle of \( G \) of rank \( m \) and order \( k \), i.e., the space of jets of order \( k \) of local analytic maps from \( (\mathbb{C}^m, 0) \) to \( G \). It is an algebraic group, with the composition law, \( (j^k_0 g)(j^k_0 h) = j^k_0 (gh) \). The group \( \text{Aut}_k(\mathbb{C}^m, 0) \) of jets of automorphisms act on \( \tau_{m,k} G \) by group automorphisms on the right side by composition.

For this fixed \( m \) we may take the projective limit in \( k \) and thus we obtain the pro-algebraic group \( \hat{\tau}_m G \) of formal maps from \( (\mathbb{C}^m, 0) \) to \( G \). In \( \hat{\tau}_m G \) the group of formal automorphisms \( \hat{\text{Aut}}(\mathbb{C}^m, 0) \) acts by group automorphisms on the right side by composition.

By a frame of order \( k \) at \( s \in S \) we mean a \( k \)-jet at \( 0 \in \mathbb{C}^m \) of a locally invertible map from \( (\mathbb{C}^m, 0) \) to \( (S, s) \). The frame bundle \( R^k S \to S \) is a principal bundle, modeled over the group \( \text{Aut}_k(\mathbb{C}^m, 0) \). Those bundles form a projective system and the projective limit \( R S \to S \) is the frame bundle. It is a pro-algebraic principal bundle modeled over the group \( \hat{\text{Aut}}(\mathbb{C}^m, 0) \) of formal analytic automorphisms. A section of the frame bundle is called a moving frame.

**Proposition 3.4.** Any moving frame \( \hat{\varphi} \) in \( S \) induces by composition at the right side a trivialization,

\[
\begin{align*}
J(G/S) & \xrightarrow{\hat{\varphi}^*} \hat{\tau}_m G \times S \\
& \xrightarrow{S} \hat{\tau}_m G \\
& \xrightarrow{\hat{\varphi}^*} \hat{\tau}_m G \times S \\
& \xrightarrow{\hat{\varphi}_*} J(G/S)
\end{align*}
\]

and thus a structure of principal bundle in \( \Gamma(\mathcal{D}) \),

\[
\Gamma(\mathcal{D}) \times \hat{\tau}_m G \to \Gamma(\mathcal{D}), \quad (j_x u, j_0 g) \mapsto j_x u \cdot (j_0 g \circ \hat{\varphi}_* \circ j_x \rho)
\]

**Proof.** Let \( \hat{\varphi} \) be a moving frame in \( S \). Then, for \( s \in S \) we have that \( \hat{\varphi}_s \) is a formal isomorphism between \( (\mathbb{C}^m, 0) \) and \( (S, s) \). Thus, it induces a pro-algebraic group isomorphism from \( J(G/S)_s \) to \( \hat{\tau}_m G \) that sends \( j_s g \) to \( j_0 (g \circ \hat{\varphi}_s) \). In this way we obtain the trivialization of the statement. Finally, by Proposition 3.2 and Remark 3.3 we have that the induced action of \( \hat{\tau}_m G \) in \( \Gamma(\mathcal{D}) \) gives the structure of a principal bundle.

**Remark 3.5.** Let \( \hat{\varphi} \) and \( \hat{\psi} \) be two different moving frames in \( S \). Then, there is a regular map map \( \hat{\gamma} \) from \( S \) to \( \hat{\text{Aut}}(\mathbb{C}^m, 0) \) such that \( \hat{\varphi}(s) = \hat{\psi}(s) \hat{\gamma}(s) \). We have a commutative diagram:

\[
\begin{align*}
J(G/S) & \xrightarrow{\hat{\varphi}^*} \hat{\tau}_m G \times S \\
& \xrightarrow{\hat{\psi}^*} \hat{\tau}_m G \times S \\
& \xrightarrow{\hat{\gamma} \times \text{Id}_S} \hat{\tau}_m G \times S \\
& \xrightarrow{\hat{\varphi}^*} J(G/S)
\end{align*}
\]

The group \( \hat{\text{Aut}}(\mathbb{C}^m, 0) \) acts on \( \hat{\tau}_m G \) by group automorphisms. Thus, the two \( \hat{\tau}_m G \)-principal bundle structures induced in \( \Gamma(\mathcal{D}) \) by \( \hat{\varphi} \) and \( \hat{\psi} \) are related by the fibered automorphism \( \hat{\gamma} \) of \( \hat{\tau}_m G \times S \to S \).

**Remark 3.6.** As before, our constructions are compatible with the truncation to any finite order. The moving frame \( \varphi \) induces frames of any order, and thus, also induces compatible principal bundle structures in \( \Gamma_k(\mathcal{D}) \).
modeled over $\tau_{m,k}G$ in the sense that the following diagram,

\[
\begin{array}{ccc}
\Gamma(\mathcal{D}) \times \tilde{\tau}_mG & \longrightarrow & \Gamma(\mathcal{D}) \\
\downarrow & & \downarrow \\
\Gamma_k(\mathcal{D}) \times \tau_{m,k}G & \longrightarrow & \Gamma_k(\mathcal{D})
\end{array}
\]

is commutative.

**Remark 3.7.** For $k > \ell$ there are natural surjective morphisms $\text{Iso}(\Gamma_k(\mathcal{D})) \to \text{Iso}(\Gamma_\ell(\mathcal{D}))$. The projective limit of this system yields $\text{Iso}(\Gamma(\mathcal{D}))$ which is a pro-algebraic Lie groupoid over $B$. The construction of $\text{Iso}(\Gamma_k(\mathcal{D}))$ may depend on the global frame $\tilde{\varphi}$, a map between two fibers $\Gamma(\mathcal{D})_x$ and $\Gamma(\mathcal{D})_y$ may or not be $\tilde{\tau}_mG$-equivariant for the structure induced by some global frame. However, according to Remark 3.5 if $\rho(x) = \rho(y)$, then a map between the fibers $\Gamma(\mathcal{D})_x$ and $\Gamma(\mathcal{D})_y$ is $\tilde{\tau}_mG$-equivariant for some induced structure if and only if it is $\tilde{\tau}_mG$-equivariant for any induced structure. Accordingly, the pro-algebraic Lie groupoid $\text{Iso}_S(\Gamma(\mathcal{D}))$ does not depend on the choice of the global frame in $S$.

**Example 3.8.** Our main examples are linear differential equations with parameters. Here $P = \text{GL}_k(\mathbb{C}) \times \mathbb{C}^{n+m}$, $B = \mathbb{C}^{n+m}$, and $S = \mathbb{C}^m$. We consider a linear differential system with parameters

\[(3.1) \quad \frac{\partial U}{\partial x_i} = A_iU, \quad i = 1, \ldots, n,\]

where $A_i$ are matrices with coefficients in $\mathbb{C}(x_1, \ldots, x_n, s_1, \ldots, s_m)$. The Frobenius integrability condition imposes here the compatibility equations:

\[
\frac{\partial A_i}{\partial x_j} - \frac{\partial A_j}{\partial x_i} = [A_i, A_j].
\]

Equation (3.1) can be seen itself as a sub-bundle of $J_1(P/B)$. In this case, $J_1(P/B) = \mathbb{C}^{k^2(n+m)} \times \text{GL}_k(\mathbb{C}) \times \mathbb{C}^{n+m}$, and $U_x, U_s, U, x, s$ is a system of coordinates. Equations

\[(3.2) \quad U_{x_i} - A_iU = 0, \quad i = 1, \ldots, n,\]

define $\Gamma_1(\mathcal{D})$ as a subset of $J_1(P/B)$. A basis of the space of total derivative operators is given by $\partial_{x_i}^{\text{tot}}, \partial_{s_j}^{\text{tot}}$. We differentiate equations (3.2) and obtain

\[(3.3) \quad U_{x_ix_k} - \frac{\partial A_i}{\partial x_k}U - A_jA_kU = 0,\]

\[(3.4) \quad U_{x_is_k} - \frac{\partial A_i}{\partial s_k}U - A_jU_{s_k} = 0.\]

Equations (3.2), (3.3), and (3.4) define $\Gamma_2(\mathcal{D})$, and so on. Note that $x_i, s_j, U, U_{s_j}, U_{s_js_k}, \ldots$ are coordinates on $\Gamma(\mathcal{D})$.

3.2.2. **Prolongation of $\mathcal{D}$ to $\Gamma(\mathcal{D})$.** Here we show how to lift the $G$-invariant connection $\mathcal{D}$ to a projective system of $\tau_{m,k}G$-invariant connections $\mathcal{D}^{(k)}$ in $\Gamma_k(\mathcal{D})$, and thus, a $\tilde{\tau}_mG$-invariant connection in $\Gamma(\mathcal{D})$.

**Lemma 3.9.** Let $X$ be rational vector field tangent to $\mathcal{F}$. Along $\Gamma_k(\mathcal{D})$, the total derivative $X^{\text{tot}}$ coincides with $\tilde{X}^{(k)}$, the jet prolongation of the $\mathcal{D}$-horizontal lift of $X$. Therefore $X^{\text{tot}}$ and $\tilde{X}^{(\infty)}$ coincide as derivations of $\mathcal{O}_{\Gamma(\mathcal{D})}$.

**Proof.** Let $X$ be a rational field tangent to $\mathcal{F}$. First, we have that the ideal of $\Gamma(\mathcal{D})$ is a differential ideal, so that, $X^{\text{tot}}$ defines a derivation of $\mathcal{O}_{\Gamma(\mathcal{D})}$. 
Let us fix \( j^k_x u \in \Gamma_k(\mathcal{D}) \). Let us assume that \( u \) is a \( \mathcal{D} \)-horizontal local section. The vector field \( \tilde{X} \) is tangent to the graph of \( u \). Thus, the flow of \( \tilde{X} \) leaves the section \( u \) invariant. Let us consider \( \{\sigma_t\}_{t \in \mathbb{R}} \) the local flow of \( X \) around \( x \). Then, we have,
\[
\tilde{X}^{(\infty)}(j_x u) = \left. \frac{d}{dt} \right|_{t=0} j_{\sigma_t(x)} u
\]
Thus, for any differential function \( F \) of arbitrary order, we have,
\[
(X^{\text{tot}} F)(j_x u) = X_x (F \circ j_u) = \left. \frac{d}{dt} \right|_{t=0} F(j_{\sigma_t(x)} u) = (\tilde{X}^{(\infty)} F)(j_x u).
\]
We have that \( X^{\text{tot}} \) coincides with \( \tilde{X}^{(\infty)} \) along \( \Gamma(\mathcal{D}) \), and therefore they preserve the order of differential functions.

