TILTING THEORY AND CLUSTER COMBINATORICS

ASLAK BAKKE BUAN, ROBERT MARSH, MARKUS REINEKE, IDUN REITEN, AND GORDANA TODOROV

Abstract. We introduce a new category $\mathcal{C}$, which we call the cluster category, obtained as a quotient of the bounded derived category $\mathcal{D}$ of the module category of a finite-dimensional hereditary algebra $H$ over a field. We show that, in the simply-laced Dynkin case, $\mathcal{C}$ can be regarded as a natural model for the combinatorics of the corresponding Fomin–Zelevinsky cluster algebra. In this model, the tilting modules correspond to the clusters of Fomin–Zelevinsky. Using approximation theory, we investigate the tilting theory of $\mathcal{C}$, showing that it is more regular than that of the module category itself, and demonstrating an interesting link with the classification of self-injective algebras of finite representation type. This investigation also enables us to conjecture a generalisation of APR-tilting.

Introduction

In this paper, we introduce a new category, which we call the cluster category, associated with any finite dimensional hereditary algebra $H$ over a field $k$. This is defined as the quotient $\mathcal{C}$ of the bounded derived category $\mathcal{D}$ of finitely generated modules over $H$ by the functor $F = \tau^{-1}[1]$, where $\tau$ denotes the AR-translation and $[1]$ denotes the shift functor. The category $\mathcal{C}$ is triangulated, by a result of Keller [K], and we show that it is also a Krull-Schmidt category. Our main aims are to show how this category can be used to study the tilting theory of $H$ (and related algebras) and to show that it can be used as a model for the combinatorics of an associated Fomin–Zelevinsky [FZ] cluster algebra.

Hom-configurations are certain collections of non-isomorphic indecomposable objects in $\mathcal{D}$, and were considered in [Rie1] in connection with the classification of self-injective algebras of finite representation type. We formulate analogous conditions using $\text{Ext}^1$ instead of $\text{Hom}$, and call the resulting collections Ext-configurations. We show that they exhibit a behaviour similar to that of Hom-configurations. In particular, they are invariant under the functor $F$ (compare [BLR], where it is shown that Hom-configurations exhibit a similar kind of invariance in the Dynkin case). As a consequence, we can show that they are in 1–1 correspondence with basic tilting objects in $\mathcal{C}$. By showing that a basic tilting object in $\mathcal{C}$ is induced by a basic tilting module over some hereditary algebra derived equivalent to $H$, we prove that Ext-configurations, like Hom-configurations in the Dynkin case, are induced by basic tilting modules.

The category $\mathcal{C}$ provides an interesting “extension” of the module category of $H$. It is known that any almost complete basic tilting module $\mathcal{T}$ over $H$ can be...
completed to a basic tilting module in at most two different ways \[ \text{[RS1, U1]} \] and in exactly two different ways if and only if \( \mathbf{T} \) is sincere \[ \text{[HUI]} \]. However, in the extended category \( \mathcal{C} \), the behaviour is more regular: an almost complete basic tilting object always has exactly two complements. We show further that, given one complement \( M \) to an almost complete basic tilting object \( \mathbf{T} \), the other can be constructed using approximation theory from \[ \text{[AS]} \]. Indeed, we show that there is a triangle

\[
M^* \rightarrow B \rightarrow M \rightarrow M^*[1]
\]

in \( \mathcal{C} \), where \( B \rightarrow M \) is a minimal right \( \mathbf{T} \)-approximation of \( M \) in \( \mathcal{C} \) and \( M^* \) is the other complement to \( \mathbf{T} \). Dually, there is a triangle

\[
M \rightarrow B' \rightarrow M^* \rightarrow M[1]
\]

in \( \mathcal{C} \). In fact, we are able to show that two indecomposable objects \( M \) and \( M^* \) form such an exchange pair if and only if

\[
\dim \text{End}_M \mathcal{E}xt^1_M(M, M^*) = 1 = \dim \text{End}_{M^*} \mathcal{E}xt^1_M(M^*, M).
\]

The above results have some interesting interpretations in the Dynkin case in terms of cluster algebras, which were defined by Fomin and Zelevinsky \[ \text{[FZ1]} \]. These algebras were defined so that the cluster structure (when quantised) should encode multiplicative properties of the dual canonical basis of the quantised enveloping algebra of a semisimple Lie algebra over \( \mathbb{C} \), and that it should model the (classical and quantised) coordinate rings of varieties associated to algebraic groups (now shown in several cases — see \[ \text{[FZ3, S]} \]), with particular relevance to total positivity properties; there have already been many applications to other areas as well \[ \text{[CFZ, FZ3, FZ4, FZ5, GSV, MRZ, P]} \].

The definition is as follows. Let \( \mathbb{F} = \mathbb{Q}(u_1, u_2, \ldots, u_n) \) be the field of rational functions in indeterminates \( u_1, u_2, \ldots, u_n \). Let \( x \subseteq \mathbb{F} \) be a transcendence basis over \( \mathbb{Q} \), and let \( B = (b_{xy})_{x,y \in x} \) be an \( n \times n \) sign-skew-symmetric integer matrix with rows and columns indexed by \( x \). In other words, we suppose that for all \( x, y \in x \), \( b_{xy} = 0 \) if and only if \( b_{yx} = 0 \), that \( b_{xx} = 0 \) if and only if \( b_{xx} = 0 \), and that \( b_{xx} = 0 \).

Such a pair \((x, B)\) is called a seed. Fomin and Zelevinsky \[ \text{[FZ1, FZ2]} \] have defined a certain subring \( \mathcal{A}(x, B) \) of \( \mathbb{F} \) associated to the seed \((x, B)\), known as a cluster algebra. Given such a seed, and an element \( z \in x \), define a new element \( z' \in \mathbb{F} \) via the binary exchange relation:

\[
zz' = \prod_{x \in x, b_{xz} = 0} x^{b_{xz}} + \prod_{x \in x, b_{xz} < 0} x^{-b_{xz}}.
\]

In such circumstances, we say that \( z, z' \) form an exchange pair. Let \( x' = x \cup \{z'\} \setminus \{z\} \), a new transcendence basis of \( \mathbb{F} \). Let \( B' \) be the mutation of the matrix \( B \) in direction \( z \) (as defined in \[ \text{[FZ1]} \]). Then

\[
b'_{xy} = \begin{cases} 
-b_{xy} & \text{if } x = z \text{ or } y = z, \\
b_{xy} + \frac{1}{2}(b_{zx}b_{zy} + b_{xz}b_{zy}) & \text{otherwise.}
\end{cases}
\]

The row and column labelled \( z \) in \( B \) are relabelled \( z' \) in \( B' \). The pair \((x', B')\) is called the mutation of the seed \( x \) in direction \( z \). Let \( \mathcal{S} \) be the set of seeds obtained by iterated mutation of \((x, B)\). Then the set of cluster variables is, by definition, the union \( \chi \) of the transcendence bases appearing in the seeds in \( \mathcal{S} \), and the cluster algebra \( \mathcal{A}(x, B) \) is the subring of \( \mathbb{F} \) generated by \( \chi \). Up to isomorphism of cluster algebras, it does not depend on the initial choice \( x \) of transcendence basis, so can be denoted \( \mathcal{A}_B \). In general, coefficients appear in the relation \[ \text{[II]} \], but here we take all of these coefficients to be 1 as this is enough to describe the connections with representation theory that we consider.

