Abstract
In the field of constituent parsing, probabilistic grammar formalisms have been studied to model the syntactic structure of natural language. More recently, approaches utilizing neural models gained lots of traction in this field, as they achieved accurate results at high speed. We aim for a symbiosis between probabilistic linear context-free rewriting systems (PLCFRS) as a probabilistic grammar formalism and neural models to get the best of both worlds: the interpretability of grammars, and the speed and accuracy of neural models. A combination of these two could be achieved by applying supertagging to PLCFRS. This approach requires lexical grammar formalisms. Here, we present a procedure which turns any PLCFRS $G$ into an equivalent lexical PLCFRS $G'$. Moreover, we show how the derivations in $G'$ can be transformed to obtain their corresponding original derivations in $G$. Our construction for $G'$ preserves the probability assignment and does not increase parsing complexity compared to $G$.

1 Introduction
Constituency parsing is a syntactical analysis in NLP that aims to enhance sentences with, usually tree-shaped, phrase structures (for an example cf. the left of Fig. 1). Formalisms such as context-free grammars (CFG) are used in this setting because they are conceptually simple, interpretable, and parsing is tractable (cubic in sentence length).

Discontinuous constituents span non-contiguous sets of positions in a sentence. The resulting phrase structures do not take the shape of a tree anymore, as they contain crossing branches (cf. the left of Fig. 1), and cannot be modeled by CFG. As a countermeasure, many corpora (e.g., the Penn Treebank (PTB)) denote these phrase structures as trees nevertheless and introduce designated notations for discontinuity, which is then often ignored in parsing. However, discontinuity occurs in about 20% of the sentences in the PTB, and parsing discontinuous constituents can improve accuracy (Evang and Kallmeyer, 2011). For this, so-called “mildly context-sensitive” grammar formalisms have been investigated, e.g., tree-adjoining grammars (TAG; Joshi et al., 1975) and linear context-free rewriting systems (LCFRS; Vijay-Shanker et al., 1987). Their increased expressiveness comes at the cost of a higher parsing complexity: given a sentence of length $n$, parsing is in $O(n^6)$ for TAG and $O(n^{3 \cdot \text{fanout}(G)})$ for an LCFRS $G$. The fanout is grammar-specific and reflects the degree of discontinuity in the rules of $G$. The expressiveness of TAG equals that of LCFRS with fanout 2. An LCFRS derivation of a discontinuous phrase is shown in the right of Fig. 1.

Supertagging has been used for more efficient parsing with lexical TAG (Bangalore and Joshi, 1999). A TAG is lexical if each rule contains one word. A supertagger selects for each position of the input sentence a subset of the rules of the TAG; these are the so-called supertags. Parsing is then performed with the much smaller grammar of supertags. Recently, the performance of supertagging has been improved by using neural classifiers for the selection of supertags (Vaswani et al., 2016). The goal of our research is to use supertagging for parsing with LCFRS, because they are more expressive than TAG.

In this paper, we lay the theoretical foundations for a supertagging-based LCFRS parser. As LCFRS obtained from corpora such as the PTB are usually not lexical, we employ a lexicalization procedure. It can be seen as an instance of the technique for lexicalization of multiple context-free tree grammars (Engelfriet et al., 2018). However, our approach is more concise and does not increase the fanout of the grammar (thus preserving parsing complexity).
complexity). Moreover, the approach is extended to account for probabilistic parsing. Furthermore, we introduce a procedure which recovers from each derivation of a lexicalized LCFRS all corresponding derivations of the original grammar.

This short paper is to be seen as a report on our approaches to lexicalization and recovery of derivations. An implementation of the supertagger and experimental evaluation are currently work in progress.

2 Preliminaries

The set of non-negative (resp. positive) integers is denoted by $\mathbb{N}$ (resp. $\mathbb{N}_+$). Let $A$ be a set; the set of (finite) strings over $A$ is denoted by $A^*$. An alphabet is a finite and non-empty set.