**Example 3.10.** Let us compute \( \partial_{x_j}^{\text{tot}} \) restricted to \( \Gamma(\mathcal{D}) \) in Example 3.8. Let \( u_{ij} \) be the \((i,j)\)-entry of coordinate matrix \( U \), and \( a_{i,jk} \) be the \((j,k)\)-entry of matrix \( A_i \). The usual expression for the total derivative is:
\[
\frac{\partial}{\partial x_j}^{\text{tot}} = \frac{\partial}{\partial x_j} + u_{mk;x_j} \frac{\partial}{\partial u_{mk}} + u_{mk;x_j} u_{mk;x_t} \frac{\partial}{\partial u_{mk;x_t}} + \ldots
\]
We have that \( x_j, s_\ell, u_{mk}, u_{mk;s_\ell}, \ldots \) is a system of coordinates on \( \Gamma(\mathcal{D}) \). We obtain:
\[
\frac{\partial}{\partial x_j}^{\text{tot}} \Big|_{\Gamma(\mathcal{D})} = \frac{\partial}{\partial x_j} + a_{j,ml} u_{\ell k} \frac{\partial}{\partial u_{mk}} + \left( \frac{\partial a_{j,ml}}{\partial s_{r}} u_{\ell k} + a_{j,ml} u_{\ell k;s_r} \right) \frac{\partial}{\partial u_{mk;s_r}} + \ldots
\]
Here we see that the total derivative of a function on \( \Gamma_k(\mathcal{D}) \) is also defined on \( \Gamma_k(\mathcal{D}) \).

**Definition 3.11.** For each \( k = 1, \ldots, \infty \) we call the \( k \)-th prolongation of \( \mathcal{D} \) to the distribution \( \mathcal{D}^{(k)} \) spanned by the vector fields of the form \( X^{\text{tot}} \big|_{\Gamma_k(\mathcal{D})} \) where \( X \) is tangent to \( \mathcal{F} \).

**Remark 3.12.** The above definition ensures \( \mathcal{D}^{(k)} \) is a regular connection on \( \Gamma_k(\mathcal{D}) \). Another way of defining \( \mathcal{D}^{(k)} \) in geometrical terms is the following. Let \( u \) be a local \( \mathcal{D} \)-horizontal section defined around \( x \in B \),
\[
\mathcal{D}^{(k)}_{j^k_x u} = d(j^k u)(\mathcal{D}_x).
\]
The space \( \mathcal{D}^{(k)}_{j^k_x u} \subset T_{j^k_x u}(\Gamma_k(\mathcal{D})) \) does not depend on the choice of \( u \). It is confined into the fiber of \( \rho(x) \). Any other \( \mathcal{D} \)-horizontal section passing through the same point \( u(x) \) shall coincide with \( u \) along the fiber of \( \rho(x) \).

**Proposition 3.13.** The prolongation \( \mathcal{D}^{(k)} \) is a \( \tau_{m,k} G \)-invariant connection on \( \Gamma_k(\mathcal{D}) \) with parameters \( S \). The projection \( \Gamma_{k+1}(\mathcal{D}) \to \Gamma_k(\mathcal{D}) \) maps \( \mathcal{D}^{(k+1)} \) to \( \mathcal{D}^{(k)} \).

**Proof.** Let \( \{X_i\} \) be a commuting basis of the \( C(B) \)-space of rational vector fields tangent to \( \mathcal{F} \). Their values span \( \mathcal{F} \) on the generic point of \( B \). In virtue of Lemma 3.9 we have that \( \mathcal{D}^{(k)} \) is the distribution of vector fields spanned by \( \{ \tilde{X}_i^{(k)} \big|_{\Gamma_k(\mathcal{D})} \} \). From the compatibility of the Lie bracket and the lift of vector fields we obtain that \( \mathcal{D}^{(k)} \) is a Frobenius integrable distribution in \( \Gamma(\mathcal{D}) \). Also, from the properties of the lift we obtain that \( \mathcal{D}^{(k+1)} \) projects onto \( \mathcal{D}^{(k)} \). The invariance of \( \mathcal{D}^{(k)} \) with respect to \( \tau_{m,k} G \) follows automatically from remark 3.12.

The projective limit \( \mathcal{D}^{(\infty)} = \lim_{\rightarrow} \mathcal{D}^{(k)} \) is called the jet prolongation with respect to parameters of \( \mathcal{D} \). In virtue of Proposition 3.13 \( \mathcal{D}^{(\infty)} \) it is a \( \tau_{m} G \) invariant \( \mathcal{F} \)-connection in \( \Gamma(\mathcal{D}) \). Note that the construction of \( \mathcal{D}^{(\infty)} \) is independent of the moving frame \( \tilde{\phi} \) in \( S \) that induces the \( \tau_{m} G \)-principal bundle structure in \( \Gamma(\mathcal{D}) \). Different moving frames give different actions that are not necessarily equivalent, but at least they are equivalent along the fibers of \( \rho \).
3.3. **The parameterized Galois groupoid.** The field of rational differential invariants of order \( \leq k \) of \( \mathcal{D} \) is the field \( \mathbb{C}(\Gamma_k(\mathcal{D}))^{D(k)} \) of rational first integrals of \( \mathcal{D}^{(k)} \). We have a tower of field extensions,

\[
\mathbb{C}(S) \subset \mathbb{C}(P)^\mathcal{D} \subset \ldots \subset \mathbb{C}(\Gamma_k(\mathcal{D}))^{D(k)} \subset \mathbb{C}(\Gamma_{k+1}(\mathcal{D}))^{D(k+1)} \subset \ldots
\]

and the union of all its members is the field \( \mathbb{C}(\Gamma(\mathcal{D}))^{D(\infty)} \) of rational differential invariants of \( \mathcal{D} \). If \( X \) is a rational vector field in \( B \) and \( f \) a rational invariant of \( \mathcal{D} \) of order \( \leq k \) then \( X^{\text{tot}} f \) is a rational invariant of \( \mathcal{D} \) of order \( \leq k + 1 \). Thus, we have that \( \mathbb{C}(\Gamma(\mathcal{D}))^{D(\infty)} \) is a differential field with derivations \( \mathcal{X}(B)^{\text{tot}} \).

Moreover, by the finiteness of differential subfields (for instance, by Theorem 14 in [Kol73], p. 112) we have that there is some \( \ell \) such that the field of differential invariants is spanned by \( \mathbb{C}(\Gamma_{\ell}(\mathcal{D}))^{D(\ell)} \) and total differentiation.

Now let us translate, by means of the Galois correspondence 2.27, this tower of fields into a system of groupoids, and the field of rational differential invariants into a pro-algebraic groupoid.

In order to have a principal structure in \( \Gamma(\mathcal{D}) \) we need to take a moving frame on \( S \). It is well known that there always exists a rational moving frame on \( S \). We may, for instance, take the frame induced by a transcendence basis of \( \mathbb{C}(S) \). Thus, we fix a global frame \( \hat{\varphi} \) in \( S \), that we assume to be regular, after restriction to a suitable affine open subset.

**Lemma 3.14.** The Galois groupoid \( \text{GGal}(\mathcal{D}^{(k)}) \) does not depend on the choice of the moving frame \( \hat{\varphi} \) on \( S \).

**Proof.** Let \( \hat{\varphi} \) and \( \hat{\psi} \) two different moving frames on \( S \), whose truncations to order \( k \) induce respective \( \tau_{m,k} \)-structures in \( \Gamma_k(\mathcal{D}) \rightarrow B \). Thus, there are two different groupoids of gauge automorphisms \( \text{Iso}^\hat{\varphi}(\Gamma_k(\mathcal{D})) \) and \( \text{Iso}^\hat{\psi}(\Gamma_k(\mathcal{D})) \). However, by Remark 3.7 we have \( \text{Iso}_S(\Gamma_k(\mathcal{D})) \subset \text{Iso}^\hat{\varphi}(\Gamma_k(\mathcal{D})) \cap \text{Iso}^\hat{\psi}(\Gamma_k(\mathcal{D})) \). We also have \( \mathbb{C}(S) \subset \mathbb{C}(\Gamma_k(\mathcal{D}))^{D(k)} \). By Galois correspondence 2.27 we have that the Galois groupoid of \( \mathcal{D}^{(k)} \) is inside \( \text{Iso}_S(\Gamma_k(\mathcal{D})) \), hence independent of the choice of the global frame. \( \square \)

**Definition 3.15.** Let us consider \( \mathcal{D} \) a principal \( G \)-invariant connection on \( P \) with parameters in \( S \).

1. The Galois groupoid (and group bundle) of order \( k \) with parameters of \( \mathcal{D} \) is the Galois groupoid (and group bundle) of gauge automorphisms of \( \Gamma_k(\mathcal{D}) \) that fixes rational differential invariants of \( \mathcal{D} \) of order \( \leq k \).

\[
\text{PGal}_k(\mathcal{D}) = \text{GGal}(\mathcal{D}^{(k)}), \quad \text{Gal}_k(\mathcal{D}) = \text{Gal}(\mathcal{D}^{(k)}).
\]

2. The Galois groupoid with parameters of \( \mathcal{D} \) is the groupoid of gauge automorphisms of \( \Gamma(\mathcal{D}) \) that fixes rational differential invariants of \( \mathcal{D} \).

\[
\text{PGal}_\infty(\mathcal{D}) = \lim_{k \to \infty} \text{GGal}(\mathcal{D}^{(k)})
\]

3. The Galois group with parameters of \( \mathcal{D} \) is the diagonal part of the Galois groupoid with parameters of \( \mathcal{D} \),

\[
\text{Gal}_\infty(\mathcal{D}) = \text{PGal}_\infty(\mathcal{D})^{\text{diag}}
\]

3.4. **Differential structure of the** \( \text{Gau}(\Gamma(\mathcal{D})) \). The Galois group with parameters, as in Definition 3.15, is rational subgroup bundle of \( \text{Gau}(\Gamma(\mathcal{D})) \). In what follows we present its natural differential group structure.

The fibers of \( J(P/B) \rightarrow B \) are principal homogeneous spaces for the fibers of the group bundle \( J(G/B) \rightarrow B \) (see 3.1.3). We can consider the bundle \( \text{Gau}(J(P/B)) \rightarrow B \) of gauge automorphisms as the quotient \( (J(P/B) \times_B J(P/B))/J(G/B) \). This quotient exists as a pro-algebraic variety (at least on the generic point of \( B \)); it can be constructed, for instance, trivializing the group bundle \( J(G/B) \rightarrow B \) by means of a moving frame in \( B \).

**Lemma 3.16.** Let \( E \rightarrow B \) be a fiber bundle and \( G \) an algebraic group acting on \( E \) and preserving the projection to \( B \). Assume \( E/G \) exists as smooth algebraic variety. Then there is a canonical isomorphism \( J(E/B)/J(G/B) \simeq J((E/G)/B) \) of bundles over \( B \).
Proof. Let $f$ be the projection $E \to E/G$ and $j f$ the induced map $J(E/G) \to J((E/G)/B)$. Because $j f(j x) = x(f(x))$, this maps induces the wanted isomorphism.

**Proposition 3.17.** For the principal bundle $π: P \to B$ there is a canonical isomorphism $\text{Gau}(J(P/B)) \simeq J(\text{Gau}(P)/B)$ of bundles over $B$.

*Proof.* It suffices to consider the case $E = P \times_B P$ in Lemma 3.16.