If its matrix is skew-symmetric, a seed \((x, B)\) determines a quiver with vertices corresponding to its rows and columns, and \( b_{ij} \) arrows from vertex \( i \) to vertex \( j \)
whenever $h_{ij} > 0$. If $\chi$ is finite, the cluster algebra $A_B$ is said to be of finite type. In [FZ2], it is shown that, up to isomorphism, the cluster algebras of finite type can be classified by the Dynkin diagrams; they are precisely those for which there exists a seed whose corresponding quiver is of Dynkin type. In this case, Fomin and Zelevinsky associate a nonnegative integer, known as the compatibility degree, to each pair of cluster variables (see Section 4). Two variables are said to be compatible provided that their compatibility degree is zero, and clusters are maximal compatible subsets of $\chi$.

Suppose that $H$ is the path algebra of a simply-laced Dynkin quiver of type $\Delta$. We show that the indecomposable objects in $C$ are in 1–1 correspondence with the cluster variables in a cluster algebra $A$ of type $\Delta$. Using results from [MRZ], we show that, for the two indecomposable objects $X, Y$ in $C$, $\dim \text{Ext}^1_C(X, Y)$ is equal to the compatibility degree of the corresponding cluster variables.

The advantage of our approach here is that it allows us to give a direct interpretation of all clusters in terms of tilting objects: it follows from the above that the clusters of $A$ are in 1–1 correspondence with the basic tilting objects in $C$. We develop this relationship further: the existence of exactly two complements for any almost complete basic tilting object in $C$ then corresponds to the fact that for any almost complete cluster there are exactly two ways to complete it to a cluster (by adding a cluster variable). A consequence of our result above is a new proof of the result [FZ2, 3.5,4.4] that two cluster variables form an exchange pair (i.e. appear in an exchange relation — see equation (1)) if and only if their compatibility degree is 1. We conjecture that in this case the middle term $B$ in the triangle above is the direct sum of the indecomposable objects corresponding to the cluster variables appearing in one term of the exchange relation [FZ2, 1.1], with the middle term $B'$ of the dual triangle corresponding to the other term (see Conjecture 9.3), suggesting that it might be possible to construct the cluster algebra directly from $C$. Finally, we are able to use the new perspective on tilting theory afforded by cluster algebras and the cluster category to conjecture a generalisation of APR-tilting (see [APR]).

P. Caldero, F. Chapoton and R. Schiffler [CCS] have recently associated a category to the cluster algebra of type $A_n$, giving a definition via the combinatorics of the corresponding cluster algebra. They have shown that this category is equivalent to the cluster category $C$ we have associated to a Dynkin quiver of type $A_n$. Their approach enables them to generalise the denominator theorem of Fomin and Zelevinsky [FZ2, 1.9] to an arbitrary cluster. Instead, in our approach we consider a more general situation (an arbitrary finite dimensional hereditary algebra), and the connections with tilting theory and configurations of modules in the derived category. We develop links with cluster combinatorics for all simply-laced Dynkin cases in a uniform way.

1. Cluster categories

In this section we introduce what we call the cluster category of a finite dimensional hereditary algebra, and discuss some of its elementary properties.

Let $H$ be a finite dimensional hereditary algebra over a field $k$, and denote by $\mathcal{D} = D^b(H)$ the bounded derived category of finitely generated $H$-modules with shift functor $[1]$. For any category $\mathcal{E}$, we will denote by $\text{ind} \mathcal{E}$ the subcategory of isomorphism classes of indecomposable objects in $\mathcal{E}$; depending on the context we shall also use the same notation to denote the set of isomorphism classes of indecomposable objects in $\mathcal{E}$.

Let $G: \mathcal{D} \to \mathcal{D}$ be a triangle functor, which we also assume satisfies the following properties; see [K].
(g1) For each $U$ in $\text{ind} \, H$, only a finite number of objects $G^nU$, where $n \in \mathbb{Z}$, lie in $\text{ind} \, H$.

(g2) There is some $N \in \mathbb{N}$ such that $\{U[n] \mid U \in \text{ind} \, H, n \in [-N,N]\}$ contains a system of representatives of the orbits of $G$ on $\text{ind} \, D$.

We denote by $D/G$ the corresponding factor category. The objects are by definition the $G$-orbits of objects in $D$, and the morphisms are given by

$$\text{Hom}_{D/G}(\tilde{X}, \tilde{Y}) = \prod_{i \in \mathbb{Z}} \text{Hom}_D(G^iX, Y).$$

Here $X$ and $Y$ are objects in $D$, and $\tilde{X}$ and $\tilde{Y}$ are the corresponding objects in $D/G$ (although we shall often write such objects simply as $X$ and $Y$). Note that it follows from our assumptions on $G$ that $\text{Hom}_D(G^iX, Y) \neq 0$ for only a finite number of values of $i$. It is known from [K] that $D/G$ is a triangulated category and that the natural functor $\pi : D \to D/G$ is a triangle functor. The shift in $D/G$ is induced by the shift in $D$, and is also denoted by $[1]$. In both cases we write as usual $\text{Hom}(U, V[1]) = \text{Ext}^1(U, V)$. We then have

$$\text{Ext}_{D/G}(\tilde{X}, \tilde{Y}) = \prod_{i \in \mathbb{Z}} \text{Ext}^1_D(G^iX, Y),$$

where $X, Y$ are objects in $D$ and $\tilde{X}, \tilde{Y}$ are the corresponding objects in $D/G$. Note that since there are only finitely many values of $i$ such that $\text{Hom}_D(G^iX, Y)$ is not zero, there are also only finitely many values of $i$ such that $\text{Ext}^1_D(G^iX, Y)$ is not zero, for $X, Y$ in $D$. We remark that the quotient $D^b(H)/[2]$ was considered in [H1]; however, this quotient has quite different properties and is not closely linked with cluster algebras.

