ON THE EULER-ALIGNMENT SYSTEM WITH WEAKLY SINGULAR COMMUNICATION WEIGHTS

CHANGHUI TAN

Abstract. We study the pressureless Euler equations with nonlocal alignment interactions, which arises as a macroscopic representation of complex biological systems modeling animal flocks. For such Euler-Alignment system with bounded interactions, a critical threshold phenomenon is proved in [18], where global regularity depends on initial data. With strongly singular interactions, global regularity is obtained in [9], for all initial data. We consider the remaining case when the interaction is weakly singular. We show a critical threshold, similar as the system with bounded interaction. However, different global behaviors may happen for critical initial data, which reveals the unique structure of the weakly singular alignment operator.

1. Introduction

We are interested in the Euler-Alignment system, which takes the form
\[ \partial_t \rho + \nabla \cdot (\rho u) = 0, \]
\[ \partial_t u + u \cdot \nabla u = \int \psi(|x-y|)(u(y) - u(x))\rho(y)dy. \]

The system arises as a macroscopic representation of models characterizing collective behaviors, in particular, alignment and flocking.

Here, \( \rho \) represents the density of the group, and \( u \) is the associated velocity. The term appears at the right hand side of (2) is the alignment force. It was first proposed by Cucker and Smale in [8] in the microscopic model
\[ \dot{x}_i = v_i, \quad m\dot{v}_i = \frac{1}{N} \sum_{j=1}^{N} \psi(|x_i - x_j|)(v_j - v_i). \]
\( \psi : \mathbb{R}^+ \rightarrow \mathbb{R} \) is called the communication weight, measuring the strength of the alignment interaction. A natural assumption on \( \psi \) is that it is a decreasing function, as the strength of interaction is weaker when the distance is larger.

The alignment force in the Cucker-Smale system (3) intends to align the velocity of all particles as time becomes large. The corresponding flocking phenomenon has been proved in [11], under appropriate assumptions on the communication weight.

The Euler-Alignment system (1)-(2) can be derived from the Cucker-Smale system (3), through a kinetic description, as a hydrodynamic limit. See [12] for a formal derivation, [3, 19] for discussions on the kinetic system, and [10, 14] for rigorous passages to the limit.

1.1. Bounded interaction. The Euler-Alignment system (1)-(2) with bounded Lipschitz was first studied in [18], where a critical threshold phenomenon is proved: subcritical initial data lead to global smooth solutions, while supercritical initial data lead to finite time singularity formations.

In a successive work [3], a sharp critical threshold condition is obtained in 1D, with the help of an important quantity
\[ G(x, t) = \partial_x u(x, t) + \int \psi(x-y)\rho(y, t)dy. \]

One can easily obtain the dynamics of \( G \), see [3], as follows
\[ \partial_t G + \partial_x (Gu) = 0. \]
This together with the dynamics of \( \rho \)
\[ \partial_t \rho + \partial_x (\rho u) = 0, \]
can serve as an alternative representation of (1)-(2). The velocity field \( u \) can be recovered by (1).

The following theorem shows the sharp critical threshold condition.
Theorem 1.1 ([3]). Consider the 1D Euler-Alignment system (5)-(6) with smooth initial data \((\rho_0, G_0)\).

- If \(\inf_x G_0(x) \geq 0\), then there exists a globally regular solution.
- If \(\inf_x G_0(x) < 0\), then the solution admits a finite time blowup.

For 2D Euler-Alignment system, the threshold conditions are obtained in [18], and also in [13] with a further improvement. However, neither result is sharp.

1.2. Strongly singular interaction. One family of influence functions has the form

\[
\psi(r) = r - s.
\]  

When \(s > 0\), \(\psi\) is unbounded at \(r = 0\). This corresponds to the case when the alignment interaction becomes very strong as the distance becomes smaller.

In the case when \(s > n\), where \(n\) is the dimension, \(\psi(|x|)\) is not integrable at \(x = 0\). It has been studied recently that the so called strongly singular interaction has a regularization effect, which prevents the solution from finite time singularity formations. In 1D, global regularity is obtained in [9] for \(s \in (1, 2)\), and in [17] for \(s \in [2, 3)\) through a different approach.

Theorem 1.2 ([9, 17]). Consider the 1D Euler-Alignment system (5)-(6) with smooth periodic initial data \((\rho_0, G_0)\). Suppose \(\rho_0 > 0\). Then, there exists a globally regular solution.

Note that since \(\psi\) is not integrable, the quantity \(G\) in (4) is not well-defined. For \(\psi\) defined in (7), one can use an alternative quantity \(G = \partial_x u - (-\Delta)^{(s-1)/2}\rho\). For general choice of \(\psi\) with the same singularity at \(x = 0\), a similar global regularity result has been obtained in [15].

The dynamics in 2D is much more complicated and far less understood. Global regularity has been obtained recently in [16] only for a small class of initial data.

1.3. Weakly singular interaction. We are interested in the Euler-Alignment system (1)-(2) with weakly singular interactions. This corresponds to the case when \(\psi(|x|)\) is integrable, namely \(\psi(r)\) behaves like \(r^{-s}\) near origin with \(s \in (0, n)\).

In this case, the quantity \(G\) is well-defined as long as the solution \((\rho, u)\) is smooth, since

\[
\|G\|_{L^\infty} \leq \|u\|_{W^{1,\infty}} + \|\psi\|_{L^1} \|\rho\|_{L^\infty}.
\]

So in 1D, one would expect a similar critical threshold phenomenon as Theorem 1.1. However, the result is not always true.