From this, we know that $\text{Gau}(J(P/B))$ has a structure of differential algebraic group. Let us consider now the bundle of jets of $D$-horizontal sections $Γ(D) \subset J(P/B)$. It is a differential subvariety of $J(P/B)$ in the sense that it is the zero locus of the differential ideal $E(D) \subset O(J(P/B))$ (see Subsection 3.2).

**Theorem 3.18.** The group bundle of gauge automorphisms $Γ(D)$ is identified with the differential algebraic subgroup of gauge symmetries of $D$, defined by the group connection $\text{Adj}(D)$.

*Proof.* The differential subvariety $Γ(D) \subset J(P/B)$ is principal for the action of the subgroup bundle $J(G/S) \times B \subset J(G/B)$ (note that two $D$-horizontal sections are related by a right translation which is constant along the fibers of $ρ$), this being a differential algebraic subgroup of $J(G/B)$.

By means of the general construction of $\text{Gau}(P) = (P \times_B P)/G$ and Proposition 3.17 we have a commutative diagram

$$
\begin{array}{ccc}
Γ(D) \times_B Γ(D) & \longrightarrow & J(P/B) \times J(P/B) \\
\downarrow & & \downarrow \\
\text{Gau}(Γ(D)) & \longrightarrow & J(\text{Gau}(P)/B)
\end{array}
$$

It is clear that if a pair $(j_x u, j_x v)$ of jets of $D$-horizontal sections are related by an element of $J(G/B)_x$, then this element is constant along the fibers of $ρ$. Therefore, the map $i$ is injective. Finally, an element $j_x σ \in J(\text{Gau}(P)/B)$ is in the image of $i$ if and only if it transform $D$-horizontal sections into $D$-horizontal sections, if and only if it is a jet of a gauge symmetry of $D$, if and only if it is $\text{Adj}(D)$-horizontal.

**Remark 3.19.** The action of $\text{Gau}(Γ(D))$ on $Γ(D)$ is, by definition, compatible with the differential structure, in the sense that the co-action:

$$α^*: O_Γ(D) \to O_{\text{Gau}(Γ(D))} \otimes C(B) O_Γ(D)$$

is compatible with the total derivative operators.

**Theorem 3.20.** The parameterized Galois group bundle $\text{Gal}_∞(D)$ is a differential algebraic subgroup of $J(\text{Gau}(P)/B)$.

*Proof.* Let us compute de equations of $\text{Gal}_∞(D)$ inside $\text{Gau}(Γ(D))$ in order to verify that it is the zero locus of a differential Hopf ideal in $O_{\text{Gau}(Γ(D))}$. From the group bundle structure we already know that the ideal of $\text{Gal}_∞(D)$ is a Hopf ideal; it suffices to check that it is a differential ideal.

By definition, $\text{Gal}_∞(D)$ is the group of gauge automorphisms commuting with rational differential invariants $C(Γ(D))^{D(∞)}$. This field is differentially finitely generated over $C(S)$, let us take a system of generators.

$$C(Γ(D))^{D(∞)} = C(S)⟨h_1, \ldots, h_k⟩$$

There is some $N$ big enough such that the differential functions $h_i$ belong to $C(Γ_N(D))$. By construction (and restricting our considerations to a suitable open subset of $B$) $Γ_N(D)$ is an affine algebraic variety, so that we have,

$$h_i = \frac{P_i}{Q_i}$$
with \( P_i, Q_i \) in \( O_{\Gamma(D)} \). Now, we define
\[
F_i = \alpha^*(P_i)(1 \otimes Q_i) - \alpha^*(Q_i)(1 \otimes P_i)
\]
which are elements of \( O_{\text{Gau}(\Gamma(D))} \otimes_{\mathbb{C}(B)} O_{\Gamma(D)} \). We consider \( \mathcal{I} \) the radical differential ideal \( \{ F_1, \ldots, F_k \} \).

From Remark 3.19 we have that the zero locus of \( \mathcal{I} \) is \( \text{Gal}_\infty(D) \times_B \Gamma(D) \). Therefore, the ideal of the Galois group bundle is the differential-Hopf ideal \( \mathcal{I}^*(\mathcal{I}) \) for the canonical inclusion \( \mathcal{I}^* : O_{\text{Gau}(\Gamma(D))} \to O_{\text{Gau}(\Gamma(D))} \otimes_{\mathbb{C}(B)} O_{\Gamma(D)} \).

3.5. Isomonodromic deformations. An isomonodromic deformation of the connection \( D \) with parameters in \( S \) is a partial \( G \)-invariant connection \( \tilde{D} \) extending \( D \). If we take \( \tilde{F} = \pi_*(\tilde{D}) \), then \( \tilde{D} \) is a partial \( \tilde{F} \)-connection. Paths along the leaves of \( \rho_*(\tilde{F}) \) are called isomonodromic paths. The main application is that the monodromy representation of the connection with parameters is constant (up to conjugation) along isomonodromic paths.

Remark 3.21. In the analytic context, the restriction of \( D \) to a leaf of \( \tilde{F} \) is an isomonodromic family. Under some assumptions we have that \( D \) is an isomonodromic family if and only if it admits an isomonodromic deformation which is a \( TB \)-connection (see [CS06] §5 and references therein).

An important point about isomonodromic deformations is that they give us first order equations for the Galois group with parameters. The following lemma is a generalization (in our geometrical setting) of Proposition 5.4 in [CS06].

**Lemma 3.22.** If \( \tilde{D} \) is an isomonodromic deformation of \( D \), then \( \text{Gal}_\infty(D) \subset \Gamma(\text{Adj}(\tilde{D})) \).

**Proof.** It suffices to verify that \( \text{Gal}_k(D) \subset \Gamma_k(\text{Adj}(\tilde{D})) \) for any finite \( k \). Any \( \tilde{D} \)-horizontal section is, in particular, \( D \)-horizontal. It follows that \( \Gamma_k(\tilde{D}) \subset \Gamma_k(D) \).

Let us consider a moving frame in \( S \), so that we may make use of the \( \tau_{m,k}G \)-structure in \( \Gamma(D) \). From the construction of the prolongation \( D^{(k)} \) we have that for any \( j^k u \in \Gamma_k(\tilde{D}) \) there is an inclusion of vector spaces \( D^{(k)}_{j^k u} \subset D^{(k)}_{j^k u} \). Therefore \( \Gamma_k(\tilde{D}) \) is tangent to the distribution \( D^{(k)} \). It is in fact a reduction of structure group to \( \tau_{m-d,k}G \), where \( d \) is the codimension of \( D \) in \( \tilde{D} \).

From there, we have that \( \text{Iso}(\Gamma_k(\tilde{D})) \) is a subgroupoid of \( \text{Iso}(\Gamma_k(D)) \) and it is tangent to the distribution \( D^{(k)} \otimes D^{(k)} \), as defined in Remark 2.24. From the topological construction of the Galois groupoid (see Remark 2.25) we have \( G \text{Gal}(D^{(k)}) \subset \text{Iso}(\Gamma_k(\tilde{D})) \). Now, by taking the diagonal parts we have \( \text{Gal}_k(D) \subset \Gamma_k(\text{Adj}(\tilde{D})) \).

Theorems A.9 and A.11 describe all Zariski dense differential subgroups \( H \) of \( J(\text{Gau}(P)/B) \) for simple algebraic group \( G \). There exists a unique partial \( G \)-invariant connection \( \tilde{D} \) such that \( H = \Gamma(\text{Adj}(\tilde{D})) \). Note that \( \text{Gal}_\infty(D) \) is Zariski dense in \( J(\text{Gau}(P)/B) \) if and only if \( \text{Gal}(D) = \text{Gau}(P) \). We can state our main result.

**Theorem 3.23.** Let \( P \to B \) be an affine principal bundle with simple group \( G \), \( \rho : B \to S \) a dominant map, \( \mathcal{F} = \ker(d\rho) \), and \( D \) a principal \( G \)-invariant connection with parameters in \( S \). Let us assume that the Galois group of \( D \) is \( \text{Gau}(P) \). Then, there is a biggest isomonodromic deformation \( \tilde{D} \) of \( D \) and the Galois group with parameters \( \text{Gal}_\infty(D) \) is the group \( \Gamma(\text{Adj}(\tilde{D})) \) of gauge symmetries of \( \tilde{D} \).

**Proof.** From Lemma 3.22 and Theorem A.9 it is clear that the Galois group with parameters is the group of gauge symmetries of a certain isomonodromic deformation \( \tilde{D} \) of \( D \). It suffices to check that any other isomonodromic deformation is extended by \( \tilde{D} \). Let \( D_1 \) be an isomonodromic deformation of \( D \). By Lemma 3.22 we have \( \text{Gal}_\infty(D) = \Gamma(\text{Adj}(\tilde{D})) \subset \Gamma(\text{Adj}(D_1)) \). From there, and Theorem A.11 we have \( D_1 \subset \tilde{D} \). □
Example 3.24. Let us consider $B = \mathbb{C}^{k+1} \times \mathfrak{sl}_n(\mathbb{C})^k$ with coordinates $x, a_1, \ldots, a_k, A_1, \ldots, A_k$; $S = \mathbb{C}^k \times \mathfrak{sl}_n(\mathbb{C})^k$ with the obvious projection (forgetting the coordinate $x$), and $P = \text{SL}_n(\mathbb{C}) \times B$. The general Fuchsian system with $k$ singularities and trace free matrices,

\begin{equation}
\frac{\partial U}{\partial x} = \left( \sum_{i=1}^{n} \frac{A_i}{x - a_i} \right) U
\end{equation}

is a $\text{SL}_n(\mathbb{C})$-invariant connection $\mathcal{D}$ on $P$ with parameters in $S$. The general isomonodromic deformation (see, for instance, [IKSY13] §3.5) admitted by (3.5) is the well-known Schlessinger system. It consists in the system of equations formed by (3.5) together with:

\begin{align}
\frac{\partial A_i}{\partial a_j} &= \frac{[A_i, A_j]}{\lambda_i - \lambda_j} \\
\frac{\partial A_i}{\partial a_i} &= - \sum_{i \neq j} \frac{[A_i, A_j]}{\lambda_i - \lambda_j} \\
\frac{\partial U}{\partial a_i} &= \frac{A_i}{x - a_i} U.
\end{align}

Equations (3.6), (3.7) define the foliation $\rho_\ast(\mathcal{F})$ of isomonodromic paths in $S$, and equations (3.5) - (3.8) define the isomonodromic deformation $\mathcal{D}$ as a partial $\mathcal{F}$-connection. Thus, the Galois group with parameters of [3.5] is the differential algebraic subgroup of $J(\text{SL}_n(\mathbb{C})/B)$ given by equations (3.6), (3.7), and

\begin{align}
\frac{\partial \sigma}{\partial x} &= \left[ \sum_{i=1}^{n} \frac{A_i}{x - a_i}, \sigma \right] \\
\frac{\partial \sigma}{\partial a_i} &= \left[ \frac{A_i}{x - a_i}, \sigma \right].
\end{align}