Let $S$ be some set whose elements we call sorts. An $S$-sorted set is a tuple $(A, \text{sort})$ where $A$ is a set and $\text{sort} : A \rightarrow S$. Usually, we identify $(A, \text{sort})$ with $A$, and denote $\text{sort}$ by $\text{sort}_A$ and $\text{sort}_A^{-1}(s)$ by $A_s$ for each $s \in S$. The usual notation for sets $(\epsilon, \subseteq, \cup, \ldots)$ is used with sorted sets in the intuitive manner. Now let $A$ be an $(S^* \times S)$-sorted set. The set of trees over $A$ is the $S$-sorted set $T^A = \{a(t_1, \ldots, t_k) \mid k \in \mathbb{N}, s_1, \ldots, s_k \in S, a \in A_{(s_1 \ldots s_k)}, t_1 \in T^A_{s_1}, \ldots, t_k \in T^A_{s_k} \}$ for each $s \in S$. A ranked set $A$ is an $(S^* \times S)$-sorted set where $S = \{s\}$; the notation $\text{rk}_A(a) = k$ abbreviates $\text{sort}_A(a) = (s^k, s)$, and $A_s$ abbreviates $A_{(s^k, s)}$. If we use a usual set $B$ in place of a ranked set, we will silently assume $\text{rk}_B(b) = 0$ for each $b \in B$. Let $X$ be a set. We let $A(X) = \{a(x_1, \ldots, x_k) \mid k \in \mathbb{N}, a \in A_{s_k}, x_1, \ldots, x_k \in X\}$.

LCFRS. Linear context-free rewriting systems extend the rule-based string rewriting mechanism of CFG to string tuples; we describe the generation process by compositions. Let $k \in \mathbb{N}$ and $s_1, \ldots, s_k, s \in \mathbb{N}_+$; a $\Sigma$-composition is a tuple $(u_1, \ldots, u_k)$ where each $u_i$, $i = 1, \ldots, k$, is a non-empty set and $\Sigma = \{\Sigma_i \mid i \in [k]\}$. Each of these variables must occur exactly once in $u_1 \cdots u_k$ and they are ordered such that $x_i^1$ occurs before $x_i^{i+1}$ and $x_j^j$ occurs before $x_j^{j+1}$ for each $i \in [k - 1]$ and $j \in [k]$. We denote the set of $\Sigma$-compositions by $C^\Sigma_{(s_1 \ldots s_k)}$; we drop the superscript in the case $\Sigma = \emptyset$ (then $C_{(s_1 \ldots s_k)}$ is finite); we drop the subscript if we admit any configuration of $k, s_1, \ldots, s_k$ and $s$. We associate with each composition $(u_1, \ldots, u_k) \in C^\Sigma_{(s_1 \ldots s_k)}$ a function $C_{(s_1 \ldots s_k)} : \mathbb{N}_+ \rightarrow (A_{s_1} \cdots A_{s_k})$. The function is denoted by $[(u_1, \ldots, u_k)]$. Intuitively, it replaces each variable of the form $x_i^j$ in $u_1, \ldots, u_k$ by the $j$-th component of the $i$-th argument.

An LCFRS is a tuple $G = (N, \Sigma, S, R)$ where $N$ is a finite $\mathbb{N}_+$-sorted set (non-terminals), $\Sigma$ is an alphabet (terminals), $S \subseteq N_1$ (initial non-terminal), and $R$ is a finite $(N^* \times N^*)$-sorted set (rules). Each rule is of the form $A \rightarrow c(B_1, \ldots, B_k)$, where $k \in \mathbb{N}$, $A, B_1, \ldots, B_k \in N$, and $c \in C^\Sigma_{(\text{sort}_A(B_1) \cdots \text{sort}_A(B_k))}$. The sort of the rule is $(B_1 \cdots B_k, A)$; we call $A$ the left-hand side (lhs), $B_1, \ldots, B_k$ the right-hand side (rhs) and $c$ the rule’s composition. We drop the parentheses around the rhs if $k = 0$. We call rules of the form $A \rightarrow c$ where $A \neq S$ terminating, $A \rightarrow c(B)$ monic, and $A \rightarrow c(B_1, \ldots, B_k)$ where $k \geq 2$ branching, and denote the set of these rules in $R$ by $R^{(T)}$, $R^{(M)}$, and $R^{(B)}$, respectively. A rule is called lexical, if its composition contains at least one terminal. The lcfrs $G$ is called lexical, if each rule is lexical. The set of (complete) derivations in $G$ is $D^G = T^R_{S}$. Let $w \in \Sigma^*$ and $d = r(d_1, \ldots, d_k) \in T^R$.