Let us consider a special case when \(G_0(x) \equiv 0\). Since \(G\) satisfies (5), it is easy to see that \(G(x, t) = 0\) in all time. The dynamics of \(\rho\) can be written as

\[
\partial_t \rho + \partial_x (\rho u) = 0, \quad u(x, t) = -\int K'(x - y)\rho(y, t)dy, \quad K''(x) = \psi(x).
\]

It is the aggregation equation with a convex potential \(K\) (as \(\psi \geq 0\)).
The global wellposedness of the aggregation equation has been well-studied. A sharp Osgood condition has been derived in \[1, 2, 4\], which distinguishes global regularity and finite time density concentration: the solution is globally regular if and only if
\[
\int_0^1 \frac{1}{K'(r)} dr = \infty.
\]
(9)

For weakly singular interaction \(\psi \sim r^{-s}\) with \(s \in (0, 1)\) near origin, or more precisely,
\[
\lambda r^{-s} \leq \psi(r) \leq \Lambda r^{-s}, \quad \Lambda \geq \lambda > 0, \quad s \in (0, 1),
\]
(10)
uniformly in \(r \in (0, 1]\), the Osgood condition (9) is violated, and hence the solution generates concentrations in finite time. The behavior is different from the bounded interaction case \((s = 0)\), in which (9) holds.

In this paper, we study the global behavior of the Euler-Alignment system with weakly singular interactions.

The following two theorems show a similar behavior to the system with bounded interactions (Theorem 1.1), for both supercritical and subcritical regions of initial data.

**Theorem 1.3** (Supercritical threshold condition). Consider the 1D Euler-Alignment system (5) - (6) with smooth initial data \((\rho_0, G_0)\) and weakly singular interaction \(\psi\) satisfying (10).

If \(\inf_x G_0(x) < 0\), then the solution admits a finite time blowup.

**Theorem 1.4** (Subcritical threshold condition). Consider the 1D Euler-Alignment system (5) - (6) with smooth initial data \((\rho_0, G_0)\) and weakly singular interaction \(\psi\) satisfying (10).

If \(\inf_x G_0(x) > 0\), then there exists a globally regular solution.

The theorems imply that different behaviors between systems with bounded and weakly singular interactions can only happen for critical initial data

\[
\inf_x G_0(x) = 0.
\]

The example above \((G_0(x) \equiv 0)\) falls into this category. The following theorem describes a large set of critical initial data, with which the solution blows up in finite time.

**Theorem 1.5** (Blowup for critical initial data). Consider the 1D Euler-Alignment system (5) - (6) with smooth initial data \((\rho_0, G_0)\) and weakly singular interaction \(\psi\) satisfying (10).

If \(G_0(x) \geq 0\), and there exists an interval \(I = [a, b]\) with \(a < b\) such that for any \(x \in I\), \(G_0(x) = 0\) and \(\rho_0(x) > 0\), then the solution admits a finite time blowup.

The theorem says, if \(G_0\) reaches zero in any non-vacuum interval, then the solution will blow up in finite time. Very importantly, such initial data will lead to a global smooth solution if the communication weight is regular, due to Theorem 1.1. The different long time behaviors distinguish the two types of interactions, and reveal the unique property of the weakly singular interactions.
The rest of the paper is organized as follows. In section 2, we develop a local well-posedness theory of the 1D Euler-Alignment system, as well as a Beale-Kato-Majda criteria that ensures the regularity. Sections 3 and 4 are devoted to prove Theorem 1.3 and 1.4 respectively. A nonlinear maximum principle is introduced to take care of the weak singularity on the communication weight. The critical case is investigated in section 5. We introduce a new proof for the blowup of the aggregation equation. It utilizes local information and can be extended to the Euler-Alignment system, proving Theorem 1.5. Finally, in Section 6 we make comments on the extension of our theory to higher dimensions.

2. LOCAL WELLPOSEDNESS AND BLOWUP CRITERION

We start our discussion with a local wellposedness theory of our main system in 1D. Recall the 1D Euler-Alignment system in \((\rho, G)\) representation
\[
\begin{align*}
\partial_t \rho + \partial_x (\rho u) &= 0, \\
\partial_t G + \partial_x (G u) &= 0, \\
\partial_x u &= G - \psi * \rho,
\end{align*}
\]
where \(*\) stands for convolution in \(x\) variable.

**Theorem 2.1** (Local wellposedness). Consider the 1D Euler-Alignment system \((11)-(13)\) with smooth initial data with finite mass \((\rho_0, G_0) \in (H^s \cap L^1_+)(\Omega) \times H^s(\Omega)\). Suppose the communication weight is integrable:
\[
\psi \in L^1(\Omega).
\]
Then, there exists a time \(T > 0\) such that the solution
\[
(\rho, G) \in C([0, T]; (H^s \cap L^1_+)(\Omega)) \times C([0, T]; H^s(\Omega)).
\]
Moreover, the solution stays smooth up to time \(T\) as long as
\[
\int_0^T \left( \|\rho(\cdot, t)\|_{L^\infty} + \|G(\cdot, t)\|_{L^\infty} \right) dt < +\infty.
\]

**Proof.** We first state an \(H^s\)-estimate on \(\rho\)
\[
\frac{d}{dt} \|\rho(\cdot, t)\|_{H^s}^2 \lesssim \left[ \|\rho\|_{L^\infty} + \|\partial_x u\|_{L^\infty} \right] \left( \|\rho\|_{H^s}^2 + \|\partial_x u\|_{H^s}^2 \right).
\]
The proof can be found, for instance, in [3, Theorem Appendix A.2].