4. GAUSS HYPERGEOMETRIC EQUATION.

Let us consider Gauss hypergeometric equation:

\begin{equation}
x(1-x)\frac{d^2 u}{dx^2} + \{ \gamma - (\alpha + \beta + 1)x \} \frac{du}{dx} - \alpha \beta u = 0
\end{equation}

We see equation (4.1) as a linear connection with parameters in the following way. We set $P = \text{GL}_2(\mathbb{C}) \times B$, $B = \mathbb{C}_x \times S$ and $S = \mathbb{C}_x^3$ with the obvious projections. Then, the hypergeometric equation is the $\text{GL}_2(\mathbb{C})$-invariant partial connection $\mathcal{H}$ in $P$ defined by the differential system:

\begin{equation}
d \begin{pmatrix} u_{11} & u_{12} \\
 u_{21} & u_{22} \end{pmatrix} = \begin{pmatrix} 0 & \frac{\alpha \beta}{x(1-x)} \\
 \frac{(\alpha+\beta+1)x - \gamma}{x(1-x)} & 1 \end{pmatrix} \begin{pmatrix} u_{11} & u_{12} \\
 u_{21} & u_{22} \end{pmatrix} = 0, \quad d\alpha = 0, \quad d\beta = 0, \quad d\gamma = 0.
\end{equation}

4.1. Projective reduction. Let us set $P_{\text{proj}} = \text{PGL}_2(\mathbb{C}) \times B$. There is a canonical quotient map $P \to P_{\text{proj}}$ which is a morphism of principal bundles. The projection of $\mathcal{H}$ is a $\text{PGL}_2(\mathbb{C})$-invariant partial connection $\mathcal{H}_{\text{proj}}$ on $P_{\text{proj}}$. This connection has a nice geometric interpretation. Let us consider $J^2_2(\mathbb{C}^1, \mathbb{P}_1)$ the space of 2-jets of local diffeomorphisms from $\mathbb{C}^1$ to $\mathbb{P}_1$. Let us choose an affine embedding $\varphi$ of $\mathbb{C}_1$ in $\mathbb{P}_1$, for instance $\varphi(\varepsilon) = [\varepsilon : 1]$. Let us consider the action of $\text{PGL}_2(\mathbb{C})$ in $\mathbb{P}_1$ on the right side, by setting:

\begin{equation}
[t_0 : t_1] \star \begin{pmatrix} a \\
 c \end{pmatrix} = [at_0 + ct_1 : bt_0 + dt_1].
\end{equation}

We get an isomorphism of $\text{PGL}_2(\mathbb{C})$ bundles,

$P_{\text{proj}} \to J^2_2(\mathbb{C}, \mathbb{P}_1) \times \mathbb{C}_x^3$, \quad $(\sigma, x, \alpha, \beta, \gamma) \mapsto (j^2_2(\varphi \ast \sigma), \alpha, \beta, \gamma)$. 

Through such isomorphism, the reduced connection is seen as a third order differential equation in the projective space, the well known Schwartzian equation: if \( \{ u_1, u_2 \} \) is a local basis of solutions of (4.1) then \( y = \frac{u_1}{u_2} \) satisfies,

\[
\text{Schw}_x(y) = \nu(\alpha, \beta, \gamma; x),
\]

with

\[
\nu(\alpha, \beta, \gamma; x) = \frac{\gamma(2 - \gamma)}{4x^2} + \frac{1 - (\gamma - \alpha - \beta)^2}{4(1 - x^2)} + \frac{\gamma(1 - \gamma + \alpha + \beta - 2\alpha\beta)}{2x(1 - x)}.
\]

**Lemma 4.1.** For very general values of \( (\alpha, \beta, \gamma) \in S \) there is no smooth isomonodromic path of \( H_{\text{proj}} \) passing through \( (\alpha, \beta, \gamma) \).

**Proof.** Here we apply the description of the monodromy of (4.1) in terms of the parameters, as explained in [IKSY13]. The eigenvalues of the monodromy matrices at 0, 1, \( \infty \) are respectively \( \{ 1, e^{-2\gamma\pi i}, e^{2(\gamma - \alpha - \beta)\pi i} \} \). The transcendental functions,

\[
f = e^{2\gamma\pi i} + e^{-2\gamma\pi i}, \quad g = e^{2(\gamma - \alpha - \beta)\pi i} + e^{2(\alpha + \beta - \gamma)\pi i}, \quad h = e^{2(\alpha - \beta)\pi i} + e^{2(\beta - \alpha)\pi i},
\]

are, by construction, invariants of the monodromy of \( H_{\text{proj}} \). Thus, they are constant along any isomonodromic path. A simple calculus shows that they are functionally independent on the very general point of \( S \). It yields the result. \( \square \)

**Corollary 4.2.** The differential Galois group with parameters of \( H_{\text{proj}} \) consists in all the gauge symmetries \( \Gamma(\mathcal{H}_{\text{proj}}) \).

**Proof.** It is a direct consequence of Lemma 4.1 and Theorem 3.23. \( \square \)

4.2. **Differential equation for the determinant.** Another reduction of (4.1) is given by the quotient map

\[
P \to P_{\text{det}} = \mathbb{C}^* \times B, (U, x, \alpha, \beta, \gamma) \mapsto (w = \det(U), x, \alpha, \beta, \gamma).
\]

The projection is a morphism of principal bundles and it sends \( H \) to a partial connection \( H_{\text{det}} \) in \( P_{\text{det}} \) defined by the differential system:

\[
dw - \frac{(\alpha + \beta + 1)x - \gamma}{x(1 - x)}wdx = 0, \quad d\alpha = 0, \quad d\beta = 0, \quad d\gamma = 0.
\]

It is convenient to consider an affine change of variables in the parameter space, by setting:

\[
a = -\gamma, \quad b = \alpha + \beta - \gamma + 1, \quad c = \alpha
\]

The equation for horizontal sections of \( H_{\text{det}} \) is now written as:

\[
\frac{dw}{dx} = \left( \frac{a}{x} - \frac{b}{1 - x} \right)w.
\]

And its general solution is:

\[
w = f(a, b, c)x^a(1 - x)^b.
\]

Let us compute the Galois group with parameters of such equation. Note that

\[
\mathbb{C}(\Gamma(\mathcal{H}_{\text{det}})) = \mathbb{C}(x, a, b, c, w, w_\alpha, w_\beta, w_\gamma, w_{\alpha a}, \ldots) = \mathbb{C}(x, a, b, c)(w).
\]

Parameter \( c \) does not appear on the equation. This means that in the \( \mathbb{C}(\Gamma(\mathcal{H}_{\text{det}})) \) the differential function \( w_c \) is an invariant. Thus,

\[
\mathbb{C}(w) \subset \mathbb{C}(\Gamma(\mathcal{H}_{\text{det}}))^{\mathcal{H}_{\text{det}}^\infty}.
\]
For the rest of the computation let us ignore the derivatives w.r.t. the parameter \( c \) and let us consider the equation as dependent only of parameters \( a \) and \( b \). This is equivalent to projecting the equation onto a quotient basis \( B' \). Let us consider the equation for the second prolongation \( \mathcal{H}_{\text{det}}^{(2)} \). It is:

\[
\begin{align*}
    w_x &= \left( \frac{a}{x} - \frac{b}{1-x} \right) w \\
    w_{ax} &= \frac{1}{x} w + \left( \frac{a}{x} - \frac{b}{1-x} \right) w_a \\
    w_{bx} &= \frac{1}{1-x} w + \left( \frac{a}{x} - \frac{b}{1-x} \right) w_b \\
    w_{aax} &= \frac{2}{x} w_a + \left( \frac{a}{x} - \frac{b}{1-x} \right) w_{aa} \\
    w_{abx} &= \frac{1}{1-x} w_a + \frac{1}{x} w_b + \left( \frac{a}{x} - \frac{b}{1-x} \right) w_{ab} \\
    w_{bbx} &= \frac{2}{1-x} w_b + \left( \frac{a}{x} - \frac{b}{1-x} \right) w_{bb}
\end{align*}
\]

At this level, they appear three rational first integrals of \( \mathcal{H}_{\text{det}}^{(2)} \), namely:

\[
\begin{align*}
    R &= \frac{w_{aa}}{w} - \frac{w_a^2}{w^2}, \quad S = \frac{w_{ab}}{w} - \frac{w_a w_b}{w^2}, \quad T = \frac{w_{bb}}{w} - \frac{w_b^2}{w^2}.
\end{align*}
\]

Thus, \( \mathbb{C}(\Gamma(\mathcal{H}_{\text{det}}))^{\mathcal{H}_{\text{det}}^\infty} \) contains the \( \mathbb{C}^* \)-invariant \( \mathcal{X}(B)_{\text{tot}} \)-differential field spanned by \( w, R, S \) and \( T \).

Let us compute the differential \( B \)-group associated to this field.

The gauge group \( J(Gau(P/B)) \) is in this case isomorphic \( J(B, \mathbb{C}^*) \). On the other hand, we have that the adjoint equation in dimension 1 vanish, so we also have \( \sigma_x = 0 \). From the rational invariants we have that the equations for the Galois group \( \text{Gal}_{\infty}(\mathcal{H}_{\text{det}}) \) should include:

\[
\sigma_x = 0, \quad \sigma_c = 0, \quad \sigma_{aa} = \frac{\sigma_a^2}{\sigma}, \quad \sigma_{ab} = \frac{\sigma_a \sigma_b}{\sigma}, \quad \sigma_{bb} = \frac{\sigma_b^2}{\sigma}.
\]

The three last equations are equivalent to say that \( \sigma \) has constant logarithmic derivative with respect to \( a \) and \( b \). So, these equations define a differential algebraic group, which is in fact a group bundle with fibers of dimension 3 over \( B \).

\[
\mathcal{G} = \{ j_p \sigma : \sigma_x = \sigma_c = \partial_a(\sigma_a/\sigma) = \partial_b(\sigma_a/\sigma) = \partial_b(\sigma_b/\sigma) = 0 \}.
\]

Let us observe that,

\[
\mathcal{G} \simeq \ldots \simeq \mathcal{G}_k \simeq \ldots \simeq \mathcal{G}_3 \simeq \mathcal{G}_2 \simeq \mathcal{G}_1 \to B.
\]

Let us see that the Galois group is exactly this group.

**Lemma 4.3.** Let us fix \( a \) and \( b \) complex numbers \( \mathbb{Q} \)-linearly independent. Let us consider the differential system with coefficients in \( \mathbb{C}(x) \):

\[
\frac{d}{dx} \begin{pmatrix} w_0 \\ w_1 \\ w_2 \end{pmatrix} = \begin{pmatrix} \frac{a}{x} - \frac{b}{1-x} & 0 & 0 \\ \frac{a}{x} & \frac{b}{1-x} & 0 \\ \frac{a}{x} - \frac{b}{1-x} & \frac{a}{x} & \frac{b}{1-x} \end{pmatrix} \begin{pmatrix} w_0 \\ w_1 \\ w_2 \end{pmatrix}
\]

Its Galois group is a connected group of dimension 3.
Proof. A fundamental matrix of solutions:
\[
\begin{pmatrix}
x^a(1-x)^b & 0 & 0 \\
\log(x)x^a(1-x)^b & x^a(1-x)^b & 0 \\
\log(1-x)x^a(1-x)^b & 0 & x^a(1-x)^b \\
\end{pmatrix}.
\]
We may compute its monodromy group. For rationally independent \(a\) and \(b\) its Zariski closure is connected group of dimension 3.