Figure 1: Left: a discontinuous phrase structure tree of the sentence A hearing is scheduled on the issue today. Right: an LCFRS derivation of the discontinuous noun phrase A hearing on the issue.
with \( r = A \rightarrow c(B_1, \ldots, B_k) \). The yield of \( d \) is 
\[ \text{yd}(d) = [c](\text{yd}(d_1), \ldots, \text{yd}(d_k)). \]

**PLCFRS.** A probabilistic LCFRS is a tuple \((G, \mu)\) where \( G = (N, \Sigma, S, R) \) is an LCFRS and \( \mu : R \rightarrow [0, 1] \) maps each rule to a probability. The weight of a derivation \( d = r(d_1, \ldots, d_k) \in T^k \) is 
\[ \text{wt}(d) = \mu(r) \cdot \text{wt}(d_1) \cdots \text{wt}(d_k). \]

**Top-down Tree Transducers.** A top-down tree transducer (TT) is a tuple \( A = (Q, \Sigma, \Delta, q_0, \delta) \) where
- \( Q \) is a finite set (states), \( \Sigma \) and \( \Delta \) are ranked alphabets (input and output alphabet), and \( q_0 \in Q \) (initial state), and \( \delta \) is a finite set (transitions).
Each transition is of the form \( q(\sigma(x_1, \ldots, x_k)) \rightarrow t \), where \( \sigma \in \Sigma_k \) and \( t \in T^k. \)

We call a transition **linear** (resp. **non-deleting**) if each variable in \( x_1, \ldots, x_k \) occurs at most once (resp. at least once) in \( t \). We call \( A \) deterministic if, for each \( q \in Q \) an \( \sigma \in \Sigma \), \( q \) is at most one transition of the form \( q(\sigma(x_1, \ldots, x_k)) \rightarrow t \) in \( \delta \). We call it **linear** (resp. **non-deleting**) if each transition is linear (resp. non-deleting).

In a TT with \( \epsilon \)-rules (\( \varepsilon \)TT), the set \( \delta \) also contains transitions of the form \( q(x_1) \rightarrow t \) where \( t \in T^k. \)

The transduction of \( A \) is expressed in terms of the binary derivation relation \( \Rightarrow_A \) over \( T^k \). We write \( s \Rightarrow_A t \) if there is a subtree \( q(\sigma(s_1, \ldots, s_k)) \) in \( s \) and a transition \( q(\sigma(x_1, \ldots, x_k)) \rightarrow t' \) such that \( t \) is obtained by replacing \( q(\sigma(s_1, \ldots, s_k)) \) in \( s \) by \( t' \) and replacing \( x_i \) by \( s_i \) for each \( i \in [k] \).

The transduction of \( A \) is the relation \( \left[ A \right] = \left\{ (s, t) \in T^k \times T^k \mid q(s) \Rightarrow_A^* t \right\} \). If \( A \) is deterministic, we consider \( \left[ A \right] \) a function.

TTs are a special case of TTs with regular lookahead (TT\(^R\)) that were used by Engelfriet et al. (2018). For an excellent overview on tree transducers, we refer to Maletti (2010).

**Equivalence of (P)LCFRS.** Two LCFRS \( G \) and \( G' \) are called \( \text{ldTT}^R \)-**equivalent** if there are two linear and deterministic \( \text{TT}^R \), \( T \) and \( T' \), such that
- \( \left[ T \right](d) \in D^G \) and \( \text{yd}([T](d)) = \text{yd}(d) \)
- \( \left[ T' \right](d') \in D^{G'} \) and \( \text{yd}([T'](d')) = \text{yd}(d') \)

Two PLCFRS \((G, \mu)\) and \((G', \mu')\) are called \( \text{ldTT}^R \)-**equivalent** if \( G \) and \( G' \) are \( \text{ldTT}^R \)-equivalent and
- \( \text{wt}([T](d)) \geq \text{wt}(d) \) for each \( d \in D^G \), and
- \( \text{wt}([T'](d')) \geq \text{wt}(d') \) for each \( d' \in D^{G'} \).

\([T]\), as well as \([T']\), may map multiple derivations to one single derivation. The relation between the weights assures that this mapped derivation assumes the greatest of the original derivations’ weights.

**3 Lexicalizing LCFRS**

For the remainder, we assume (without loss of generality; cf. Seki et al., 1991) a PLCFRS \((G, \mu)\) where \( G = (N, \Sigma, S, R) \) is **terminal- and initial-separated**, i.e. each rule is either of the form \( A \rightarrow (\sigma) \) with \( \sigma \in \Sigma \) or \( A \rightarrow c(B_1, \ldots, B_k) \) where \( c \in C \) (i.e. \( c \) contains no terminal symbols) and none of \( B_1, \ldots, B_k \) is \( S \). Starting with \((G, \mu)\), we incrementally construct a lexical PLCFRS in three steps:

1. **Monic rules are removed.**
2. **Terminating rules are removed and for each branching rule, each subset of rhs nonterminals is replaced with lexical symbols of matching terminating rules.**

   This construction obtains terminating rules with at least two lexical symbols and each constructed monic rule contains at least one lexical symbol.