As \(G\) satisfies the same continuity equation as \(\rho\), we have
\[
\frac{d}{dt} \|G(\cdot, t)\|_{H^s}^2 \lesssim \left[ \|G\|_{L^\infty} + \|\partial_x u\|_{L^\infty} \right] \left( \|G\|_{H^s}^2 + \|\partial_x u\|_{H^s}^2 \right).
\]

Putting these two estimate together, we obtain
\[
\frac{d}{dt} \left( \|\rho(\cdot, t)\|_{H^s}^2 + \|G(\cdot, t)\|_{H^s}^2 \right) \lesssim \left[ \|\rho\|_{L^\infty} + \|G\|_{L^\infty} + \|\partial_x u\|_{L^\infty} \right] \left( \|\rho\|_{H^s}^2 + \|G\|_{H^s}^2 + \|\partial_x u\|_{H^s}^2 \right).
\]
From the relation (13), we can estimate $\partial_x u$ by $\rho$ and $G$ as follows. For a fixed time $t$,

$$\|\partial_x u\|_{L^\infty} \leq \|\psi \ast \rho\|_{L^\infty} + \|G\|_{L^\infty} \leq \|\psi\|_{L^1} \|\rho\|_{L^\infty} + \|G\|_{L^\infty},$$

$$\|\partial_x u\|_{H^s} \leq \|\psi \ast \rho\|_{H^s} + \|G\|_{H^s} \leq \|\psi\|_{L^1} \|\rho\|_{H^s} + \|G\|_{H^s}.$$

Since $\|\psi\|_{L^1}$ is bounded, we now arrive at the estimate

$$\frac{d}{dt}(\|\rho(\cdot, t)\|_{H^s}^2 + \|G(\cdot, t)\|_{H^s}^2) \leq \|\rho(\cdot, t)\|_{L^\infty} + \|G(\cdot, t)\|_{L^\infty} (\|\rho(\cdot, t)\|_{H^s}^2 + \|G(\cdot, t)\|_{H^s}^2).$$

Standard Gronwall inequality implies

$$\|\rho(\cdot, t)\|_{H^s}^2 + \|G(\cdot, t)\|_{H^s}^2 \leq (\|\rho_0\|_{H^s}^2 + \|G_0\|_{H^s}^2) \exp \left[ \int_0^T \|\rho(\cdot, s)\|_{L^\infty} + \|G(\cdot, s)\|_{L^\infty} ds \right].$$

Therefore, if condition (15) is satisfied, $\rho(\cdot, t), G(\cdot, t) \in H^s(\mathbb{R})$ for all $t \in [0, T]$. This ends the proof of the theorem. \qed

We shall make several remarks regarding Theorem 2.1.

**Remark 2.1.** A local wellposedness proof for 1D Euler-Alignment system has been done in [3] Theorem Appendix A.1, with an additional assumption on $\psi$

$$\int_0^t x\psi'(x)dx < +\infty.$$  

Here, we relax the assumption by making use of the $(\rho, G)$ formulation of the system.

If assumption (14) is violated, namely $\psi$ is not integrable at the origin, then the behavior of the equation changes dramatically due to the strongly singular interaction. We refer to [9, 15] for discussions on local and global regularities under such setup.

**Remark 2.2.** Condition (15) is called the Beale-Kato-Majda (BKM) type criteria. It provides a sufficient and necessary condition under which the solution stays smooth. Condition (15) is equivalent to

$$\int_0^T \|\partial_x u(\cdot, t)\|_{L^\infty} dt < +\infty,$$

which is a standard sufficient condition to ensure the wellposedness of the characteristic paths for pressureless Euler dynamics. The equivalency is due to the following estimates

$$\int_0^T \|\partial_x u(\cdot, t)\|_{L^\infty} dt \leq \int_0^T (\|\rho(\cdot, t)\|_{L^\infty} + \|\psi\|_{L^1} \|G(\cdot, t)\|_{L^\infty}) dt,$$

$$\|\rho(\cdot, t)\|_{L^\infty} + \|G(\cdot, t)\|_{L^\infty} \leq (\|\rho_0\|_{L^\infty} + \|G_0\|_{L^\infty}) \exp \left[ \int_0^T \|\partial_x u(\cdot, s)\|_{L^\infty} ds \right].$$

**Remark 2.3.** When $\Omega = \mathbb{R}$, assumption (14) can be further generalized to

$$\psi \in L^1(\mathbb{R}) + \text{const.}$$

This allows us to include more types of communication weight, for instance $\psi \equiv 1$. We include a short proof for the sake of completeness.
Proof of Remark 2.3. Let \( \psi = \psi_0 + c \), where \( \psi_0 \in L^1(\mathbb{R}) \) and \( c \) is a constant. Define \( G = \partial_x u + \psi_0 \star \rho \). Then, the \((\rho, G)\) representation of the 1D Euler-Alignment system reads
\[
\partial_t \rho + \partial_x (\rho u) = 0, \quad \partial_t G + \partial_x (Gu) = -cm\partial_x u, \quad \partial_x u = G - \psi_0 \star \rho,
\]
where \( m = \int_{\Omega} \rho_0(x) dx \) is the total mass which is preserved in time.

Due to the extra term in the dynamics of \( G \), the \( H^s \) estimate on \( G \) becomes
\[
\frac{d}{dt} \| G(\cdot,t) \|^2_{H^s} \lesssim \| G \|_{L^\infty} + \| \partial_x u \|_{L^\infty} \left( \| G \|_{H^s}^2 + \| \partial_x u \|_{H^s}^2 \right) + cm \| G \|_{H^s} \| \partial_x u \|_{H^s} \lesssim [1 + \| G \|_{L^\infty} + \| \partial_x u \|_{L^\infty}^2] \left( \| G \|_{H^s}^2 + \| \partial_x u \|_{H^s}^2 \right).
\]

The rest of the proof stays the same as Theorem 2.1. \( \Box \)

A natural question would be, whether the BKM criteria (15) can be further reduced to
\[
\int_0^T \| G(\cdot,t) \|_{L^\infty} dt < +\infty. \tag{17}
\]

In another word, whether boundedness of \( G \) implies boundedness of \( \rho \). If so, global regularity of the system becomes equivalent to the boundedness of \( G \).