We have that \(\text{Gal}_1(\mathcal{H}_{det}^{(1)}(x,a,b,c))\) must contain the monodromy at \((x,a,b,c)\) of the connection \(P_{\text{det}}\). By Lemma 4.3 we have that the Zariski closure of the monodromy on \((x,a,b,c)\) contains \(\mathcal{G}_{1,(x,a,b,c)}\). Therefore we have:
\[\text{Gal}_1(\mathcal{H}_{det}^{(1)}(x,a,b,c)) \subset \mathcal{G}_{1,(x,a,b,c)} \subset \text{Gal}_1(\mathcal{H}_{det}^{(1)}(x,a,b,c)).\]
Thus, we have the equality. The equations of the Galois group can be easily integrated, so be obtain a description of the functions whose jets are elements of \(\text{Gal}_\infty(\mathcal{H}_{det})\).

Proposition 4.4. The differential Galois group with parameters of \(\mathcal{H}_{det}\) is,
\[\text{Gal}_\infty(\mathcal{H}_{det}) = \{j_{(x_0,a_0,b_0,\gamma_0)} : \sigma(x,a,b,c) = \exp(\mu_0 + \mu_1 \gamma + \mu_2 (\alpha + \beta)) \mid \mu_0, \mu_1, \mu_2 \in \mathbb{C}\}.\]
which is the set of differential zeroes of the Hopf differential ideal,
\[\left\{\partial_x \sigma, \partial_c \sigma, \partial_a \frac{\partial_a \sigma}{\sigma}, \partial_a \frac{\partial_b \sigma}{\sigma}, \partial_b \frac{\partial_b \sigma}{\sigma}\right\} \subset \mathcal{O}_J(\mathbb{C}/B),\]
where,
\[
\begin{align*}
\partial_a &= -\partial_b - \partial_\gamma, \\
\partial_b &= \partial_\beta, \\
\partial_c &= \partial_\alpha - \partial_\beta.
\end{align*}
\]

4.3. Computation of the Galois group. We have a 2-covering group morphism,
\[\varphi : \text{GL}_2(\mathbb{C}) \to \text{PGL}_2(\mathbb{C}) \times \mathbb{C}^*, \; A \mapsto ([A], \text{det}(A)).\]
Its kernel of is \([-1,1]\). Let us set \(G_{\text{red}} = \text{GL}_2(\mathbb{C})/\{-1,1\}\), \(P_{\text{red}} = P/\{-1,1\}\). So \(P_{\text{red}}\) is \(G_{\text{red}}\)-principal bundle. The hypergeometric distribution \(\mathcal{H}\) induces \(\mathcal{H}_{\text{red}}\) in \(P_{\text{red}}\).

We have an isomorphism,
\[\psi : P_{\text{red}} \sim \to P_{\text{proj}} \times_B P_{\text{det}},\]
that yield us a decoupling \(\psi_\ast(\mathcal{H}_{\text{red}}) = \mathcal{H}_{\text{proj}} \times_B \mathcal{H}_{\text{det}}\). From the commutation of direct products and jets, we have that \(\text{Gal}_\infty(\mathcal{H}_{\text{red}})\) is a differential algebraic subgroup of \(\text{Gal}_\infty(\mathcal{H}_{\text{proj}}) \times_B \text{Gal}_\infty(\mathcal{H}_{\text{det}})\) that projects surjectively onto both components. We will make use of the following.

Lemma 4.5. Let \(G\) be a simple algebraic group and \(B\) an algebraic variety. \(J(G/B)\) is simple as differential algebraic group.

Proof. Let \(H \triangleleft J(G/B)\) be a differential algebraic subgroup. Then \(H_0\) is rational group subbundle of \(G \times B \to B\), therefore either \(H_0 = G \times B\) or \(H_0 = \{\text{Id}\} \times B\). In the latter case \(H\) is the identity subgroup bundle \(J(G/B)\). In the former case, by Theorem \[A.9\] we have \(H = \Gamma(\mathcal{E})\) for a singular foliation \(\mathcal{F}\) on \(B\) and a group \(\mathcal{F}\)-connection \(\mathcal{E}\).

Let us recall the classical decomposition of the tangent group \(TG \simeq \text{Lie}(G) \times G\). Let us fix \(x\) a regular point of \(\mathcal{F}\). The 1-jet at \(x\) of a function from \(B\) to \(G\) can be identified with its derivative which is a linear map from \(T_xB\) to a fiber of \(TG \to G\). Therefore we have semidirect product decomposition,
\[J_1(G/B)_x \simeq \text{Lin}_C(T_xB, \text{Lie}(G)) \times G.\]
On the other hand, let us consider $\mathcal{L}$ the leaf of $\mathcal{F}$ that passes through $x$. The same argument applies, so we have

$$J_1(G/\mathcal{L})_x \cong \text{Lin}_\mathbb{C}(\mathcal{F}_x, \text{Lie}(G)) \rtimes G.$$  

The value of the group $\mathcal{F}$-connection $\mathcal{C}$ at $x$ can be seen as a section $\mathcal{C}_x$ from $G$ to $J_1(G/\mathcal{L})_x$ that assigns to any initial condition $g$ in $G$ the only $\mathcal{C}$-horizontal leaf that passes through $(x, g)$. In the following diagram, where $\pi_x$ is the restriction to the leaf $\mathcal{L}$, we have $H_{1,x} = \pi_x^{-1}(\mathcal{C}_x(G))$.

\[
\begin{array}{ccc}
0 & \longrightarrow & \text{Lin}_\mathbb{C}(T_x B, \text{Lie}(G)) \\
\downarrow & & \downarrow \pi_x \\
0 & \longrightarrow & J_1(G/\mathcal{L})_x \\
\end{array}
\]

\[
\begin{array}{ccc}
J_1(G/\mathcal{L})_x & \longrightarrow & G \\
\downarrow \pi_x & & \downarrow \text{Id} \\
J_1(G/\mathcal{L})_x & \longrightarrow & G \\
\end{array}
\]

If $H_{1,x} \subset J_1(G/B)_x$ then $\mathcal{C}_x(G) \leq J_1(G/\mathcal{L})_x$. However, this would produce an isomorphic direct product decomposition $J_1(G/\mathcal{L})_x \cong \text{Lin}(\mathcal{F}_x, \text{Lie}(G)) \times G$, which does not exist as the adjoint representation is not trivial. Hence, $H_{1,x}$ is not a normal subgroup, except in the case in which $\mathcal{F}$ is the foliation by points. □

**Lemma 4.6.** $\text{Gal}_\infty(\mathcal{H}_{\text{red}}) = \text{Gal}_\infty(\mathcal{H}_{\text{proj}}) \times_B \text{Gal}_\infty(\mathcal{H}_{\text{det}})$

**Proof.** Here we follow a reasoning of Kolchin [Kol68]. Consider the projections $\pi_{\text{proj}} : \text{Gal}_\infty(\mathcal{H}_{\text{red}}) \rightarrow \text{Gal}_\infty(\mathcal{H}_{\text{proj}})$ and $\pi_{\text{det}} : \text{Gal}_\infty(\mathcal{H}_{\text{red}}) \rightarrow \text{Gal}_\infty(\mathcal{H}_{\text{det}})$. The kernel of $\pi_{\text{red}}$ is a differential algebraic group of the form,

$$\ker(\pi_{\text{proj}}) = \text{Id} \times_B K_{\text{det}}$$

where $K_{\text{det}}$ is a differential algebraic subgroup of $\text{Gal}_\infty(\mathcal{H}_{\text{det}})$. Moreover, for generic $p \in B$ and any order $k$ we have $K_{k,p}^{\text{det}}$ is a normal algebraic subgroup of $\text{Gal}_k(\mathcal{H}_{\text{det}})$. For the same reason we have that the kernel of $\pi_{\text{proj}}$ is a differential algebraic group of the form,

$$\ker(\pi_{\text{proj}}) = K_{\text{proj}} \times_B \text{Id}$$

where $K_{\text{proj}}$ is a differential algebraic subgroup of $\text{Gal}_\infty(\mathcal{H}_{\text{det}})$. Moreover, for generic $p \in B$ and any order $k$ we have $K_{k,p}^{\text{proj}}$ is a normal algebraic subgroup of $\text{Gal}_k(\mathcal{H}_{\text{proj}})$. The subgroup $\text{Gal}_k(\mathcal{H})_p$ gives the graph of an algebraic group isomorphism,

$$\text{Gal}_k(\mathcal{H})_p / K_{k,p}^{\text{proj}} \cong \text{Gal}_k(\mathcal{H})_p / K_{k,p}^{\text{det}}$$

Therefore, the quotient $\text{Gal}_k(\mathcal{H})_p / K_{k,p}^{\text{proj}}$ is for any $k$ an abelian group of dimension smaller or equal than three. By Lemma 4.5 the only possibility is $\text{Gal}_k(\mathcal{H})_p = K_{k,p}^{\text{proj}}$. This is for generic $p$ and all $k$, therefore $\text{Gal}_\infty(\mathcal{H})_p = K_{\text{proj}}$ and it follows the required statement. □

The quotient map $\pi_{\text{red}} : P \rightarrow P_{\text{red}}$ induces a 2-covering group bundle morphism $\pi_{\text{red}*} : \text{Gau}(\Gamma(\mathcal{H})) \rightarrow \text{Gau}(\Gamma(\mathcal{H}_{\text{red}}))$, whose restriction to the Galois group bundles gives a surjective map $\pi_{\text{red}} : \text{Gal}_\infty(\mathcal{H}) \rightarrow \text{Gal}_\infty(\mathcal{H}_{\text{red}})$. This morphism may be either an isomorphism or a 2-covering. It turns out that $\pi_{\text{red}}^{-1}(\text{Gal}_\infty(\mathcal{H}_{\text{red}}))$ is connected, and the smallest differential algebraic subgroup of $\text{Gau}(\Gamma(\mathcal{H}))$ that projects surjectively onto $\text{Gal}_\infty(\mathcal{H}_{\text{red}})$. Therefore,

$$\text{Gal}_\infty(\mathcal{H}) = \pi_{\text{red}}^{-1}(\text{Gal}_\infty(\mathcal{H}_{\text{red}})).$$

(4.6) $\text{Gal}_\infty(\mathcal{H}) = \{ j\sigma \in \text{Gau}(\Gamma(\mathcal{H})) \mid j\text{det}(\sigma) \in \text{Gal}_\infty(\mathcal{H}_{\text{det}}) \}$

which is defined by the differential equations,

$$\partial_\tau \sigma = \left( \begin{array}{c} 0 \\ \frac{\alpha \beta}{\tau(1-\tau)} \\ \frac{(\alpha+\beta+1)x-\gamma}{\tau(1-\tau)} \end{array} \right), \sigma$$
\[ \partial_x \det(\sigma) = \partial_e \det(\sigma) = \partial_a \left( \frac{\partial_a \det(\sigma)}{\det(\sigma)} \right) = \partial_b \left( \frac{\partial_b \det(\sigma)}{\det(\sigma)} \right) = \partial_c \left( \frac{\partial_c \det(\sigma)}{\det(\sigma)} \right) = 0. \]

where \( \sigma \) is an invertible \( 2 \times 2 \) matrix depending on \( x, \alpha, \beta, \gamma \) and the differential operators \( \partial_a, \partial_b, \partial_c \) are those given in Proposition 4.4.