3. **A terminal is cut from each terminating rule and pasted into a remaining non-lexical branching rule if a derivation with the branching rule reaches the terminating rule at some point.**

   The first two steps are direct instances of the lexicalization for multiple context-free tree grammars as introduced by Engelfriet et al. (2018).

**Step 1 (Dechain).** In the first step, we remove each monic rule and chain its composition with the composition of each other reachable rule.

**Definition 1.** Let \( k \in \mathbb{N}, s, s', s_1, \ldots, s_k \in \mathbb{N}, c \in C_{(s_1, \ldots, s_k)} \) and \( c' \in C_{(s, s')} \). We denote the composition \([c'](c) \in C_{s_1 \ldots s_k s'} \) by \( c' \circ c \).

The set of rules \( R_{dc} \) is the smallest set \( \hat{R} \) such that
- \( R \setminus R^{(M)} \subseteq \hat{R} \) • for each \( A \rightarrow c_1(B) \in R^{(M)} \) and \( B \rightarrow c_2(C_1, \ldots, C_k) \in \hat{R} \), the rule \( A \rightarrow c_1 \circ c_2 (C_1, \ldots, C_k) \) is in \( \hat{R} \). We define the function \( \mu_{dc} : R_{dc} \rightarrow [0, 1] \) such that, for each rule \( r = A \rightarrow c (C_1, \ldots, C_k) \in R_{dc} \), the value is

\[ \mu_{dc}(r) = \max \{ \mu(r) \} \cup \{ \mu(r_1) \cdot \mu_{dc}(r_2) \mid r_1 = A \rightarrow c_1(B) \in R^{(M)}, \quad r_2 = B \rightarrow c_2(C_1, \ldots, C_k) \in R_{dc} : c_1 \circ c_2 = c \}. \]

The set \( R_{dc} \), as well the function \( \mu_{dc} \), can be efficiently computed with an instance of the algorithm by Aho et al. (1974, alg. 5.5), cf. alg. 1 in app. A.
Figure 2: Fusing of terminals. Left: derivation of G_{dc}. Right: corresponding derivation of G_{pt}, where the terminals of the leaves are inserted into their parent rules.

**Step 2 (Fuse Terminals).** In this step, the symbols of the terminating rules are inserted into non-terminating (terminal-free) rules. The intuition is given in Fig. 2. For the formal definition we first introduce the insertion operation.

**Definition 2.** Let \( A \rightarrow c(B_1, \ldots, B_k) \) be a rule, \( \pi \subseteq \{i \in [k] \mid B_i \in N_1 \} \) and \( \rho : \pi \rightarrow \Sigma \). Moreover, let \( i_1, \ldots, i_{k-|\pi|} \) be the indices in \([k] \setminus \pi\) in ascending order. The composition \( c[\rho] \) is obtained from \( c \) by replacing each variable of the form \( x_i^j \) by \( \rho(i) \) if \( i \in \pi \), or \( \bullet \) by \( x_i^j \) if \( i \notin \pi \). We denote \( A \rightarrow c[\rho](B_{i_1}, \ldots, B_{i_{k-|\pi|}}) \) by \( A \rightarrow c(B_1, \ldots, B_k)[\rho] \). \( \Box \)

For each rule \( r : A \rightarrow c(B_1, \ldots, B_k) \), we define the set \( F(r) = \{ \rho : \pi \rightarrow \Sigma \mid \pi \subseteq \{i \in [k] \mid B_i \in N_1 \}, \forall i \in \pi : B_i \rightarrow (\rho(i) \in R^{(T)}_{dc} \} \). It contains each function that replaces a subset of \( r \)'s rhs nonterminals with terminal symbols respecting the terminating rules; we use it to define the set of rules \( R_{pt} \) and the function \( \mu_{pt} : R_{pt} \rightarrow [0, 1] \):

\[
R_{pt} = \{ r[\rho] \mid r \in R_{dc} \setminus R^{(T)}_{dc} \setminus F(r) \}, \\
\mu_{pt}(r') = \max \left\{ \prod_{i \in \pi} \mu_{dc}(B_i \rightarrow (\rho(i))) \mid r \in R_{dc} \setminus R^{(T)}_{dc}, \rho \in F(r); r[\rho] = r' \right\}.
\]