The following proposition shows that condition (17) indeed serves as a BKM criterion for the 1D Euler-Alignment system, when the communication weight is bounded.

**Proposition 2.1** (An enhanced BKM criterion for system with bounded interactions). Consider the initial value problem of the 1D Euler-Alignment system (11)-(13) with smooth initial data \((\rho_0, G_0) \in (H^s \cap L^1_+)(\Omega) \times H^s(\Omega)\). Suppose the communication weight is bounded and integrable:
\[
\psi \in (L^1 \cap L^\infty)(\Omega) + \text{const.}
\]
Suppose criteria (17) is satisfied for time \( T \). Then, the solution is smooth up to time \( T \), namely
\[
(\rho, G) \in C([0, T]; (H^s \cap L^1_+)(\Omega)) \times C([0, T]; H^s(\Omega)).
\]

**Proof.** It suffices to prove that (17) implies (15).

Consider the characteristic path \( X(t) := X(t; x_0) \) starting at \( x_0 \in \Omega \)
\[
\frac{d}{dt} X(t; x_0) = u(X(t; x_0), t), \quad X(0; x_0) = x_0.
\]
As \( \rho \) satisfies the continuity equation (11), we get
\[
\frac{d}{dt} \rho(X(t), t) = -\partial_x u(X(t), t)\rho(X(t), t).
\]
Then,
\[
\rho(X(t), t) = \rho_0(x) \exp \left[ -\int_0^t \partial_x u(X(s), s) ds \right] \leq \rho_0(x) \exp \left[ \int_0^t \| \partial_x u(\cdot, s) \|_{L^\infty} ds \right].
\]
Since \( \psi \) is bounded, we can estimate
\[
\| \partial_x u(\cdot, t) \|_{L^\infty} \leq \| G(\cdot, t) \|_{L^\infty} + m \| \psi \|_{L^\infty}. \tag{18}
\]
Therefore, we get
\[ \| \rho(\cdot, t) \|_{L^\infty} \leq \| \rho_0 \|_{L^\infty} \exp \left[ m \| \psi \|_{L^\infty} t + \int_0^t \| G(\cdot, t) \|_{L^\infty} ds \right]. \]

Hence, the boundedness of \( G \) does imply the boundedness of \( \rho \). \( \Box \)

Using Proposition 2.1, one can easily prove Theorem 1.1, by showing criterion (17) is satisfied if and only if \( \inf_x G_0(x) \geq 0 \). We refer readers to [3] for details.

When the communication weight is weakly singular, Proposition 2.1 might be false. In particular, the estimate (18) is no longer available. One alternative bound could be
\[ \| \partial_x u(\cdot, t) \|_{L^\infty} \leq \| G(\cdot, t) \|_{L^\infty} + \| \rho(\cdot, t) \|_{L^\infty} \| \psi \|_{L^1}. \]

It implies an implicit bound
\[ \| \rho(\cdot, t) \|_{L^\infty} \leq \| \rho_0 \|_{L^\infty} \exp \left[ m \| \psi \|_{L^1} \int_0^t \| \rho(\cdot, s) \|_{L^\infty} ds + \int_0^t \| G(\cdot, t) \|_{L^\infty} ds \right], \]

which is not enough to obtain boundedness of \( \rho \).

In fact, a counter example such that Proposition 2.1 fails for weakly singular interaction has been mentioned in the introduction, where \( G_0(x) \equiv 0 \). The corresponding aggregation system (8) is known to have a finite time loss of regularity as long as \( \psi \) is unbounded at the origin. Therefore, the global regularity theory of Euler-Alignment system with bounded interaction can not be directly extended to the case when the interaction is weakly singular.

3. Supercritical threshold condition

3.1. Finite time blowup on \( G \). In this section, we prove Theorem 1.3: solution forms a singularity in finite time, for supercritical initial data
\[ \inf_{x \in \Omega} G_0(x) < 0. \]

Under such configuration, there exists an \( x_0 \in \Omega \) such that \( G_0(x_0) < 0 \). Denote \( X(t) \) be the characteristic path starting at \( x_0 \)
\[ \frac{d}{dt} X(t) = u(X(t), t), \quad X(0) = x_0. \]

As long as the solution stays smooth, alongside \( X(t) \), we have
\[ \frac{d}{dt} G(X(t), t) = -\partial_x u(X(t), t) G(X(t), t). \]

This implies
\[ G(X(t), t) = G_0(x_0) \exp \left[ \int_0^t \partial_x u(X(s), s) ds \right] < 0. \]

Moreover, \( \psi \ast \rho(\cdot, t) \geq 0 \) for any \( t \geq 0 \). From (13), we get
\[ \frac{d}{dt} G(X(t), t) = -G^2(X(t), t) + G(X(t), t) (\psi \ast \rho(\cdot, t))(X(t)) \leq -G^2(X(t), t). \]
Applying a classical comparison principle, we obtain

\[ G(X(t), t) \leq \frac{1}{t + \frac{1}{G_0(x_0)}} \xrightarrow{t \to -T} -\infty. \]

Therefore, there exists a finite time \( T \leq -\frac{1}{G_0(x_0)} \), such that

\[ \lim_{t \to T^-} G(X(t), t) = -\infty. \] (19)

The BKM criterion (15) fails at time \( T \), which leads to a loss of regularity.

Now, we discuss the behavior of the solution \((\rho, u)\) at the blowup time \( T \).