While several properties hold for arbitrary functors $G$ satisfying (g1) and (g2), we shall mainly be concerned with the special choice of functor $F = \tau^{-1}[1]$, where $\tau$ is the AR-translation in $D$ (which is induced by $D\text{Tr}$ on non-projective indecomposable objects in $\text{ind} \, H$, and where $\tau(P) = I[-1]$ when $P$ is indecomposable projective and $I$ denotes the indecomposable injective with $\text{soc} I \simeq P/I P$).

We shall see various reasons why the factor category $D/F$ is especially nice. Because of the applications to cluster theory we call it the cluster category of $H$, and we denote it by $\mathcal{C}$.

If we are in the setting with $H$ of finite representation type and $k$ an algebraically closed field, then $D$ (and thus $\mathcal{C}$) only depends on the underlying graph $\Delta$ of the quiver of $H$, and we write $\mathcal{C} = \mathcal{C}(\Delta)$. Then $\Delta$ is a simply-laced Dynkin diagram. For this case we give a combinatorial construction of $\text{ind} \, \mathcal{C}$. We recall the theory of translation quivers from [Ri1,2]. If $\Gamma = (\Gamma_0, \Gamma_1)$ is any quiver, with vertices $\Gamma_0$ and arrows $\Gamma_1$, we recall that, if $x \in \Gamma_0$, then $x^+$ is the set of the end-points of arrows which start at $x$, while $x^-$ denotes the set of starting points of arrows which end at $x$. A stable translation quiver is a quiver $\Gamma$, without any loops or multiple edges, together with a bijection $\tau : \Gamma_0 \to \Gamma_0$ (known as the translation) such that, for all $x \in \Gamma_0$, $x^- = \tau(x)^+$. A morphism of stable translation quivers is defined to be a quiver morphism which commutes with translation.

If $\Gamma$ is a stable translation quiver, and $a : x \to y$ is an arrow of $\Gamma$, then there is a unique arrow $\sigma(a) : \tau(y) \to x$. The rule $a \mapsto \sigma(a)$ defines a bijection from $\Gamma_1$ to $\Gamma_1$, known as the polarisation. The mesh category associated to $\Gamma$ has objects indexed by the vertices of $\Gamma$, and morphisms generated by the arrows of $\Gamma$, subject to the mesh relations (for all vertices $y$ of $\Gamma$):

$$\sum_{a : x \to y} \sigma(a)a = 0.$$
If $\mathcal{E}$ is a Krull-Schmidt category with almost split sequences, we shall denote its AR-quiver by $\Gamma(\mathcal{E})$ (see [Rin]).

Let $Q$ be the quiver of $H$ and let $\mathbb{Z}Q$ be the stable translation quiver associated to $Q$ (see [Ri2]). The vertices of $\mathbb{Z}Q$ are labelled by pairs $(n, i)$ with $n$ in $\mathbb{Z}$ and $i$ a vertex of $Q$. Whenever there is an arrow in $Q$ from $i$ to $j$ there is an arrow from $(n, i)$ to $(n, j)$, and an arrow from $(n, j)$ to $(n + 1, i)$, and these are all the arrows in $\mathbb{Z}Q$. A translation $\tau$ is defined on $\mathbb{Z}Q$, just taking $(n, i)$ to $(n - 1, i)$. In this way $\mathbb{Z}Q$ is a stable translation quiver. We denote the corresponding mesh category by $k(\mathbb{Z}Q)$. We have the following:

**Proposition 1.1.** (Happel [H2, 5.6]) Let $Q$ be any quiver of Dynkin type. Then the mesh category $k(\mathbb{Z}Q)$ is equivalent to $\text{ind} \mathcal{D}$.

It follows that (as a stable translation quiver), $\mathbb{Z}Q$ depends only on the underlying Dynkin diagram $\Delta$, and not on $Q$. We therefore denote it $\mathbb{Z}\Delta$, and denote the corresponding mesh category by $k(\mathbb{Z}\Delta)$. The AR-quiver of $\mathcal{D}$ is $\Gamma(\mathcal{D}) = \mathbb{Z}\Delta$.

We recall that $F = \tau^{-1}[1]$ is an autoequivalence of $\mathcal{D}$, and therefore permutes the indecomposable objects, inducing a graph automorphism $\varphi$ (via Proposition 1.1) of $\mathbb{Z}\Delta$. We note that the graph automorphisms induced by $\tau^{-1}$ and $[1]$ are independent of the orientation $Q$, so $\varphi$ is independent of $Q$. Since $F$ commutes with $\tau$ on $\mathcal{D}$, $\varphi$ is an automorphism of stable translation quivers. It follows that the quotient graph $\mathbb{Z}\Delta/\varphi$ is also a stable translation quiver, and we can form the corresponding mesh category; this is equivalent to the category $\text{ind} C(\Delta)$ defined above. The natural epimorphism of stable translation quivers $\tau : \mathbb{Z}\Delta \to \mathbb{Z}\Delta/\varphi$, taking the vertex $v$ of $\mathbb{Z}\Delta$ to its $\varphi$-orbit $\pi(v)$, induces the functor $\pi$ above.

**Example.** In Figure 1 we show the AR-quiver of $\mathcal{C}$ in type $A_3$. The objects 1, 2 and 3 are identified with $1'$, $2'$ and $3'$ (so that, in some sense, the quotient is a Möbius strip).

![Figure 1](attachment:image.png)

**Figure 1.** The AR-quiver of $\mathcal{C}$ in type $A_3$

We are mostly interested in the factor $\mathcal{C} = \mathcal{D} / F$, where $F = \tau^{-1}[1]$. The next properties, however, we state and prove in a more general setting.

**Proposition 1.2.** Let $\mathcal{D} = \mathcal{D}^b(H)$ for a finite dimensional hereditary $k$-algebra $H$, and let $G : \mathcal{D} \to \mathcal{D}$ be a triangle functor satisfying (g1) and (g2). Then the triangulated category $\mathcal{D} / G$ is a Krull-Schmidt category.

**Proof.** Let $\tilde{X}$ be in $\mathcal{D} / G$ induced by $X$ in $\mathcal{D}$. We know that $X = X_1 \amalg \cdots \amalg X_n$ in $\mathcal{D}$, where each $X_i$ is indecomposable, with local endomorphism ring. Since the functor $\pi : \mathcal{D} \to \mathcal{D} / G$ commutes with finite direct sums, we have $\tilde{X} = \tilde{X}_1 \amalg \cdots \amalg \tilde{X}_n$.