**Step 3 (Propagate Terminals).** In this final step, terminal symbols are inserted into the remaining non-lexical branching rules. Intuitively, one terminal symbol is cut from each terminating rule, which now has at least two occurrences of terminal symbols. This symbol is then pasted into a non-lexical branching rule that reaches the rule it was cut from via its second right-hand side nonterminal. If there are rules between the terminating rule the symbol was cut from and the rule it shall be pasted into, then the information that a terminal can be pasted through these rules is propagated via the nonterminals. For this we extend the set of nonterminals to \( N_{pt} = N \cup N \times \Sigma \), where \((A, \sigma) \in N \times \Sigma \) indicates that \( \sigma \) was cut from a rule with left-hand side \( A \) (sort_{pt}(A, \sigma) = \text{sort}_{\psi}(A)\) for each \((A, \sigma) \in N \times \Sigma \).

**Fig. 3** shows an example of how the terminal symbols are propagated through a derivation.

**Definition 3.** Let \( \sigma \in \Sigma \) and \( r \) be a rule of the form \( A \rightarrow (\sigma u_1, u_2, \ldots, u_s)(B_1, \ldots, B_k) \). We denote \((A, \sigma) \rightarrow (u_1, \ldots, u_s)(B_1, \ldots, B_k)\) by \( \text{cut}(r) \). \( \Box \)

**Definition 4.** Let \( r : A \rightarrow c(B_1, \ldots, B_k) \) be a rule and \( i \in [k] \). We obtain \( r' \) from \( c \) by replacing the variable \( x_i^1 \) with \( \sigma x_i^1 \) and denote \( A \rightarrow c'(B_1, \ldots, (B_i, \sigma), \ldots, B_k) \) by \( \text{paste}_{\sigma_2}(r) \).

Let \( R_{pt}^{(T)} \) denote the set of rules in \( R_{pt} \) without terminals. We define the sets of rules

\[
R' = \{ \text{paste}_{\sigma_2}(r) \mid r \in R_{pt}^{(T)}, \sigma \in \Sigma \} \cup (R_{pt} \setminus R_{pt}^{(T)}) \\
R_{pt} = (R_{pt} \setminus R_{pt}^{(T)}) \cup R'
\]

\[
\cup \{ \text{cut}(A \rightarrow c) \mid A \rightarrow c \in R_{pt}^{(T)} \} \\
\cup \{ \text{cut(paste}_{\sigma_2}(r)) \mid r \in R' \cup R_{pt}^{(M)}, \sigma \in \Sigma \}.
\]

Note that, in contrast to Engelfriet et al. (2018), we do not need to split the rules’ compositions, because we always cut the first symbol. Therefore, the fanout of the grammar is unchanged.

The applications of cut and paste that led to a rule in \( R_{pt} \) are unambiguously determined from the lhs and rhs nonterminals in \( N \times \Sigma \). These operations are unambiguously reversible; for each \( r' \in R_{pt} \), there is a rule in \( R_{pt} \) uniquely determined such that \( r' \) is exactly one of \( \bullet \), \( \bullet \text{paste}_{\sigma_2}(r) \), \( \bullet \text{cut}(r) \), \( \bullet \text{cut(paste}_{\sigma_2}(r)) \), or \( \bullet \text{cut(paste}_{\sigma_2}(r), \text{paste}_{\sigma_2}(r)) \).

We define the function \( \mu_{pt} : R_{pt} \rightarrow [0, 1] \) such that \( \mu_{pt}(r') = \mu_{pt}(r) \) for each \( r' \in R_{pt} \).

**Theorem 5.** The PLCFRS \((N_{pt}, \Sigma, S, R_{pt}, \mu_{pt})\) and \((G, \mu)\) are \( \text{ldTT}^{R} \)-equivalent.

**4 Unlexicalizing Derivations**

The ultimate goal of parsing is to obtain derivations of the original grammar \((G, \mu)\), which are quite different from the derivations of the transformed grammar \((N_{pt}, \Sigma, S, R_{pt}, \mu_{pt})\). Therefore we seek a transformation from \( \text{TT}^{R_{pt}} \) to \( \text{TT}^{R} \).

Engelfriet et al. (2018) have introduced deterministic linear and non-deleting \( \text{TT}^{R_{pt}} \) from \( \text{TT}^{R_{dc}} \) to \( \text{TT}^{R_{dc}} \), from \( \text{TT}^{R_{dc}} \) to \( \text{TT}^{R} \); they were used to show \( \text{ldTT}^{R} \)-equivalence of the corresponding grammars. The composition of these transducers yields a transduction from \( \text{TT}^{R_{pt}} \) to \( \text{TT}^{R} \). However, for recovering derivations, these transducers are not adequate, as a derivation in \( \text{TT}^{R_{dc}} \) or \( \text{TT}^{R} \) may have multiple possible originals in \( \text{TT}^{R_{dc}} \) or \( \text{TT}^{R} \), respectively. We want to be able to obtain all of these derivations, as this may be beneficial for
later stages of an application (e.g., when selecting \( k \) best derivations is desired).