**Lemma 3.1.** Let \( T \) be the time that the first blowup of \( G \) occurs, and the corresponding location is \( x = X(T; x_0) \). Suppose the solution \((\rho, u)\) stays smooth for \( t \in [0, T) \). Then, the solution develops a shock at time \( T \) and location \( x \), namely

\[ \lim_{t \to T^-} \partial_x u(X(t; x_0), t) = -\infty. \]

Moreover, if \( \rho_0(x_0) > 0 \), then the density concentrates at the shock location (called singular shock)

\[ \lim_{t \to T} \rho(X(t; x_0), t) = +\infty. \]

**Proof.** From (13), we know \( \partial_x u \leq G \). This together with (19) implies shock formation

\[ \partial_x u(X(t; x_0), t) \leq G(X(t; x_0), t) \xrightarrow{t \to T} -\infty. \]

Define \( F = G/\rho \). Then, \( F \) satisfies the local transport equation

\[ \partial_t F + u \partial_x F = 0. \]

Since \( \rho_0(x_0) > 0 \), \( F_0 \) is bounded and smooth in a neighborhood of \( x_0 \). Then, \( F \) is well-defined alongside the characteristic path \( X(t; x_0) \), and

\[ F(X(t; x_0), t) = F_0(x_0). \]

Therefore, we obtain a concentration of density

\[ \rho(X(t; x_0), t) = \frac{\rho_0(x_0)}{G_0(x_0)} G(X(t; x_0), t) \xrightarrow{t \to T} +\infty. \]

\[ \square \]

Lemma 3.1 does not rule out the possibility that blowup happens before \( G \) becomes singular. Indeed, the BKM criterion (15) could fail if \( \rho \) becomes unbounded.

We now construct an example when \( \rho \) blows up before \( G \). This would imply that the criterion (17) itself does not guarantee regularity of the system. So Proposition 2.1 is no longer true for the system with weakly singular interactions.
3.2. An example: \( \rho \) blows up before \( G \). Take \( \Omega = \mathbb{R} \). Let \( \rho_0 \) be a smooth function supported in \((0, 1)\).

Let \( \eta \) be a smooth function such that \( \eta \geq 0 \), \( \max_x \eta(x) = 1 \), and \( \text{supp} \eta = (0, 1) \). Consider the following \( G_0 \)

\[
G_0(x) = -\epsilon \eta(x - L),
\]

where \( L > 0 \) is a large number, and \( \epsilon > 0 \) is a small positive number to be chosen. As \( \inf G_0(x) = -\epsilon < 0 \), \( G_0 \) is a supercritical initial condition.

Note that \( \text{supp}(G_0) = (L, L + 1) \). If \( L \) is large enough, \( \text{supp}(\rho_0) \cap \text{supp}(G_0) = \emptyset \). Starting from any \( x_0 \in \text{supp}(\rho_0) \), we have \( G_0(x_0) = 0 \) and consequently \( G(X(t; x_0), t) = 0 \). So, \( \partial_x u = -\psi \ast \rho \) in the support of \( \rho \), since \( \partial_x u \) is locally depended on \( G \). Therefore, the dynamics of \( \rho \) does not depend on \( G \), and it is the same as the aggregation equation \( \square \). Since \( \psi \) is singular, we know the density \( \rho \) concentrates at a finite time \( T_* \), which is independent of \( L \) and \( \epsilon \).

The goal is to show \( G \) remains regular at time \( T_* \). It suffices to prove that \( G \) is bounded from below at \( T_* \). To this end, we shall obtain a lower bound estimate on \( G \). Fix \( x_0 \in \text{supp}(G_0) \). Then, along its characteristic path, we have

\[
\frac{d}{dt} G(X(t; x_0), t) = -G(X(t; x_0), t) \partial_x u(X(t; x_0), t) = -G^2 + G \psi \ast \rho. \tag{21}
\]

As \( G(X(t; x_0), t) < 0 \), we need an upper bound on \( \psi \ast \rho \).

If the supports of \( \rho(\cdot, t) \) and \( G(\cdot, t) \) are well-separated, namely

\[
\text{dist}(\text{supp}(\rho(\cdot, t)), \text{supp}(G(\cdot, t))) \geq 1, \tag{22}
\]

for \( t \in [0, T_*] \), then we have the estimate

\[
\psi \ast \rho(X(t; x_0), t) = \int_{\text{supp}(\rho)} \psi(X(t; x_0) - y, t) \rho(y, t) dy \leq \psi(1) \int_{\text{supp}(\rho)} \rho(y, t) dy = \psi(1) m.
\]

Let us denote the constant \( C = \psi(1) m \). It is uniform in \( x_0 \in \text{supp}(G_0) \) and \( t \in [0, T_*] \). Apply the estimate to (21), we get

\[
\frac{d}{dt} G(X(t; x_0), t) \geq -G^2 - CG.
\]

An explicit calculation yields

\[
G(X(t; x_0), t) \geq -\frac{C}{G_0(x_0) - \epsilon} e^{-Ct} - 1.
\]

So, if \( G_0(x_0) \geq -C \), then

\[
G(X(t; x_0), t) \geq -C, \quad \forall \ t \in \left[ 0, \frac{1}{C} \ln \left( \frac{C - G_0(x_0)}{-2G_0(x_0)} \right) \right].
\]

Note that

\[
\lim_{z \to 0^+} \left[ \frac{1}{C} \ln \left( \frac{C - z}{-2z} \right) \right] = +\infty.
\]
It means that if we pick \( \epsilon \) small enough, \( G(\cdot, t) \) can be bounded below by \(-C\) for a sufficiently long time. In particular, we can choose \( \epsilon \) small enough, e.g.
\[
\epsilon = \frac{C}{2e^{CT_\ast} - 1},
\]
so that \( G \) is bounded until \( t = T_\ast \).

It remains to show that condition (22) holds at \( t \in [0, T_\ast] \).