We then claim that $\text{End}_{\mathcal{D} / G}(\tilde{X}_i)$ is local for each $i$. So let $Y$ be in $\text{ind} \mathcal{D}$. By definition, $\text{Hom}_{\mathcal{D} / G}(\bar{Y}, \bar{Y}) = \bigoplus_{i \in \mathbb{Z}} \text{Hom}_{\mathcal{D}}(G^i Y, Y)$. It is easy to see that

$$\text{rad}(Y, Y) \bigoplus \bigoplus_{i \neq 0} \text{Hom}_{\mathcal{D}}(G^i Y, Y)$$

is a unique maximal ideal in $\text{Hom}_{\mathcal{D} / G}(\bar{Y}, \bar{Y})$, which is hence a local ring. Thus, $\mathcal{D} / G$ is a Krull-Schmidt category. \(\square\)
We remark that triangles in $\mathcal{D}/G$ are not necessarily induced by those in $\mathcal{D}$. However, we have the following:

**Proposition 1.3.** Let $\mathcal{D} = D^b(H)$ for a finite dimensional hereditary $k$-algebra $H$, and let $G : \mathcal{D} \to \mathcal{D}$ be a triangle functor satisfying (g1) and (g2). Then $\mathcal{D}/G$ has almost split triangles induced by those in $\mathcal{D}$, and the AR-quiver is $\Gamma(\mathcal{D})/\varphi(G)$, where $\varphi$ is the graph automorphism induced by $G$.

**Proof.** Let $\tilde{X}$ be an indecomposable object in $\mathcal{D}/G$, induced by $X$ in $\mathcal{D}$. Let

$$\tau X \xrightarrow{\tilde{f}} E \xrightarrow{\tilde{g}} X \xrightarrow{\tau} \tau X[1]$$

be an almost split triangle in $\mathcal{D}$. Since $\pi : \mathcal{D} \to \mathcal{D}/G$ is a triangle functor, there is the induced triangle

$$(\mathcal{D}/G)$$

in $\mathcal{D}/G$. Since $s \neq 0$, we clearly have $\tilde{s} \neq 0$. Let $\tilde{Z}$ be in $\text{ind}\mathcal{D}/G$, induced by $Z$ in $\text{ind}\mathcal{D}$, with $\tilde{Z} \not\simeq \tilde{X}$, and let $\tilde{h} : \tilde{Z} \to \tilde{X}$ be nonzero. Then $\tilde{h} = \bigsqcup h_i$, with $h_i \in \text{Hom}_D(G^iZ,X)$. Since $\tilde{Z} \not\simeq \tilde{X}$, we have $G^iZ \not\simeq X$ for all i and hence there is some $t_i : G^iZ \to E$ such that $gt_i = h_i$. Let $\tilde{t} = \bigsqcup t_i$. Then we have $\tilde{g}\tilde{t} = \tilde{h}$, and hence $\tilde{g}$ is right almost split. Similarly $\tilde{f}$ is a left almost split map, and hence $\mathcal{D}/G$ is an almost split triangle, and the translation $\tilde{\tau}$ in $\mathcal{D}/G$ is given by $\tilde{\tau}X = \tau X$. Hence it also follows that $\Gamma(\mathcal{D})/\varphi$ is the AR-quiver for $\mathcal{D}/G$. \qed

Let $\mathcal{D} = \text{Hom}_k(\ , k)$. It is also useful to note that the Serre duality formula

$$D \text{Ext}^1_D(A,B) \simeq \text{Hom}_D(A,\tau B),$$

valid in $D^b(H)$, induces an analogous formula for $\mathcal{D}/G$.

**Proposition 1.4.** Let the notation and assumptions be as above. Then for $\tilde{X}$ and $\tilde{Y}$ in $D^b(H)/G$ we have the Serre duality formula:

$$D \text{Ext}^1_D(\tilde{X},\tilde{Y}) \simeq \text{Hom}_G(\tilde{Y},\tilde{\tau}X)$$

functorial in both $\tilde{X}$ and $\tilde{Y}$.

**Proof.** We have

$$\text{Ext}^1_D(\tilde{X},\tilde{Y}) = \bigsqcup_i \text{Hom}_D(G^iX,Y[1]) = \bigsqcup_i \text{Ext}^1_D(G^iX,Y)$$

and $\text{Hom}_D(G^iY,\tau X) = \bigsqcup_i \text{Hom}_D(G^iY,\tau X)$. We then apply the corresponding formula for $D^b(H)$. \qed

We end this section with some properties of $\mathcal{C}$. Let $\mathcal{S} = \text{ind}(\text{mod} H \vee H[1])$, i.e. the set consisting of the indecomposable $H$-modules, together with the objects $P[1]$, where $P$ is an indecomposable projective $H$-module. Then it can be seen that $\mathcal{S}$ is a fundamental domain for the action of $F$ on $\text{ind}\mathcal{D}$, containing exactly one representative from each $F$-orbit on $\text{ind}\mathcal{D}$. We recall that there is an oriented graph structure on $\text{ind}\mathcal{D}$, with an arrow from object $X$ to object $Y$ if there is a non-zero map from $X$ to $Y$.

**Proposition 1.5.** Let $X$ and $Y$ be objects in $\mathcal{S}$.

(a) We have $\text{Hom}_\mathcal{D}(F^iX,Y) = 0$ for all $i \neq -1, 0$.

(b) If $X$ or $Y$ does not lie on an oriented cycle in $\mathcal{D}$, then $\text{Hom}_\mathcal{D}(F^iX,Y) \neq 0$ for at most one value of $i$. 
Proof. (a) We have $\text{Hom}_D(F^iX, Y) = \text{Hom}_D(\tau^{-i}X[i], Y)$. For $i \geq 1$, we clearly have $\text{Hom}_D(\tau^{-i}X[i], Y) = 0$. This is obvious for $i > 1$, and for $i = 1$ we only have to consider the case $Y = P[1]$ for $P$ an indecomposable projective $H$-module. In that case we have $\text{Hom}_D(\tau^{-1}X, P)$, which must be 0. For $i \leq -2$ we have that $\text{Hom}_D(\tau^{-i}X[i], Y) = \text{Ext}_D^i(\tau^{-i}X, Y) = 0$.

(b) We have $\text{Hom}_D(F^{-1}X, Y) = \text{Hom}_D(\tau X[-1], Y) = \text{Ext}_D^1(\tau X, Y) \cong D \text{Hom}_D(Y, \tau^2X) \cong D \text{Hom}_D(\tau^{-2}Y, X)$. If $\text{Hom}_D(X, Y) \neq 0$ and $\text{Hom}_D(\tau^{-2}Y, X) \neq 0$ then it is clear that $X$ and $Y$ lie on a cycle. \hfill \Box

Proposition 1.6. The indecomposable objects in $C$ are precisely those of the form $\widetilde{X}$ for $X$ an object in $S$.