**APPENDIX A. DIFFERENTIAL ALGEBRAIC GROUPS**

Our treatment of differential algebraic groups is the geometrical theory proposed in [Mal10a]. This formulation is slightly different from the better known algebraic formulation in [Kol85]. Here we recall and comment the most important results, including Malgrage’s version of Kiso-Cassidy theorem.

**A.1. Differential algebraic groups.** Let \( \pi_G : \mathcal{G} \to B \) a group bundle. As before, we assume \( \mathcal{G} \) to be affine over \( B \). The jet bundle \( J_k(\mathcal{G}/B) \to B \) of \( k \)-jets of sections of \( \pi_G \) is an algebraic group bundle with the group operation \( j_2^k (gj_2^k h) = j_2^k (gh) \). We consider \( O_{J_k(\mathcal{G}/B)} \) the ring of differential functions of order \( \leq k \) with rational coefficients in \( B \). We may interpret it as the ring of regular functions in \( J_k(\mathcal{G}/B) \) seen as an algebraic \( \mathbb{C}(B) \)-group. The group structure induces, by duality, a Hopf \( \mathbb{C}(B) \)-algebra structure on \( O_{J_k(\mathcal{G}/B)} \).

Remark A.1. Note that, by Cartier theorem (for instance, in [DG70]) \( \mathbb{C}(B) \)-algebraic groups are smooth (and therefore reduced), so that, Hopf ideals of \( O_{J_k(\mathcal{G}/B)} \) are radical.

Remark A.2. There is a natural bijective correspondence between Hopf ideals of \( O_{J_k(\mathcal{G}/B)} \) and rational group subbundles of \( J_k(\mathcal{G}/B) \to B \). Given a Hopf ideal \( \mathcal{E} \), the set of zeros of \( \mathcal{E} \cap C(J_k(\mathcal{G}/B)) \) is rational group subbundle. By abuse of notation we will refer to it as the set of zeros of \( \mathcal{E} \).

The group multiplication is compatible with the order truncation, therefore we may take the projective limit, so that the jet bundle \( J(\mathcal{G}/B) \) is a pro-algebraic group bundle and its ring of coordinates (on the generic point of \( B \)) \( O_{J(\mathcal{G}/B)} = \mathbb{C}(B) \otimes_{\mathbb{C}[B]} \mathbb{C}[J(\mathcal{G}/B)] \) a Hopf \( \mathbb{C}(B) \)-algebra.

Indeed, \( O_{J(\mathcal{G}/B)} \) is endowed with a differential ring structure, with the total derivative operators \( X(B)_{\text{tot}} \). The Hopf and the differential structure are compatible in the following sense:

\[ \mu^*(X_{\text{tot}} f) = (X_{\text{tot}} \otimes 1 + 1 \otimes X_{\text{tot}}) \mu^*(f), \quad e^*(X_{\text{tot}} f) = X(e^*(f)), \]

where \( \mu^* \) and \( e^* \) stand for the coproduct and coidentity operators. Hence, we may say that \( O_{J(\mathcal{G}/B)} \) is a Hopf-differential algebra.

**Definition A.3.**

1. A Hopf-differential ideal of \( O_{J(\mathcal{G}/B)} \) is a Hopf ideal \( \mathcal{E} \) of \( O_{J(\mathcal{G}/B)} \) such that \( X_{\text{tot}} \mathcal{E} \subset \mathcal{E} \) for every rational vector field \( X \) on \( B \).

2. A differential algebraic subgroup \( H \subset J(\mathcal{G}/B) \) is a Zariski closed subset consisting of the zero locus of some Hopf-differential ideal \( \mathcal{E} \) of \( O_{J(\mathcal{G}/B)} \).

As differential-Hopf ideals are radical (Remark A.1), we have that the natural correspondence between differential-Hopf ideals of \( O_{J(\mathcal{G}/B)} \) and differential algebraic subgroups of \( J(\mathcal{G}/B) \) is, in fact, bijective.

**Example A.4.** Let \( \mathcal{G} = \text{GL}_n(\mathbb{C}) \times B \). A differential algebraic subgroup \( H \subset J(\mathcal{G}/B) \) is a differential algebraic group of \( \mathcal{G}(U) \) defined over \( \mathbb{C}(B) \) in the sense of Kolchin (as in [Kol85]), where \( U \) a universal differential field extension of \( \mathbb{C}(B) \).

Given a Hopf-differential ideal \( \mathcal{E} \), its truncation \( \mathcal{E}_k = \mathcal{E} \cap O_{J_k(\mathcal{G}/B)} \) is Hopf-ideal of \( O_{J_k(\mathcal{G}/B)} \). Thus, a differential algebraic subgroup of \( J(\mathcal{G}/B) \) is given by a chain of Hopf ideals

\[ \mathcal{E}_0 \subset \mathcal{E}_1 \subset \ldots \subset \mathcal{E}_k \subset \ldots \subset \mathcal{E} \]
and thus, a system of rational group subbundles of the $J_k(\mathbb{S}/B)$,

$$H \to \ldots \to H_k \to \ldots \to H_1 \to H_0 \to B.$$  

The differential ring $\mathcal{O}_{J(\mathbb{S}/B)}$ is, by construction, the quotient of a ring of differential polynomials with coefficients in $\mathbb{C}(B)$. Thus, it has the Ritt property (see, for instance, [Kol73]): radical differential ideals are finitely generated as radical differential ideals. Thus, there is a smallest order $k$ such that $E$ coincides with $\{E_k\}$, the radical differential ideal spanned by $E_k$. We have that $H$ is completely determined by $H_k$ and we say that $H$ is a differential algebraic subgroup of $J(\mathbb{S}/B)$ of order $k$.

A section of $H$ is a section $g$ of $\pi_{\mathbb{S}}$: $\mathbb{S} \to B$ such that $j_x g \in H$ for any $x$ in the domain of definition of $g$. We can deal with rational, local analytic, convergent, or formal sections of $H$. We can also speak of sections of $H_w$ with coefficients in any differential field extension of $\mathbb{C}(B)$.

Example A.5. The points of $H$ in the sense of Kolchin (as in Example A.4) are sections of $H$ with coefficients in arbitrary differential field extensions of $\mathbb{C}(B)$. In that context, it is useful to fix a differentially closed field extension of $\mathbb{C}(B)$ so that $H$ is determined by its sections.

A.2. Differential Lie algebras. Let us consider $\pi_{\mathbb{S}}$: $\mathbb{S} \to B$ as before; let us define $\mathfrak{g} = e^*(\ker(d\pi_{\mathbb{S}}))$, therefore $\pi_{\mathbb{S}}: \mathfrak{g} \to B$ is the Lie algebra bundle associated to $\mathbb{S}$.

In an analogous way the jet bundles of finite order $J_k(\mathbb{g}/B) \to B$ are Lie algebra bundles and the limit $J(\mathbb{g}/B) \to B$ is a pro-algebraic linear bundle of Lie algebras; the Lie bracket is defined as $[j_x v_1, j_x v_2] = j_x [v_1, v_2]$ for jets of local analytic sections.

We consider its ring of coordinates on the generic point of $B$, $\mathcal{O}_{J(\mathbb{g}/B)} = \mathbb{C}(B) \otimes_{\mathbb{C}[B]} \mathbb{C}[J(\mathbb{g}/B)]$. It has a Lie coalgebra structure with the induced comultiplication,

$$\beta^* : \mathcal{O}_{J(\mathbb{g}/B)} \to \mathcal{O}_{J(\mathbb{g}/B)} \otimes_{\mathbb{C}(B)} \mathcal{O}_{J(\mathbb{g}/B)}; \quad b^*(f)(j_x v_1, j_x v_2) = f([j_x v_1, j_x v_2]).$$

Moreover, $\mathcal{O}_{J(\mathbb{g}/B)}$ is a differential ring with the differential structure induced by total derivative operators $\mathcal{X}(B)^{\text{tot}}$. Indeed, the linear bundle structure of $J(\mathbb{g}/B)$ is reflected in the ring $\mathcal{O}_{J(\mathbb{g}/B)}$: linear differential functions are identified with linear differential operators from the space of sections of $\mathfrak{g}$ on $\mathbb{C}(B)$. We have a sub-$\mathcal{X}(B)$-module $\text{Diff}_B(\mathfrak{g}) \subset \mathcal{O}_{J(\mathbb{g}/B)}$ that spans the ring of differential functions (as in [Mal10a] section 4).

Definition A.6. A differential Lie subalgebra $\mathfrak{h} \subset J(\mathbb{g}/B)$ is a Zariski closed subset consisting of the zeroes of a differential ideal $\mathcal{E}$ of $\mathcal{O}_{J(\mathbb{g}/B)}$ satisfying:

1. $\mathcal{E}$ is spanned by its linear part $\mathcal{E} \cap \text{Diff}_B(\mathfrak{g})$.
2. $\mathcal{E}$ is a Lie co-ideal.

Note that a differential Lie subalgebra is also a differential subgroup with respect to the additive structure of $\mathfrak{g}$. There is an smallest $k$ such that $\{E_k\} = \mathcal{E}$, the order of $\mathfrak{h}$; and $\mathfrak{h}$ is determined by its truncation $\mathfrak{h}_k$.

A differential algebraic group $H$ has an associated differential Lie algebra $\mathfrak{h}$ of the same order. For each $\ell$, the Lie algebra bundle $\mathfrak{h}_\ell \to B$ is (on the generic point of $B$) the Lie algebra of the group bundle $H_\ell \to B$. Equations of $\mathfrak{h}$ can be found by linearization of the equations of $H$ along the identity (see [Mal10a], section 4.5).

A.3. Group connections. Let us consider a regular connection $\mathcal{C}$ on $\pi_{\mathbb{S}}$: $\mathbb{S} \to B$, that is, a regular foliation in $\mathbb{S}$ transversal to the fibers of $\pi_{\mathbb{S}}$. For each $g \in \mathbb{S}$ the leaf of $\mathcal{C}$ that passes through $g$ is the graph of a local analytic section $\tilde{g}$ of $\pi_{\mathbb{S}}$. The connection $\mathcal{C}$ defines a regular map,

$$\gamma_{\mathcal{C}}: \mathbb{S} \to J(\mathbb{S}/B), \quad g \mapsto j_{\pi_{\mathbb{S}}(g)} \tilde{g};$$

that is a section of $J(\mathbb{S}/B) \to \mathbb{S}$ and identifies $\mathbb{S}$ with the set of jets of $\mathcal{C}$-horizontal sections $\Gamma(\mathcal{C})$. 