For this, we employ two approaches. We map each derivation in \( T^G_{pt} \) to its unique original derivation by using the transducer of (Engelfriet et al., 2018); we denote this transducer by \( T^-_{pt} \). It realizes a deterministic tree relabeling which is already indicated at the end of the previous section. For the other two transductions, we define novel non-deterministic tree transducers.

**Transduction** \( T^R_0 \rightarrow T^R_{dc} \). Let \( r = A \rightarrow c(B_1, \ldots, B_k) \in R_{ft}, \pi \subseteq \{ i \in [k] | B_i \in N_i \} \), \( R: \pi \rightarrow \Sigma \) and \( i_1, \ldots, i_{k-|\pi|} \) be the elements of \( [k] \setminus \pi \) in ascending order. We denote the tree \( r(d_1, \ldots, d_k) \), where \( d_i = B_i \rightarrow (r(i)) \) if \( i \in \pi \) and \( d_i = *(x_i) \) if \( i = i_\ell \), by \( r(x_1, \ldots, x_k)[|\rho|] \).

We define the linear and non-deleting TT \( T^-_{dc} = (\{\ast\}, R_{ft}, R_{dc}, \ast, \delta) \), where \( \delta \) is the smallest set such that, for each rule \( r = A \rightarrow c(B_1, \ldots, B_k) \in R_{dc} \setminus R_{dc}^T \) and \( \rho \in F(r) \), the transition \( *\rho r(x_1, \ldots, x_k-[|\pi|]) \rightarrow r(x_1, \ldots, x_k)[|\rho|] \) is in \( \delta \).

**Transduction** \( T^R_{dc} \rightarrow T^R \). Let us denote the composition \( (x_1, \ldots, x_{\text{sort}(A)}) \) by \( \text{id}_A \) for each \( A \in N \). We define the linear and non-deleting \( \epsilon \)TT \( T^-_{dc} = (Q, R_{dc}, R, (S, \text{id}_S), \delta) \) where

\[
Q = \bigcup_{A,B \in N} [B] \times C_{\text{sort}(B),\text{sort}(A)} \quad \text{and} \quad \delta \text{ is the smallest set that contains,}
\]

- for each \( (B, c) \in Q, r = B \rightarrow c'(B_1, \ldots, B_k) \in R \setminus R^M \) and \( A \in N \), the transition \( (\text{id}_B, d_{1})(x_1), \ldots, (\text{id}_B, d_k)(x_k) \),

- for each \( (A, c) \in Q \) and \( r = A \rightarrow c'(B) \in R^M \), the transition \( (A, c)(x_1) \rightarrow r((B, c \circ c')(x_1)) \).

The transduction \( T^-_{dc} \circ T^-_{dc} \circ T^-_{dc} : T^R_{dc} \rightarrow T^R \), i.e., the composition of the three transductions introduced in this section, is the inverse of the transduction \( T^- \) from the proof of Theorem 5 (cf. App. B, p. 7). Therefore, the \( k \) best derivations in \((G, \mu)\) must be among the transductions of the \( k \) best derivations in \((N_{pt}, \Sigma, S, R_{pt}, \mu_{pt})\), which benefits the enumeration of \( k \) best derivations.

5 Conclusion

Based on Engelfriet et al. (2018), we have introduced a procedure which constructs for every PLCFRS \( G \) an equivalent lexicalized PLCFRS \( G'. \) Moreover, we have described how to recover from each derivation of \( G' \) all corresponding derivations of \( G \). In future work, we will use our approach to implement a supertagging-based LCFRS parser.

23. return $(R', \mu')$

B Supplemental Proofs

We prove thm. 5 in two steps.

First lem. 7 shall prove that the (unweighted) underlying grammars, $G$ and $(N_{pt}, \Sigma, S, R_{pt})$ are lDTTR-equivalent. As linear and deterministic TT are closed under composition, the idea is to construct two of them for each step, one that transduces derivations in the original to derivations in the constructed grammar and vice versa. The three transducers for each direction are then composed to obtain transductions from derivations in $G$ to derivations in $(N_{pt}, \Sigma, S, R_{pt})$ and vice versa.