Proof. It follows from Proposition 1.2 and its proof that the objects $\widetilde{X}$ for $X$ an object in $S$ are indecomposable objects in $C$. Using the definition of morphisms in $C$ it is easy to see, using Proposition 1.6(a), that if $X, Y \in S$ are such that $\widetilde{X} \cong \widetilde{Y}$ in $C$ then $X$ and $Y$ are already isomorphic in $D$. \hfill \Box

Proposition 1.7. (a) Let $X$ and $Y$ be in $D = D^b(H)$ for a hereditary $k$-algebra $H$. Then we have

$$\text{Ext}_D^1(Y, X) \cong D \text{Ext}_D^1(FX, Y).$$

(b) Let $\widetilde{X}$ and $\widetilde{Y}$ be in $C = D/F$. Then $\text{Ext}_C^1(\widetilde{X}, \widetilde{Y}) \cong \text{Ext}_C^1(\widetilde{Y}, \widetilde{X}).$

(c) Let $X, Y$ be indecomposable $kQ$-modules. Then

$$\text{Ext}_C^1(\widetilde{X}, \widetilde{Y}) \cong \text{Ext}_{kQ}^1(X, Y) \prod \text{Ext}_{kQ}^1(Y, X).$$

(d) If $X, Y$ are $kQ$-modules and $X$ is projective then

$$\text{Hom}_C(\widetilde{X}, \widetilde{Y}) \cong \text{Hom}_{kQ}(X, Y).$$

Proof. (a) We have

$$\text{Ext}_D^1(Y, X) \cong D \text{Hom}_D(\tau^{-1}X, Y) \cong D \text{Ext}_D^1(\tau^{-1}X[1], Y) \cong D \text{Ext}_D^1(FX, Y).$$

(b) follows directly from (a).

(c) We note that, by part (a), $D \text{Ext}_D^1(FX, Y) \cong \text{Ext}_D^1(Y, X) \cong \text{Ext}_{kQ}^1(Y, X).$ Suppose that $i \neq 0, 1$. Then

$$\text{Ext}_D^i(F^iX, Y) \cong \text{Hom}_D(F^iX, Y[1]) \cong \text{Hom}_D(F^{i-1}X, \tau^{-1}Y) \cong \text{Hom}_D(F^iX, \tau^{-1}Y).$$

The result then follows from Proposition 1.3(a), noting that $\tau^{-1}X$ is an object in $S$.

(d) If $X$ is projective, then

$$D \text{Hom}_D(F^{-1}X, Y) = D \text{Hom}_D(\tau X[-1], Y) \cong D \text{Hom}_D(\tau X, Y[1]) \cong \text{Ext}_D^1(\tau X, Y).$$

But $\tau X \cong I[-1]$ for some injective module $I$, so

$$D \text{Hom}_D(F^{-1}X, Y) \cong \text{Ext}_D^1(I[-1], Y) \cong \text{Ext}_D(I, Y[1]) \cong \text{Ext}^2(I, Y) = 0.$$

The claim now follows from Proposition 1.3(a). \hfill \Box
2. Configurations and Tilting Sets

It has been shown in [MRZ] that there is an interesting connection between cluster algebras and tilting theory for hereditary algebras. Motivated by this, we start in this section our investigations of tilting theory in cluster categories.

We start by recalling that (combinatorial) Hom-configurations have been investigated for the stable translation quivers $\Delta$ where $\Delta$ is a simply-laced Dynkin diagram, in connection with the classification of the selfinjective algebras of finite representation type [Rie1]. Here a subset $\mathcal{T}$ of the vertices in $\Delta$ is a Hom-configuration if

(i) $\text{Hom}_{k(\Delta)}(X,Y) = 0$ for all $X \neq Y$ in $\mathcal{T}$, and 
(ii) for any vertex $Z$ in $\Delta$ there is some $X \in \mathcal{T}$ such that $\text{Hom}_{k(\Delta)}(Z,X) \neq 0$.

Of course, this can be formulated for the category $D^b(H)$ when $\Delta$ is the underlying graph of the quiver of $H$. Hom-configurations for factors of $\Delta$ are defined in the same way.

We here formulate analogous conditions using $\text{Ext}^1$ instead of $\text{Hom}$, in the more general setting of the categories $\mathcal{D} = D^b(H)$ or $\mathcal{D}/G = D^b(H)/G$ for an arbitrary finite dimensional hereditary algebra $H$. We say that a subset $\mathcal{T}$ of non-isomorphic indecomposable objects in $\mathcal{D}$ or $\mathcal{D}/G$ is an Ext-configuration if

(E1) $\text{Ext}^1(X,Y) = 0$ for all $X$ and $Y$ in $\mathcal{T}$, and 
(E2) for any indecomposable $Z \not\in \mathcal{T}$ there is some $X \in \mathcal{T}$ such that $\text{Ext}^1(X,Z) \neq 0$.

Note that in (E2) it is clearly necessary to assume that $Z \not\in \mathcal{T}$.

When we have a Hom-configuration $\mathcal{T}$ for $\Delta$, with $\Delta$ Dynkin, it is known that $\mathcal{T}$ is stable under the action of $\tau^{m_\Delta}$. Here $m = m_\Delta$ is the smallest integer such that in $k(\Delta)$, the composition of the maps in a path of length greater than or equal to $m$, is zero. Here $m_{A_n} = n$, $m_{D_n} = 2n - 3$, $m_{E_6} = 11$, $m_{E_7} = 17$ and $m_{E_8} = 29$ [BLR], in each case $m_\Delta = h_\Delta - 1$, where $h_\Delta$ is the Coxeter number of $\Delta$. Further, a fundamental domain for the action of $\tau^{m_\Delta}$ has exactly $n$ objects from $\mathcal{T}$, where $n$ is the number of vertices of $\Delta$, and hence the number of non-isomorphic simple $H$-modules.

The corresponding role for Ext-configurations is played by the functor $F = \tau^{-1}[1]$ on $D^b(H)$, and this is another reason for the importance of this functor.

**Proposition 2.1.** Let $\mathcal{T}$ be an Ext-configuration in $\mathcal{D} = D^b(H)$, and let $M$ be in $\text{ind} \mathcal{D}$. Then $M$ is in $\mathcal{T}$ if and only if $FM$ is in $\mathcal{T}$.

**Proof.** Assume that $M$ is in $\mathcal{T}$. It suffices to show that $FM$ and $F^{-1}M$ are in $\mathcal{T}$. Suppose first that $F^{-1}M \not\in \mathcal{T}$. Then by (E2) there is some $X$ in $\mathcal{T}$ such that $\text{Ext}^1_\mathcal{D}(X,F^{-1}M) \neq 0$, so $\text{Ext}^1_\mathcal{D}(FX,M) \neq 0$. Then $\text{Ext}^1_\mathcal{D}(M,X) \neq 0$ by Proposition 1.7 which gives a contradiction to (E1) since $M$ and $X$ are in $\mathcal{T}$. Hence we have $F^{-1}M \in \mathcal{T}$.