Definition A.7. We say that $\mathcal{C}$ is a group connection if $\gamma_\mathcal{C}$ is a group bundle morphism.

In general, a rational group connection is a regular group connection defined on some dense Zariski open subset of $B$. Given a rational group connection $\mathcal{C}$, the variety $\Gamma(\mathcal{C})$ of $\mathcal{C}$-horizontal leaves is an order 1 differential algebraic subgroup of $J(\mathcal{G}/B)$ isomorphic (as group bundle, on the generic point of $B$) to $\mathcal{G}$.

Remark A.8. Differential algebraic groups of the form $\Gamma(\mathcal{C})$, for a group connection $\mathcal{C}$, correspond to constant differential algebraic groups in the sense of Kolchin [Kol85]. The group connection is the differential equation of the conjugation of the differential algebraic group with an algebraic group over the constants.

Analogously, a regular linear connection $\mathcal{L}$ in $\mathfrak{g} \to B$ induces a section $\gamma_\mathcal{L}$ of $J(\mathfrak{g}/B) \to \mathfrak{g}$ which is linear in fibers. We say that $\mathcal{L}$ it is a Lie connection if $\gamma_\mathcal{L}$ is a Lie algebra morphism in fibers. A rational Lie connection is a regular Lie connection in some Zariski open subset of $B$. The variety of horizontal sections $\Gamma(\mathcal{L})$ of a rational Lie connection is a differential Lie subalgebra of $J(\mathfrak{g}/B)$ of order 1.

It is clear that a group connection $\mathcal{C}$ can be linearized along the identity, producing Lie connection $\mathcal{C}'$ with the same domain of regularity. In such case, $\Gamma(\mathcal{C}')$ is the Lie algebra of $\Gamma(\mathcal{C})$.

We may also define partial group and Lie connections. Let us fix $\mathcal{F}$ a singular foliation in $B$. Let us recall that a $\mathcal{F}$-connection in $\mathcal{G}$ (resp. $\mathfrak{g}$) is just an foliation $\mathcal{C}$ of the same rank of $\mathcal{F}$ and that projects onto $\mathcal{F}$. A local section is $\mathcal{C}$-horizontal if its derivative maps $\mathcal{F}$ to $\mathcal{C}$. The jets of local sections of $\mathcal{C}$ define a closed subset $\Gamma(\mathcal{C})$ in $J(\mathcal{G}/B)$ (resp. in $J(\mathfrak{g}/B)$).

$$\Gamma(\mathcal{C}) = \{ j_x \mathfrak{s} \mid x \in B, \mathfrak{s} \text{ local } \mathcal{C} - \text{horizontal section} \}.$$

A partial group $\mathcal{F}$-connection is a partial Ehresmann $\mathcal{F}$-connection $\mathcal{C}$ whose set of horizontal sections $\Gamma(\mathcal{C}) \subset J(\mathcal{G}/B)$ is a differential algebraic group. A partial Lie $\mathcal{F}$-connection is a $\mathcal{F}$-connection whose set of horizontal sections is a differential Lie subalgebra. As before, those objects are of order 1, and the linearization of a group $\mathcal{F}$-connection is a Lie $\mathcal{F}$-connection.

We say that a differential subgroup $H \subset J(\mathcal{G}/B)$ is Zariski dense in $\mathcal{G}$ if $H_0 = \mathcal{G}$. In the algebraic setting, the classification of Zariski dense subgroups in simple groups is due to Cassidy [Cas89]. We follow the exposition of Malgrange, that finds the key argument of the proof in the a result of Kiso [Kis79].

Theorem A.9 (Kiso-Cassidy, Th. 8.1 in [Mal10a]). Let $\mathfrak{g} \to B$ be a Lie algebra bundle with simple fibers. Let $\mathfrak{h} \subset J(\mathfrak{g}/B)$ be a differential subalgebra such that $\mathfrak{h}_0 = \mathfrak{g}$. Then there is a singular foliation $\mathcal{F}$ in $B$ and a partial Lie $\mathcal{F}$-connection $\mathcal{C}$ in $\mathfrak{g}$ such that $\mathfrak{h} = \Gamma(\mathcal{C})$.

Corollary A.10. Let $\mathcal{G} \to B$ be a group bundle with simple fibers. Let $H \subset J(\mathfrak{g}/B)$ be a differential algebraic subgroup such that $H_0 = \mathcal{G}$. Then there is a singular foliation $\mathcal{F}$ in $B$ and a partial group $\mathcal{F}$-connection $\mathcal{C}$ in $\mathcal{G}$ such that $H = \Gamma(\mathcal{C})$.

A.4. The adjoint connection. Let us consider now $\pi : P \to B$ a principal bundle with structural group $G$. Let $\mathcal{F}$ be a singular foliation on $B$ and $\mathcal{D}$ be a partial $G$-invariant $\mathcal{F}$-connection on $P$. Let $F$ be an affine $G$-space with an action $\alpha : G \to \text{Aut}(F)$. The associated bundle associated bundle $P[\alpha]$ is defined as the balanced construction $P \times_\alpha F$; it is a bundle $P[\alpha] \to B$ with fibers $F$. The $G$-invariant foliation $\mathcal{D} \times \{0\}$ in $P \times F$ projects onto a foliation on $P[\alpha]$ that we call $\alpha(\mathcal{D})$; it is the induced partial Ehresmann $\mathcal{F}$-connection on $P[\alpha]$.

Let $\text{Gau}(P) \to B$ be the group bundle of gauge automorphisms of $P$. Let us recall that $\text{Gau}(P)$ can be constructed as the associated bundle $P[\text{Adj}] = (P \times_{\text{Adj}} G)$ for the adjoint action of $G$ on itself. The induced $\mathcal{F}$-connection $\text{Adj}(\mathcal{D})$ turns out to be a group $\mathcal{F}$-connection in $\text{Gau}(P)$.

Theorem A.11 (Th. 7.6 in [Mal10a]). Assume that $G$ is semi-simple and connected, and let $\mathcal{F}$ a singular foliation in $B$. Then all partial group $\mathcal{F}$-connections in $\text{Gau}(P)$ are of the form $\text{Adj}(\mathcal{D})$ where $\mathcal{D}$ is a partial $G$-invariant $\mathcal{F}$-connection in $P$. 
Remark A.12. Note that, since the adjoint action of semi-simple $G$ in itself is faithful, the $G$-invariant partial connection $\mathcal{D}$ inducing $\text{Adj}(\mathcal{D})$ is unique.

Example A.13. Let us consider compatible linear equations in $P = \text{GL}_n(\mathbb{C}) \times \mathbb{C}^{n+m}$:

$$\frac{\partial U}{\partial x_i} = A_i(x, s)U.$$ 

Then $\text{Gau}(P) = \text{GL}_n(\mathbb{C}) \times \mathbb{C}^{n+m}$ and the induced group connection is

$$\frac{\partial \sigma}{\partial x_i} = [A_i(x, s), \sigma].$$

The horizontal sections $\sigma(x, s)$ are gauge symmetries of the equation.

Theorems A.9 and A.11 give us a complete description of Zariski dense differential algebraic subgroups of $J(\text{Gau}(P)/B)$ when $G$ is simple and connected. Such subgroups are of the form $\Gamma(\text{Adj}(\mathcal{D}))$ for a partial $G$-invariant connections $\mathcal{D}$ in $P$.

**Appendix B. Parametrized Picard-Vessiot Theory**

Here we discuss the relation between the differential Galois theory for connections with parameters, and the parameterized Picard-Vessiot theory presented in [CS06].

Let us consider a rational (in practice, we assume regular) partial $\text{GL}_n(\mathbb{C})$-invariant connection $\mathcal{D}$ on $P = \text{GL}_n(\mathbb{C}) \times B$ parameterized by $\rho: B \to S$, with $\mathbb{C}(S)$ relatively algebraically closed in $\mathbb{C}(B)$. We consider the following basis of $\mathfrak{X}(B)$: we take a transcendence basis $\{s_1, \ldots, s_m\}$ of $\mathbb{C}(S)$ and then extend it to a transcendence basis $\{s_1, \ldots, s_m, x_1, \ldots, x_m\}$; then we consider $\Pi = \left\{\frac{\partial}{\partial s_i}\right\}$, $\Lambda = \left\{\frac{\partial}{\partial x_i}\right\}$ and $\Delta = \Pi \cup \Lambda$. Then $\mathbb{C}(B)$ is a $\Delta$-field, and $\mathbb{C}(B)^\Lambda = \mathbb{C}(S)$. The differential equation for the $\mathcal{D}$-horizontal sections is a linear integrable system,

$$\left(B.1\right) \quad \frac{\partial U}{\partial x_i} = A_i U, \quad A_i \in \mathfrak{gl}_n(\mathbb{C}(B)),$$

satisfying compatibility conditions

$$\frac{\partial A_i}{\partial x_j} - \frac{\partial A_j}{\partial x_i} = [A_i, A_j].$$

**Definition B.1 ([CS06] Def. 9.4(1)).** A PPV ring over $\mathbb{C}(B)$ for the equation (B.1) is a $\Delta$-ring $R$ containing $\mathbb{C}(B)$ and satisfying:

- (a) $R$ is a $\Delta$-simple $\Delta$-ring (i.e. it does not contain non-trivial $\Delta$-ideals).
- (b) There exist a matrix $\Phi \in \text{GL}(R)$ such that $\frac{\partial \Phi}{\partial x_i} = A_i \Phi$.
- (c) $R$ is spanned, as $\Delta$-ring by the entries of $\Phi$ and the inverse of its determinant; $R = \mathbb{C}(B)\{\Phi, \Phi^{-1}\}_\Delta$.

Let us recall the construction of the differential variety $\Gamma(\mathcal{D}) \subset J(P/B)$. It is the variety of jets of horizontal sections, so that

$$\mathcal{O}_{\Gamma(\mathcal{D})} = \mathcal{C}(B)\{u_{ij}, \det(u_{ij})^{-1}\}_\Delta / \mathcal{E}$$

Where $\mathcal{E}$ is the radical differential ideal spanned by the connection $\mathcal{E} = \left\{\frac{\partial u_{ij}}{\partial x_k} - a_{ik}u_{kj}\right\}$. Therefore, by construction, $\mathcal{O}_{\Gamma(\mathcal{D})}$ satisfies conditions (a) and (c) of the definition, but it is not in general $\Delta$-simple. However, the following is clear.

**Proposition B.2.** For any maximal $\Delta$-ideal $\mathfrak{m} \subset \mathcal{O}_{\Gamma(\mathcal{D})}$ the quotient $R_{\mathfrak{m}} = \mathcal{O}_{\Gamma(\mathcal{D})}/\mathfrak{m}$ is a PPV ring over $\mathbb{C}(B)$ for equation (B.1).