Thm. 5 additionally proves the preservation of the weights. Similarly to the above, we show that the PLCFRS constructed in each of the three steps are lDTTR-equivalent. The property is clearly transitive.

Definition 6. A TT is a tuple $A = (Q, \Sigma, \Lambda, q_1, \delta)$ where $Q, \Sigma, \Lambda$ and $q_1$ are as in TT, and transitions in $\delta$ are of the form $q(\sigma(x_1 : L_1, ..., x_k : L_k) : L_0) \rightarrow t$ where $q \in Q, \sigma \in \Sigma, t \in T^{(T)(Q(x_1, ..., x_k))}$ and $L_0, ..., L_k$ are regular tree languages.

We omit some of the languages $L_0, ..., L_k$ if they are $T^{(T)}$. We define the binary relation $\Rightarrow$ over $T^{(T)}(Q(T))$ such that $s \Rightarrow t$ if there is a subtree $q(\sigma(s_1, ..., s_k))$ in $s$ and a transition $q(\sigma(x_1 : L_1, ..., x_k : L_k) : L_0) \rightarrow t'$ such that $\bullet s_1, ..., s_k \bullet \in L_0, s_1 \in L_1, ..., s_k \in L_k$, and $\bullet t$ is obtained by replacing $q(\sigma(s_1, ..., s_k))$ in $s$ by $t'$ and replacing $x_i$ by $s_i$ for each $i \in [k]$.

Lemma 7. The LCFRS $G$ and $(N_{pt}, \Sigma, S, R_{pt})$ are lDTTR-equivalent.

Proof. The first two steps are instances of lems. 32 and 37 by Engelfriet et al. (2018), therefore we will only show the third step.

Step 3. For the construction, we consider $R_0$ and $R_{pt}$ as ranked sets. For each $R \in \{R_{pt}, R_{pt}\}$ and rule of the form $r = A \rightarrow c(B_1, ..., B_k) \in R$, we let $r_k(r) = k$.

Let, for each $\sigma \in \Sigma, R_0$ and $R_{pt}$ be the sets of all rules in $R_0$ of the form $A \rightarrow c(B_1, ..., B_k)$ where $c$ is of the form $(\sigma u_1, u_2, ..., u_k)$ and $(x_1^1 u_1, u_2, ..., u_k)$, respectively. To decide whether a terminal symbol may be propagated through a derivation, we define the look-ahead language $L_{\sigma}$

\footnote{Regular tree languages are recognized by regular tree automata. We refer to Maletti and Satta (2009) for an overview.}
for each \( \sigma \in \Sigma \) as the smallest set \( L \) such that
\[
L = \{ r(d_1, \ldots, d_k) \mid r \in R_\sigma, d_1, \ldots, d_k \in \mathbb{T}^R \} \\
\cup \{ r(d_1, \ldots, d_k) \mid r \in R_d, d_1, \ldots, d_k \in L, \}
\]
\[
d_2, \ldots, d_k \in \mathbb{T}^R. \]

**Observation 8.** Let \( d \in \mathbb{T}^R \) and \( \sigma \in \Sigma \). The following are equal: 1. \( d \in L_\sigma \), and 2. \( yd(d) \) is of the form \((\sigma u_1, u_2, \ldots, u_\kappa)\).

We define the \( \text{ldTT}^R \) \( T \) by \( (\{p, \ast\}, R_{\text{ft}}, R_{\text{pt}}, \ast, \delta) \) where \( \delta \) contains the following transitions

1. \( *(r(x_1, \ldots, x_k)) \rightarrow r(*(x_1), \ldots, *(x_k)) \) for each \( r \in R_{\text{ft}} \setminus R_{\text{ft}(X)} \),
2. for each \( r \in R_{\text{ft}(X)} \), \( *(r(x_1, x_2; L_\sigma, x_3, \ldots, x_k)) \rightarrow \text{paste}_{\sigma}^2(r)(*(x_1), p(x_2), *(x_3), \ldots, *(x_k)) \),
3. \( p(r) \rightarrow \text{cut}(r) \) for each \( r \in R_{\text{ft}}^T \),
4. for \( r \in R_{\text{ft}}(M) \cup (R_{\text{ft}}^B \setminus R_{\text{ft}}^T) \) and \( \sigma \in \Sigma \), \( p(r(x_1; L_\sigma, x_2, \ldots, x_k)) \rightarrow \text{cut}(\text{paste}_{\sigma}(r)) \ast (p(x_1), *(x_2), \ldots, *(x_k)) \), and
5. for each \( r \in R_{\text{ft}}(X) \) and \( \sigma_1, \sigma_2 \in \Sigma \), \( p(r(x_1; L_{\sigma_1}, x_2; L_{\sigma_2}, x_3, \ldots, x_k)) \rightarrow r'(p(x_1), p(x_2), *(x_3), \ldots, *(x_k)) \) where \( r' = \text{cut}(\text{paste}_{\sigma_1}(\text{paste}_{\sigma_2}(r))) \).