One important feature of the Euler-Alignment system (1)-(2) is that the velocity is uniformly bounded in time
\[
\|u(\cdot, t)\|_{L^\infty} \leq \|u_0\|_{L^\infty}.
\]
Indeed, a maximum principle can be easily derived from (2) (see for instance [18]). Moreover, under additional assumptions, not only boundedness but also contraction on \( u \) can be proved, which reveals the so-called flocking phenomenon.

Take \( x_1 \in \text{supp}(\rho_0) \) and \( x_2 \in \text{supp}(G_0) \). Then,
\[
\frac{d}{dt} (X(t; x_2) - X(t; x_1)) = u(X(t; x_2), t) - u(X(t; x_1), t) \geq -2\|u(\cdot, t)\|_{L^\infty} \geq -2\|u_0\|_{L^\infty}.
\]
Hence,
\[
X(t; x_2) - X(t; x_1) \geq (x_2 - x_1) - 2t\|u_0\|_{L^\infty} \geq (L - 1) - 2t\|u_0\|_{L^\infty}.
\]
If we take \( L \) big enough (e.g. \( L = 2 + 2T_\ast\|u_0\|_{L^\infty} \)), then the distance will remain big at time \( T_\ast \). Therefore, (22) holds for \( t \in [0, T_\ast] \).

3.3. The BKM criterion. The example above states that \( \rho \) could blow up before \( G \). On the other hand, \( G \) could blow up before \( \rho \) as well. Examples can be constructed similarly, by letting \( \epsilon \) in (20) large.

Therefore, both terms in the BKM criterion (15) are necessary to ensure regularity. This is very different from the system with bounded interactions.

4. Subcritical threshold condition

In this section, we turn to study the Euler-Alignment system with weakly singular interactions, for subcritical initial data
\[
\inf_{x \in \Omega} G_0(x) > 0. 
\]
Since \( G \) satisfies the continuity equation (12), it is easy to show that positivity preserves in time, namely
\[
G(x, t) > 0, \quad \forall \ x \in \Omega, \ t \geq 0.
\]
Hence, the blowup (19) can not happen. However, unlike the case with bounded interactions, the boundedness of \( G \) (criterion (17)) is not enough to ensure global regularity, as argued in Section 3.3. In order to prove Theorem 1.4 we need to obtain bounds on both \( G \) and \( \rho \).
4.1. A global estimate on $\rho$. We start with an estimate on $\rho$. Along the characteristic path, we have

$$\frac{d}{dt} \rho(X(t), t) = -\rho(X(t), t) \partial_x u(X(t), t) = -\rho + \rho \psi * \rho.$$ 

The first term on the right hand side is a good term that helps bring down the value of $\rho$ alongside the characteristic path, while the second term is a bad term.

**Step 1: An estimate on the good term.** Let $q = \rho/G = 1/F$. Then, $q$ satisfies the transport equation

$$\partial_t q + u \partial_x q = 0.$$ 

Since $G_0$ satisfies (23), $q_0$ is bounded and smooth. Clearly, we have

$$q(X(t; x), t) = q_0(x).$$ 

Therefore, we obtain a lower bound estimate on $G$

$$G(X(t; x), t) = \frac{\rho(X(t; x), t)}{q(X(t; x), t)} = \frac{\rho(X(t; x), t)}{q_0(x)} \geq \frac{\rho(X(t; x), t)}{\|q_0\|_{L^\infty}}.$$ 

It yields an estimate on the good term

$$-\rho G \leq -C_1 \rho^2,$$ 

where the constant $C_1 = 1/\|q_0\|_{L^\infty}$ is bounded and depend only on the initial data.

**Step 2: An estimate on the bad term.** To estimate the bad term, and to compare with the good term, we need a local bound on $\psi * \rho$.

A nonlinear maximum principle is introduced in [7] which offers a local bound, at the extrema of $\rho$, when $\psi$ is strongly singular. Here, we state a lemma which serves as a nonlinear maximum principle for weakly singular kernel.

**Lemma 4.1** (Nonlinear maximum principle). Let $\psi$ be a weakly singular communication weight satisfying condition (10). Consider a function $f \in L^1_\Lambda(R)$ and a point $x_*$ such that $f(x_*) = \max f(x)$. Then, there exists a constant $C > 0$, depending on $\Lambda$, $s$ and $\|f\|_{L^1}$, such that

$$\psi * f(x_*) \leq C f(x_*)^s.$$ 

**Proof.** First of all, since $\psi * f \leq (\Lambda|x|^{-s}) * f$, it suffices to prove (25) for $\psi(x) = |x|^{-s}$. For any $a > 0$, we compute

$$(|x|^{-s} * f)(x_*) = \int_{|y| \leq a} f(x_* - y)|y|^{-s}dy + \int_{|y| > a} f(x_* - y)|y|^{-s}dy$$

$$= f(x_*) \int_{|y| \leq a} |y|^{-s}dy - \int_{|y| \leq a} (f(x_* - f(x_* - y))|y|^{-s}dy + \int_{|y| > a} f(x_* - y)|y|^{-s}dy$$

$$\leq \frac{2a^{1-s}}{1-s} f(x_*) - a^{-s} \int_{|y| \leq a} (f(x_* - f(x_* - y))dy + a^{-s} \int_{|y| > a} f(x_* - y)dy$$

$$= \frac{2a^{1-s}}{1-s} f(x_*) - 2a^{1-s} f(x_*) + a^{-s} \|f\|_{L^1} = \frac{2s}{1-s} a^{1-s} f(x_*) + a^{-s} \|f\|_{L^1}.$$
Take \( a = \|f\|_{L^1}/(2f(x_*)) \), we obtain
\[
((|x|^{-s}) \ast f)(x_*) \leq \left( \frac{2 - s}{1 - s} \|f\|_{L^1}^{1-s} \right) f(x_*)^s.
\]

\[\square\]

We now apply Lemma 4.1 with \( f = \rho(\cdot, t) \). Fix any time \( t \), and let \( x_* \) be the location where maximum of \( \rho(\cdot, t) \) is attained. Then,
\[
\rho(x_*, t) \psi \ast \rho(x_*, t) \leq C_2 \rho(x_*, t)^{1+s}, \tag{26}
\]
where the constant \( C_2 = C_2(\Lambda, s, m) > 0 \).