**Definition B.3 ([CS06] Def. 9.4(2)).** A PPV field over $\mathbb{C}(B)$ for the equation (B.1) is a $\Delta$-field $R$ containing $\mathbb{C}(B)$ and satisfying:
(a) There exist a matrix $\Phi \in \text{GL}(L)$ such that $\frac{\partial \Phi}{\partial x_i} = A_i \Phi$.

(b) $L$ is spanned, as $\Delta$-ring by the entries of $\Phi$, $L = \mathbb{C}(B)(\Phi, \Phi^{-1})_{\Delta}$.

(c) $L^A = \mathbb{C}(B)^A$

A big problem is that PPV rings does not always produce PPV fields, and we do not have in general an uniqueness theorem, unless the field of $\Lambda$-constants is constrainedly closed (which it is not the case in our scope).

However, let us assume that $\rho \circ \pi: P \to S$ admit a section $\tau$. Since $P$ is a direct product $\tau = (\phi, \bar{\tau})$, so that $\bar{\tau}$ is a section of $\rho$. Then, we can consider the section $\tau$ as an initial value condition for (B.1), so that $\tau$ prolongs to a section $j\tau: S \to \Gamma(\mathcal{D})$ that maps each $s \in S$ to $j_{\pi_0(\tau(s))} \Phi$ where $\Phi$ is the solution of the initial value problem:

$$\frac{\partial \Phi}{\partial x_i} = A_i \Phi, \quad \Phi(\bar{\tau}(s)) = \phi(s).$$

Now, we consider $T_{\tau} = V(j\tau(S), \mathcal{D}(\infty))$ the smallest subvariety variety of $\Gamma(\mathcal{D})$ that contains the image of $j\tau$ and it is differential (tangent to $\mathcal{D}(\infty)$). This $T_{\tau}$ (our candidate for torsor) is by construction the zero locus of a maximal differential ideal $m_{\tau}$.

**Proposition B.4.** The $\Delta$-field extension $\mathbb{C}(B) \subset \mathbb{C}(T_{\tau})$ is a PPV field over $\mathbb{C}(B)$ for equation (B.1).

**Proof.** A first observation is that the PPV ring $\mathcal{O}_{T_{\tau}}$ is not only $\Delta$-simple but also $\Lambda$-simple.

Let us note that for each $k$, the truncation $T_{\tau, k}$ is the smallest subvariety tangent to $\mathcal{D}(k)$ that contains the image of $j_{\tau}$. If $m$ is a non-trivial maximal $\Lambda$-ideal of $\mathcal{O}_{T_{\tau}}$ then its zero locus is a subsvariety $T' \subset T_{\tau}$ strictly contained in $T_{\tau}$ that dominates $B$ by projection. We may take an algebraic section $\tau'$ from $S$ to $T'$ such that $\pi_0 \circ \tau' = \pi \circ \tau$, where $\pi_0$ is the projection from $J(P/B)$ to $B$. Then, we have an algebraic map $g: S \to \tau_m G$ such that $j\tau \cdot g = \tau'$. Then, $T' \cdot g^{-1}$ contains the image of $j\tau$ and it is strictly contained in $T_{\tau}$.

Therefore, for any $k$ we have that $T'_{\tau, k}$ is a subvariety of $T_{\tau, k}$ containing the image of $j_{\tau, k}$. Since the ideal of $T'_{\tau, k}$ is a $\Lambda$-ideal, we have that $(T' \cdot g^{-1})_k$ is tangent to $\mathcal{D}(k)$. Therefore, by the minimality of $T_{\tau, k}$ we have that $T'_{\tau, k}(T' \cdot g^{-1}) = T_{\tau, k}$, for all $k$, so that $(T' \cdot g^{-1}) = T_{\tau}$, and then $T' = T_{\tau}$.

Let $F \in \mathbb{C}(T_{\tau})$ be a $\Lambda$-constant. It defines a non-zero $\Lambda$-ideal of $\mathcal{O}_{T_{\tau}}$,

$$\{b \in \mathcal{O}_{T_{\tau}} : bF \in \mathcal{O}_{T_{\tau}}\}.$$  

This ideal must be (1) and then we have $F \in \mathcal{O}_{T_{\tau}}$. We have that $j\tau^*: \mathcal{O}_{T_{\tau}} \to \mathbb{C}(S)$ is a retract of the embedding of $\mathbb{C}(S)$ into $\mathcal{O}_{T_{\tau}}$, and it is a $\Pi$-ring morphism. Then, $F - j\tau^*(F)$ is a $\Lambda$-constant, and then it is also a $\Pi$-constant, so that it is a $\Delta$-constant, and therefore a complex number. Moreover $F$ and $j\tau^*(F)$ coincide along the image of $j(\tau)$ so we have that $F = j\tau^*(F)$, a rational function in $S$. 

**Remark B.5.** Note that $\tau$ admit always an algebraic section, therefore, in our scope, there is always a Picard-Vessiot extension after an algebraic extension of $\mathbb{C}(S)$. The existence of such extensions was proved in a much more general situation in [Wib12].

In $\Gamma(\mathcal{D})$ we have the following situation. The group bundle $\text{Gau}(\Gamma(\mathcal{D}))$ of gauge symmetries of $\mathcal{D}$, and the group $J(\text{GL}_n(\mathbb{C})/S)$ of right translations depending on parameters acts on the right side. These actions commute.

$$\text{Gau}(\Gamma(\mathcal{D})) \times_B \Gamma(\mathcal{D}) \times_S J(\text{GL}_n(\mathbb{C})/S) \to \Gamma(\mathcal{D}).$$

In order to understand the relation between the Galois group bundle $\text{Gal}_{\infty}(\mathcal{D})$ and the parameterized Picard-Vessiot group of [CS06] let us first examine what happens in case without parameters, where $S$ reduces to a point. In such case $\tau$ is just a point $p \in P$. By Gómez-Mont theorem (Theorem 25) we may consider a complete integral $f: P \to V$ of $\mathcal{D}$ with $V$ a model for $\mathbb{C}(P)^{\mathcal{D}}$ and we have that $T = f^{-1}f(p)$.
Let us consider Stb\((T)\) the algebraic subgroup of \(G\) that stabilizes \(T\) by right translations. It acts in \(\mathbb{C}(T)\) by \(\mathbb{C}(B)\)-automorphisms on the left side, and it is the differential Galois group \(\text{Aut}_\Lambda(\mathbb{C}(T)/\mathbb{C}(B))\) of classical Picard-Vessiot theory (without parameters).

The action of the Galois bundle \(\text{Gal}(\mathcal{D})\) respects the values of rational first integrals of \(\mathcal{D}\). Therefore we have \(\text{Gal}(\mathcal{D}) \times_B T \times \text{Stb}(T) \to T\) a restricted action. The fibers of \(T\) are principal homogeneous spaces, on the right side for \(\text{Stb}(T)\) and on the left side for the fibers of \(\text{Gal}(\mathcal{D})\). If we fix the point \(x = \pi(p)\) we have a group isomorphism:

\[
\psi: \text{Gal}(\mathcal{D})|_x \xrightarrow{\sim} \text{Stb}(T), \quad g_x \mapsto \psi(g_x) \text{ with } g_x p = p \psi(g_x)
\]

The case with parameters \(S\) and a section \(\tau\) is not so different. As \(T_\tau\) is the zero locus of a \(\Delta\)-ideal, we have that the stabilized of \(T_\tau\) is a differential algebraic subgroup of \(J(\text{GL}_n(\mathbb{C}/S))\).

Also, by iterated application of Gómez-Mont theorem we may construct a complete integral \(f_\infty: \Gamma(\mathcal{D}) \to V_\infty\) of \(\mathcal{D}^{(\infty)}\) where \(V_\infty\) is a model of \(\mathbb{C}(\Gamma(\mathcal{D}))^{\mathcal{D}^{(\infty)}}\). We have a commutative diagram,

\[
\begin{array}{ccc}
\Gamma(\mathcal{D}) & \xrightarrow{f_\infty} & V_\infty \\
\downarrow{j_\tau} & & \downarrow{S} \\
& \text{Stb}(T_\tau) &
\end{array}
\]

and \(T_\tau = f_\infty^{-1}(f_\infty(j_\tau(S)))\). Be definition, the action of \(\text{Gal}_\infty(\mathcal{D})\) preserves \(f_\infty\) and therefore it stabilizes \(T_\tau\). We have again left and right actions,

\[
\text{Gal}_\infty(\mathcal{D}) \times_B T_\tau \times_S \text{Stb}(T_\tau) \to T_\tau
\]

such that any fiber of \(T_\tau\) is a principal homogeneous space for the corresponding fibers of \(\text{Gal}_\infty(\mathcal{D})\) and \(\text{Stb}(T_\tau)\).

The relation between the differential algebraic group \(\text{Stb}(T_\tau) \to S\) and the automorphisms of \(\mathbb{C}(T_\tau)\) is as follows. A rational section of \(\text{Stb}(T_\tau)\) is a rational section \(g\) of \(\text{Stb}_0(T_\tau)\) (the 0-th order truncations) whose jet prolongation \(jg\) is a section of \(\text{Stb}(T_\tau)\). Rational sections of \(\text{Stb}(T_\tau)\) act in \(\mathbb{C}(T_\tau)\) by \(\mathbb{C}(B)\)-automorphisms. Indeed, if we consider an universal \(\Delta\)-field \(\mathcal{U}\) containing \(\mathbb{C}(T_\tau)\) then sections of \(\text{Stb}(T)\) with coefficients in some \(\Pi\)-field \(\mathcal{K} \subset \mathcal{U}^\Lambda\) yield \(\mathbb{C}(B)\)-isomorphisms of \(\mathbb{C}(T_\tau)\) into \(\mathbb{C}(B) \cdot \mathcal{K}\).

As before, we can restrict \(\text{Gal}_\infty(\mathcal{D})\), not to a point of \(B\) but along the section \(\bar{\tau}\) of \(\rho\), so that \(\bar{\tau}^*(\text{Gal}_\infty(\mathcal{D})) \to S\) is a differential algebraic group over \(S\). We have an isomomorphism of differential algebraic groups,

\[
\psi: \bar{\tau}^*(\text{Gal}_\infty(\mathcal{D})) \xrightarrow{\sim} \text{Stb}(T_\tau), \quad \sigma_{\bar{\tau}(s)} \mapsto g_s \text{ with } \sigma_{\bar{\tau}(s)} j_{\bar{\tau}(s)} = j_{\bar{\tau}(s)} g_s.
\]

Remark B.6. Note that \(\bar{\tau}^*\) kills the derivatives in \(\Lambda\), therefore if we are interested in presenting the equations of the computed Galois groups in the setting of [CS06], as differential algebraic groups over \(S\), we only need to take \(x\) constant and omit the equations of \(\Gamma(\text{Adj}(\mathcal{D}))\) (which are transversal to \(j_{\bar{\tau}}\)) involving the derivative with respect to \(x\).