Suppose next that $FM \not\in \mathcal{T}$. Then by (E2) there is an $X$ in $\mathcal{T}$ such that $\text{Ext}^1_\mathcal{D}(X,FM) \neq 0$. Since $X$ is in $\mathcal{T}$ it follows that $F^{-1}X \in \mathcal{T}$ by the first part of the proof. Then $\text{Ext}^1_\mathcal{D}(F^{-1}X,M) \simeq \text{Ext}^1_\mathcal{D}(X,FM) \neq 0$, which contradicts (E1), since $F^{-1}X$ and $M$ are both in $\mathcal{T}$. \qed

There is a connection between Ext-configurations in $\mathcal{D}$ and in $\mathcal{D}/G$, with $G$ satisfying (g1) and (g2), which is especially nice for $G = F$.

**Proposition 2.2.** (a) Suppose that $\tilde{\mathcal{T}}$ is an Ext-configuration in the factor category $\tilde{\mathcal{D}} = D^b(H)/G$. Then $\mathcal{T} = \{X \in D^b(H) \mid \tilde{X} \in \tilde{\mathcal{T}}\}$ is an Ext-configuration in $\mathcal{D}$. 

(b) Let \( \mathcal{T} \) be an Ext-configuration in \( \mathcal{D} \). Then \( \overline{\mathcal{T}} = \{ \overline{X} \mid X \in \mathcal{T} \} \) is an Ext-configuration in \( \mathcal{C} = D^b(H)/F \).

Proof. (a) Let \( X \) and \( Y \) be in \( \mathcal{C} \). Then \( \overline{X} \) and \( \overline{Y} \) in \( \overline{\mathcal{T}} \), so \( \text{Ext}_1^D(\overline{X}, \overline{Y}) = 0 \). Then \( \text{Ext}_1^D(X, Y) = 0 \), so (E1) holds.

Let \( Z \in \text{ind} \mathcal{D} \), such that \( Z \) is not in \( \mathcal{T} \). Then \( \overline{Z} \) is indecomposable in \( \overline{\mathcal{D}} \), with \( \overline{Z} \not\in \overline{\mathcal{T}} \). So by (E2) there is an \( X \in \text{ind} \mathcal{D} \) with \( \overline{X} \in \overline{\mathcal{T}} \) such that \( \text{Ext}_1^D(\overline{X}, \overline{Z}) \neq 0 \) in the factor category. Then \( \text{Ext}_1^D(G^n(X), Z) \neq 0 \) for some \( n \). But \( G^n(X) \) lies in \( \mathcal{T} \), since \( G^n(X) = \overline{X} \), so \( \mathcal{T} \) satisfies (E2). Hence \( \mathcal{T} \) is an Ext-configuration in \( \mathcal{D} \).

(b) Let \( X, Y \) be in \( \mathcal{T} \), so that \( \overline{X}, \overline{Y} \) are in \( \overline{\mathcal{T}} \). Suppose for a contradiction that \( \text{Ext}_1^C(\overline{X}, \overline{Y}) \neq 0 \). Then there is some integer \( n \) such that \( \text{Ext}_1^C(F^n(X), Y) \neq 0 \). Since \( F^n(X) \in \mathcal{T} \) by Proposition 2.4, we have a contradiction to (E1) for \( \mathcal{T} \). Hence \( \overline{\mathcal{T}} \) also satisfies (E1).

Now suppose that \( Y \in \text{ind} \mathcal{D} \) is such that \( \overline{Y} \not\in \overline{\mathcal{T}} \). Then \( \overline{Y} \not\in \overline{\mathcal{T}} \), so there is an \( X \in \mathcal{T} \) such that \( \text{Ext}_1^D(X, Y) \neq 0 \), by (E2) for \( \mathcal{T} \). Then \( \text{Ext}_1^C(\overline{X}, \overline{Y}) \neq 0 \). Since \( \overline{X} \) is in \( \overline{\mathcal{T}} \), it follows that \( \overline{\mathcal{T}} \) satisfies (E2). Therefore \( \overline{\mathcal{T}} \) is an Ext-configuration in \( \mathcal{C} \).

The concept of Ext-configurations is closely related to tilting theory for hereditary algebras. Recall that for a hereditary algebra \( H \), an \( H \)-module \( T \) is said to be a tilting module if

(a) \( \text{Ext}_1^H(T, T) = 0 \), that is \( T \) is exceptional, and there is an exact sequence \( 0 \rightarrow H \rightarrow T_0 \rightarrow T_1 \rightarrow 0 \) with \( T_0 \) and \( T_1 \) in add \( T \) (see [HR]).

There are some useful equivalent characterisations [Bo1]:

(b) \( T \) is exceptional and has \( n \) non-isomorphic indecomposable direct summands (possibly with multiplicities), where \( n \) is the number of non-isomorphic simple modules, or

(c) \( T \) is exceptional and has a maximal number of non-isomorphic indecomposable direct summands.

A tilting module is said to be basic if all of its direct summands are non-isomorphic.

Motivated by this we say that in the categories \( D^b(H) \) or \( D^b(H)/G \) a set of non-isomorphic indecomposable objects \( T \) is a tilting set if it is an exceptional set, that is \( \text{Ext}_1^D(T, T') = 0 \) for all \( T, T' \) in \( \mathcal{T} \), and it is maximal with respect to this property. For \( D^b(H) \) there is already the concept of tilting complexes, which is quite different, since there the vanishing of \( \text{Ext}_1^D(T, T') \) for \( i \neq 0 \) is required. For the case \( \mathcal{C} = D^b(H)/F \) we say that \( T \) in \( \mathcal{C} \) is a tilting object if \( \text{Ext}_1^C(T, T) = 0 \) and \( T \) has a maximal number of non-isomorphic direct summands. We note that an object in \( \mathcal{C} \) is a basic tilting object if and only if it is the direct sum of all objects in a tilting set \( T \). We shall later see that all tilting sets in \( \mathcal{C} \) are finite, so that there will always be a corresponding basic tilting object.

We now discuss the connection between tilting sets, tilting objects and Ext-configurations.

**Proposition 2.3.** Let \( \overline{\mathcal{T}} \) be a set of non-isomorphic objects in \( \text{ind} \mathcal{C} \). Then \( \overline{\mathcal{T}} \) is a tilting set if and only if it is an Ext-configuration.