**Step 3: a uniform upper bound on \( \rho \).** Combining the two estimates \[24\] and \[26\], we obtain that if \( x_* \) is a point such that \( \rho(x_*, t) = \max_x \rho(x, t) \), then
\[
\partial_t \rho(x_*, t) \leq C_1 \rho(x_*, t)^2 - C_2 \rho(x_*, t)^{1+s}.
\]
So, when \( \rho \) is large enough such that \( \rho \geq (C_2/C_1)^{1/(1-s)} \), then \( \partial_t \rho(x_*, t) \leq 0 \). Therefore, we obtain an apriori bound on the density
\[
\|\rho(\cdot, t)\|_{L^\infty} \leq \max \{\|\rho_0\|_{L^\infty}, (C_2/C_1)^{1/(1-s)}\} =: C_\rho, \quad \forall \ t \geq 0.
\]
Note that the bound \( C_\rho = C_\rho(\Lambda, s, m, \|\rho_0\|_{L^\infty}, \|q_0\|_{L^\infty}) \) is independent of time. Therefore, \( \|\rho(\cdot, t)\|_{L^\infty} \) is uniformly bounded.

4.2. **An estimate on \( G \).** We are left to bound \( G \), which is not hard to obtain given the apriori estimate on \( \rho \).

Along the characteristic path, \( G \) satisfies \[21\]. Recall
\[
\frac{d}{dt} G(X(t), t) = -G^2 + G \psi \ast \rho.
\]
The uniform bound on \( \rho \) implies a bound on \( \psi \ast \rho \)
\[
\|\psi \ast \rho\|_{L^\infty} \leq \|\psi\|_{L^1} \|\rho\|_{L^\infty} \leq \|\psi\|_{L^1} C_\rho, \quad \forall \ t \geq 0.
\]
Therefore, we obtain
\[
\frac{d}{dt} G(X(t), t) \leq -G(G - \|\psi\|_{L^1} C_\rho).
\]
So, \( G \) can not grow along the characteristic path if \( G \geq \|\psi\|_{L^1} C_\rho \). It yields a uniform bound on \( G \)
\[
\|G(\cdot, t)\|_{L^\infty} \leq \{\|G_0\|_{L^\infty}, \|\psi\|_{L^1} C_\rho\}.
\]
5. The critical case

This section is devoted to discuss the critical case, when the initial condition satisfies
\[
\min_{x \in \mathbb{R}} G_0(x) = 0. \tag{27}
\]

Theorems 1.3 and 1.4 show that, the behavior of the Euler-Alignment system with weakly singular interactions is the same as the system with bounded interactions, in both subcritical and supercritical regimes. Therefore, different behaviors can only happen in the critical scenario.

One special critical initial condition is \(G_0(x) \equiv 0\). The system reduces to the aggregation equation (8). As we have argued in the introduction, the weakly singular interaction will drive the solution towards a finite time blowup. Therefore, Theorem 1.1 no longer holds.

A natural question arises: what happens for general critical initial data?

Recall the dynamics of the density \(\rho\) along the characteristic path
\[
dt[\rho(X(t), t)] = -\rho G + \rho \psi \ast \rho.
\]
If \(G_0(x_0) = 0\), then from (21) we have \(G(X(t), t) = 0\). Therefore, the good term \(-\rho G\) turns off near \(X(t)\), and the local behavior of dynamics becomes the same as the aggregation equation.

To capture such behavior, we shall first provide an alternative proof to the blowup of the aggregation equation. Unlike [1], the proof traces local information along the characteristic paths. The idea is partly inspired from [6].

5.1. A “local” proof for blowup of the aggregation equation. Let us consider the aggregation equation in the form
\[
\partial_t \rho + \partial_x (\rho u) = 0, \quad \partial_x u = -\psi \ast \rho.
\]
Without loss of generality, we assume that \(\rho_0\) is strictly positive in some interval \(I = [a, b]\), namely
\[
\rho_0(x) \geq c > 0, \quad \forall x \in [a, b]. \tag{28}
\]
Let \(r(t) = X(t; b) - X(t; a)\). Then,

\[
\frac{d}{dt} r(t) = u(X(t; b), t) - u(X(t; a), t) = \int_{X(t; a)}^{X(t; b)} \partial_x u(y, t) dy
\]
\[
= -\int_{X(t; a)}^{X(t; b)} (\psi \ast \rho)(y, t) dy = -\int_{X(t; a)}^{X(t; b)} \int_{-\infty}^{\infty} \psi(y - z) \rho(z, t) dy dz
\]
\[
\leq -\int_{X(t; a)}^{X(t; b)} \int_{X(t; a)}^{X(t; b)} \psi(y - z) \rho(z, t) dxdy.
\]
where the right hand side touches zero at standard comparison principle yields

\[ \frac{d}{dt} r(t) \leq -\lambda (2r(t))^{-s} r(t) \int_{X(t,a)}^{X(t,b)} \rho(z,t)dz. \]  

(29)

The following lemma shows a local conservation of mass along characteristic paths.