Let us have a close look at some constructions in these transitions. Let \( r = A \rightarrow c(B_1, \ldots, B_\kappa) \) be a rule and \( (v_i \in (\Sigma^*)^n)_{i \in [k]} \). We denote the composition of \( \text{cut}(r) \) by \( \text{cut}(c) \) and the composition of \( \text{paste}_{\sigma}^i(r) \) by \( \text{paste}_{\sigma}^i(c) \).

**Observation 9.** Let \( \text{cut}(c) \) be defined, then \( \llbracket \text{cut}(c) \rrbracket((v_1, \ldots, v_\kappa)) = \text{cut}(\llbracket c \rrbracket((v_1, \ldots, v_\kappa))) \).

**Observation 10.** Let \( v_i \) be of the form \((\sigma u_1, u_2, \ldots, u_\kappa)\) for \( i \in [k] \) and \( \sigma \in \Sigma \). \( \llbracket \text{paste}_{\sigma}^i(c) \rrbracket((v_1, \ldots, \text{cut}(v_i), \ldots, v_\kappa)) = \llbracket c \rrbracket((v_1, \ldots, v_\kappa)) \).

Using the observations 8–10 one can easily show that, for each \( d \in \mathbb{T}^R \) and \( d' \in \mathbb{T}^R \): 1. if \( *(d) \Rightarrow_{I_{\text{pt}}}^* d' \), then \( yd(d) = yd(d') \), and 2. if \( p(d) \Rightarrow_{I_{\text{pt}}}^{*} d' \), then \( yd(d') = (u_1, \ldots, u_\kappa) \) and \( d \in L_\sigma \) where \((\sigma u_1, \ldots, u_\kappa) = yd(d) \). This concludes the proof in the direction \( \mathbb{T}^R \rightarrow \mathbb{T}^R \).

For the other direction, we observe that the applications of \( \text{cut} \) and \( \text{paste} \) to obtain the rules in \( R_{\text{pt}} \) can easily be determined by the occurrences of the nonterminals in \( N \times \Sigma \). The transduction \( \mathbb{T}^R_{\text{pt}} \rightarrow \mathbb{T}^R \) is thus a deterministic relabeling and can be implemented by a deterministic top-down tree transducer. Engelfriet et al. (2018, lem. 42, pg. 39) came to the same conclusion for their construction.

**Theorem 5.** The PLCFRS \( ((N_{\text{pt}}, \Sigma, R_{\text{pt}}), \mu_{\text{pt}}) \) and \( (G, \mu) \) are \( \text{ldTT}^R \)-equivalent.

**Proof sketch.** We split the proof into the two remaining properties to show:

1. \( \text{wt}(\llbracket T \rrbracket(d)) \geq \text{wt}(d) \) for each \( d \in \mathbb{T}^R \), and
2. \( \text{wt}(\llbracket T' \rrbracket(d')) \geq \text{wt}(d')^2 \) for each \( d' \in \mathbb{T}^R \).

**item 1** The weight functions in sec. 3 are obviously defined in such a way that the weight of a constructed rule is the greatest product of weights for all involved rules in the construction. For each step, the transducer \( T \) replaces the rules in the derivation \( d \) with an unambiguous constructed rule (this follows from the inductive structure of the previous proof). Therefore, the weight \( \text{wt}(\llbracket T \rrbracket(d)) \) must be greater than \( \text{wt}(d) \).

**item 2** For each step, the transducer \( T' \) gives us some derivation that contains the rules that were used to construct the rules in \( d' \). The construction of \( T' \) for the steps 1 and 2 is ambiguous, so that we can choose any combination of rules used to construct \( r' \) for each rule \( r' \) in \( d' \). \( \llbracket T' \rrbracket(d') \) then contains each rule in these combinations. Intuitively, we choose the combination of rules with greatest product of weights. Then the weight \( \text{wt}(\llbracket T' \rrbracket(d')) \) is \( \text{wt}(d') \).

---

\(^{2}\)More specifically, we prove \( \text{wt}(\llbracket T' \rrbracket(d')) = \text{wt}(d') \) for each \( d' \in \mathbb{T}^R \).