**Proof.** Suppose that \( \overline{\mathcal{T}} \) is a tilting set in \( \mathcal{C} \). Then \( \overline{\mathcal{T}} \) satisfies (E1) by definition. Let \( M \in \text{ind} \mathcal{C} \) such that \( M \not\in \overline{\mathcal{T}} \). If \( \text{Ext}_1^C(X, M) = 0 \) for all \( X \in \overline{\mathcal{T}} \), then \( \text{Ext}_1^C(M, X) = 0 \) for all \( X \in \overline{\mathcal{T}} \) by Proposition 1.7. Hence \( \overline{\mathcal{T}} \cup \{ M \} \) is exceptional, contradicting the maximality of \( \overline{\mathcal{T}} \). Hence there is some \( X \in \overline{\mathcal{T}} \) such that \( \text{Ext}_1^C(X, M) \neq 0 \), so that (E2) holds, so \( \overline{\mathcal{T}} \) is an Ext-configuration in \( \mathcal{C} \).
Next suppose \( \mathcal{T} \) is an Ext-configuration in \( \mathcal{C} \). Then \( \mathcal{T} \) is exceptional. By (E2), for all \( M \notin \mathcal{T} \) there is some \( X \in \mathcal{T} \) such that \( \text{Ext}^1_{\mathcal{D}}(X, M) \neq 0 \). It follows that \( \mathcal{T} \) is maximal exceptional, and therefore a tilting set.

Note that in \( \mathcal{D} = D^b(H) \) there are tilting sets which are not Ext-configurations. The problem is that \( \text{Ext}^1_{\mathcal{D}}(, \, ) \) is not symmetric.

**Example.** Suppose that \( H \) is the path algebra of a quiver of type \( A_3 \). See Figure 2 for the AR-quiver \( \Gamma(D) \), indicating vertices which lie in \( \mathcal{T} \) by filled-in circles, and those not in \( \mathcal{T} \) by empty circles. The arrows are omitted. It is easy to check that \( \text{Ext}^1_{\mathcal{D}}(X, Y) = 0 \) for all \( X, Y \) in \( \mathcal{T} \), and that \( \mathcal{T} \) is maximal with this property, since for all \( M \notin \mathcal{T} \), there is \( X \in \mathcal{T} \) such that \( \text{Ext}^1_{\mathcal{D}}(X, M) \neq 0 \) or \( \text{Ext}^1_{\mathcal{D}}(M, X) \neq 0 \). In fact for all \( M \notin \mathcal{T} \), there is \( X \in \mathcal{T} \) for which \( \text{Ext}^1_{\mathcal{D}}(X, M) \neq 0 \), except for the module \( N \) corresponding to the encircled vertex. We note that \( \tau N \in \mathcal{T} \) and \( \text{Ext}^1_{\mathcal{D}}(N, \tau N) \neq 0 \). So \( \mathcal{T} \) is a tilting set in \( \mathcal{D} \). We note that \( \mathcal{T} \) is not an Ext-configuration, since \( \text{Ext}^1_{\mathcal{D}}(X, N) = 0 \) for all \( X \in \mathcal{T} \), although \( N \notin \mathcal{T} \). Note also that this subset is not \( F \)-invariant, so could not be an Ext-configuration by Proposition 2.1.

![Figure 2. A tilting set in \( \mathcal{D} \) which is not an Ext-configuration](image)

We shall see in Section 3 that any tilting set in \( \mathcal{C} = D^b(H)/F \) is induced by a basic tilting module over some hereditary algebra derived equivalent to \( H \). Hence by Proposition 2.4 any Ext-configuration in \( \mathcal{C} \) is induced by such a basic tilting module. This gives another analogy with Hom-configurations, since it is known that any Hom-configuration on \( Z \Delta \) for a Dynkin diagram \( \Delta \), is induced by a basic tilting \( H \)-module for a hereditary algebra \( H \) whose quiver has underlying graph \( \Delta \).

Let \( \Delta \) be a simply-laced Dynkin diagram, and denote by \( \Pi(\Delta) \) the preprojective algebra of type \( \Delta \). Then it is known that \( \Pi(\Delta) \) has finite representation type if and only if \( \Delta \) is of type \( A_1 \), \( A_2 \), \( A_3 \) or \( A_4 \) (see [DR]). In type \( A_1 \), the stable module category of \( \Pi(\Delta) \) has only one indecomposable (simple) object. In types \( A_2 \), \( A_3 \) and \( A_4 \), the stable module category of \( \Pi(\Delta) \) can be seen to coincide with the cluster category of type \( A_1 \), \( A_3 \) and \( D_6 \) respectively.

Let \( n \) be the number of non-isomorphic simple \( H \)-modules, and let \( t \) be the number of non-isomorphic indecomposable \( H \)-modules for a hereditary algebra of finite representation type. Then we have seen that a fundamental domain for the action of \( F \) on \( D^b(H) \) has \( t + n \) indecomposable objects, and we have mentioned that there are \( n \) members of an Ext-configuration. For comparison, a fundamental domain for the action of \( \tau^{m \Delta} \) is known to have \( 2t - n \) indecomposable objects, with \( n \) members of a Hom-configuration. So we see that in general “more space” is needed to have a Hom-configuration. But in small cases it may be the same, as the following example shows.

**Example.** Let \( H \) be of type \( A_n \). Then \( t = \frac{n(n+1)}{2} \), so that we have \( \frac{n(n+1)}{2} + n = \frac{n^2 + 3n}{2} \) members of a fundamental domain for \( F \) and \( n(n+1) - n = n^2 \) for \( \tau^{m \Delta} \). We see that for \( n = 3 \), we get 9 in both cases. In this case the preprojective algebra of \( H \) has 9 indecomposable nonprojective modules and induces a Hom-configuration on \( Z A_3 \).
3. Relationship to tilting modules

In this section we show basic tilting modules in mod $H$ induce tilting objects in $\mathcal{C} = D^b(H)/F$ for a hereditary algebra $H$, and that in fact all the basic tilting objects in $\mathcal{C}$ can be obtained from basic tilting modules over hereditary algebras derived equivalent to $H$. This allows us to deduce additional information on the basic tilting objects in $\mathcal{C}$. A basic exceptional object in $\mathcal{C}$ can be extended to a basic tilting object, and the number of indecomposable direct summands in a basic tilting object is the number $n$ of non-isomorphic simple $H$-modules. In particular a basic exceptional object in $\mathcal{C}$ with $n$ non-isomorphic indecomposable direct summands is a basic tilting object in $\mathcal{C}$.

We start with the following immediate relationship between exceptional objects in mod $H$ and in $\mathcal{C}$.

**Lemma 3.1.** Let $T$ be an $H$-module. Then $T$ is exceptional if and only if $T$ is an exceptional object in $\mathcal{C}$.

**Proof.** This follows directly from Proposition 1.7(c). □

We use this to show the following.

**Proposition 3.2.** Let $H$ be a hereditary algebra with $n$ non-isomorphic simple modules, and let $T$ be a basic exceptional object in $\mathcal{C}$. Then $T$ can be extended to a basic tilting object.