**Lemma 5.1 (Conservation of mass).** Let \( \rho \) be a strong solution of the continuity equation

\[ \partial_t \rho + \partial_x (\rho u) = 0. \]

Let \( X(t;x_1), X(t,x_2) \) be two characteristic paths starting at \( x_1 \) and \( x_2 \), respectively. Then,

\[ \int_{X(t;x_1)}^{X(t;x_2)} \rho(x,t)dx = \int_{x_1}^{x_2} \rho_0(x)dx, \quad \forall \ t \geq 0. \]  

(30)

Namely, the mass in the interval \([X(t;x_1), X(t;x_2)]\) is conserved in time.

**Proof.** Compute

\[
\frac{d}{dt} \int_{X(t;x_1)}^{X(t;x_2)} \rho(x,t)dx \\
= \rho(X(t;x_2),t) \frac{d}{dt} X(t;x_2) - \rho(X(t;x_1),t) \frac{d}{dt} X(t;x_1) + \int_{X(t;x_1)}^{X(t;x_2)} \partial_t \rho(x,t)dx \\
= \rho(X(t;x_2),t)u(X(t;x_2),t) - \rho(X(t;x_1),t)u(X(t;x_1),t) + \int_{X(t;x_1)}^{X(t;x_2)} \partial_t \rho(x,t)dx \\
= \int_{X(t;x_1)}^{X(t;x_2)} \partial_x (\rho(x,t)u(x,t)) dx + \int_{X(t;x_1)}^{X(t;x_2)} \partial_t \rho(x,t)dx = 0.
\]

This directly implies the conservation of mass \((30)\). \( \square \)

Applying Lemma 5.1 to (29) with \( x_1 = a \) and \( x_2 = b \), and using the lower bound assumption \((28)\), we obtain

\[
\frac{d}{dt} r(t) \leq -2^{-s} \lambda (r(t))^{1-s} \int_a^b \rho_0(z)dz \leq -2^{-s} c(b-a)\lambda (r(t))^{1-s}.
\]

For \( s \in (0,1) \), it is easy to show that \( r(t) \) reaches zero in finite time. Indeed, a standard comparison principle yields

\[
r(t) \leq \left[ (b-a)^s - 2^{-s} c(b-a)\lambda st \right]^{1/s},
\]

where the right hand side touches zero at

\[ T_\ast = \frac{2^s}{c(b-a)^{1-s}\lambda s} < \infty. \]

Then, \( r(t) \) should reach zero no later than \( T_\ast \).
The quantity $r(t) = 0$ means that two characteristic paths run into each other. It indicates a shock formation with $\partial_x u(x, t) \to -\infty$. Therefore, the solution loses regularity in finite time.

5.2. **Finite time blowup for a class of critical initial data.** Now, let us consider the Euler-Alignment system \((11)-(13)\) with critical initial data \((27)\).

Suppose there exists an interval $I = [a, b]$ such that $\rho_0$ is strictly positive, and $G_0$ is zero, namely

$$\forall \, x \in [a, b], \quad \rho_0(x) \geq c > 0, \quad G_0(x) = 0.$$  \hspace{1cm} (31)

Then, from (21) we obtain

$$G(x, t) = 0, \quad \forall \, t \geq 0, \quad x \in [X(t; a), X(t; b)].$$

Therefore, the dynamics of $\rho$ between the two characteristic paths $X(t; a)$ and $X(t; b)$ should be the same as the dynamics of the corresponding aggregation equation, as long as the solution stays smooth. The blowup estimates for the aggregation equation in Section 5.1 can be directly applied to the Euler-Alignment system. Therefore, the same type of blowup as the aggregation equation happens in finite time. This ends the proof of Theorem 1.5.

**Remark 5.1.** The condition (31) contains a large family of critical initial data, under which the global behaviors of the Euler-Alignment system is different between the bounded and weakly singular interactions. The condition is sharp in the following sense.

Consider the following critical initial data $(\rho_0, G_0)$:

$$\exists \, q_0 \in L^\infty, \quad \text{such that} \quad \rho_0(x) = q_0(x)G_0(x).$$  \hspace{1cm} (32)

Then, the arguments in section 4 can be easily extended, allowing $G_0(x) = 0$. Hence, the solution exists globally in time.

Note that condition (32) implies that $G_0(x) = 0$ only occurs at $\rho_0(x) = 0$, which is almost the opposite of condition (31). Therefore, condition (31) is a sharp condition so that the global behaviors of systems with bounded and weakly singular interactions are different from each other.

Rare exceptions could happen. For instance, $G_0(x) = 0$ only at a single point $x_0$, with $\rho_0(x_0) > 0$. It satisfies neither (31) nor (32). In this case, a more subtle “local” proof is required for the corresponding aggregation system in order to obtain a finite time blowup. This will be left for further investigations.

6. **Extensions to higher dimensions**

The global behaviors of the Euler-Alignment system \((1)-(2)\) is much less understood in higher dimensions. With bounded interactions, the system was first studied in [18] in two dimensions. Threshold conditions on initial data were obtained, but the result was not sharp.
The $G$ quantity can be defined as $G = \nabla \cdot u + \psi * \rho$. However, it does not satisfy the continuity equation any more. The dynamics of $G$ reads

$$
\partial_t G + \nabla \cdot (Gu) = \text{tr}(\nabla u^\otimes 2) - (\nabla \cdot u)^2.
$$

The right hand side is called the spectral gap, which is generally non-zero in two or higher dimensions.

The system in $(\rho, G)$ formulation in 2D has been studied in [13], where improved threshold conditions are obtained. However, the result is still far from being sharp, due to the lack of control in the spectral gap.

For the Euler-Alignment system with weakly singular interactions, our arguments on local wellposedness (Section 2) as well as both supercritical and subcritical threshold conditions (Sections 3 and 4) can be extended to higher dimensions, using similar techniques to handle the spectral gap. However, we are not able to distinguish the behaviors between the systems with bounded and weakly singular interactions (Section 5) until we get a sharp threshold condition.