**Proof.** We claim that any basic exceptional object $T'$ in $\mathcal{C}$ has at most $2n$ indecomposable summands. Let $T_1, \ldots, T_r, T_{r+1}, \ldots, T_t$ be indecomposable objects in mod $H \vee H[1]$ inducing $T'$. If no $T_i$ is a summand of $H[1]$, then $T_1 \coprod \cdots \coprod T_r$ is a basic exceptional $H$-module, so that $r \leq n$, and hence $t \leq 2n$. In particular any basic exceptional object having $T$ as a direct summand has at most $2n$ indecomposable direct summands, and hence $T$ can be extended to a maximal basic exceptional object in $\mathcal{C}$, which is then by definition a basic tilting object. □

By Lemma 3.1, a basic tilting $H$-module gives rise to a basic exceptional object in $\mathcal{C}$ (as indecomposable $kQ$-modules are isomorphic as modules if and only if they are isomorphic in $\mathcal{C}$). We shall show that this is in fact a basic tilting object, and that any basic tilting object in $\mathcal{C}$ can be obtained this way.

**Theorem 3.3.** (a) Let $T$ be a basic tilting object in $\mathcal{C} = D^b(H)/F$, where $H$ is a hereditary algebra with $n$ simple modules.

(i) $T$ is induced by a basic tilting module over a hereditary algebra $H'$, derived equivalent to $H$.

(ii) $T$ has $n$ indecomposable direct summands.

(b) Any basic tilting module over a hereditary algebra $H$ induces a basic tilting object for $\mathcal{C} = D^b(H)/F$.

**Proof.** (a)(i) Let $T$ be a basic tilting object in $\mathcal{C} = D^b(H)/F$. Let $T_1, \ldots, T_r$ be indecomposable objects in mod $H \vee H[1]$ inducing $T$. If no $T_i$ is a summand of $H[1]$, then $T_1 \coprod \cdots \coprod T_r$ is a basic exceptional $H$-module which we claim is a basic tilting module. If not, we get a basic tilting module by adding a nonzero module as summand. But then this will give rise to a basic exceptional object in $\mathcal{C}$ properly containing $T$ as a direct summand, which is a contradiction to $T$ being a basic tilting object in $\mathcal{C}$.

If no $T_i$ is projective, we have

$$\{T_1, \ldots, T_r\} \subset \tau_D^{-1}(\text{mod } H)$$
and then $T_1 \coprod \cdots \coprod T_r$ is a basic tilting module over a hereditary algebra derived equivalent to $H$ (in fact isomorphic to $H$, but with a different embedding into $D^b(H)$). Assume now that some $T_i$ is projective. Let first $H$ be of infinite representation type. We assume that there are some $T_j$ which are summands of $H[1]$ (otherwise we are done, by the above argument). If $T$ has no injective direct summands, then $\tau_c^{-1}T$ can be represented by a module in $\text{mod}
olimits H$. If $T$ has an injective direct summand (such that $\tau_c^{-1}T$ has a summand in $H[1]$), we can apply $\tau_c^{-1}$ again. It is clear that there is a $t$ such that $\tau_c^{-1}T$ can be represented by a module in $\text{mod}
olimits H$. Hence, $T$ is a module over a hereditary algebra derived equivalent to $H$, and we proceed as above.

Let now $H$ be of finite representation type, and we use the same notation as above, with $T_1, \ldots, T_r$ in $\text{mod}
olimits H \vee H[1]$. We claim that for any simple projective module $S$ not in $\text{add} T$, there is a path to some $T_i$. Since $T$ is a basic tilting object, we have $\text{Ext}^1_T(T, S) \neq 0$, and hence $\text{Hom}_C(S, \tau_cT) \neq 0$. Since $\text{Hom}_D(S, F(\tau_D T)) = \text{Hom}_D(S, T[1]) = 0$, we must have $\text{Hom}_D(S, \tau_D T) \neq 0$ (using Proposition 1.3(a)), and consequently we have a path of the desired type. Denote by $\alpha(H)$ the sum of the lengths of all paths (where paths through the same sequence of vertices are counted only once) from a simple projective $H$-module which is not in $\text{add} T$, to some $T_i$. By possibly replacing $H$ by a derived equivalent hereditary algebra, we can assume that $\alpha(H)$ is smallest possible, when all $T_i$ are in $\text{mod}
olimits H \vee H[1]$. If $\alpha(H) > 0$, there is some simple projective $H$-module $S$ not in $\text{add} T$. By performing an APR-tilt (see [APR]) using the basic tilting module $M = \tau^{-1}S \coprod P$, where $H = S \coprod P$, to get $H' = \text{End}_H(M)^{\text{op}}$, it is easy to see that $\alpha(H') < \alpha(H)$, and that $H'$ satisfies the desired properties. This contradiction implies that $\alpha(H) = 0$, so that all simple projective $H$-modules are in $\text{add} T$.

We next want to show that no $T_i$ is a summand of $\tau_D^{-1}H$. Assume to the contrary that there is an indecomposable projective $H$-module $P$ with $\tau_D^{-1}P$ in $\text{add} T$. There is a simple projective $H$-module $S$ with $\text{Hom}_H(S, P) \neq 0$, and as we have seen, it is in $\text{add} T$. Since $\text{Ext}^1_T(\tau^{-1}P, S) \simeq \text{Hom}_H(S, P)$, we have a contradiction to $T$ being exceptional. Hence no $T_i$ is a summand of $\tau_D^{-1}H$.

Choose $H'$ derived equivalent to $H$ such that $\tau_D^{-2}(\text{mod}
olimits H \vee H[1]) = \text{mod}
olimits H' \vee H'[1]$. Since no $T_i$ is a summand of $\tau_D^{-1}H$, no $T_i$ is a summand of $H'[1]$ (now regarding the $T_i$ as objects in $\text{mod}
olimits H' \vee H'[1]$; see Proposition 1.3). So $T$ is a basic exceptional $H'$-module which has to be a basic tilting module.

(a)(ii) This is clearly a consequence of part (i).

(b) Let $T$ be a basic exceptional object in $\mathcal{C}$ induced by a basic tilting $H$-module. Then $T$ has $n$ indecomposable direct summands, and can be extended to a basic tilting object by Proposition 3.2. But any basic tilting object has $n$ indecomposable direct summands, and consequently $T$ is a basic tilting object in $\mathcal{C}$.

We note that the basic tilting modules of $kQ$ are in bijection with the Hom-configurations of $D$. The above Theorem indicates a link between tilting sets in $\mathcal{C}$ and basic tilting modules, which, in the light of Propositions 2.2 and 2.3 gives a link between Ext-configurations in $D$ and basic tilting modules. It would be interesting to find a direct link between the Hom-configurations and the Ext-configurations of $D$.

The previous investigation holds more generally in the setting of a hereditary abelian category $\mathcal{H}$ with finite dimensional Hom-spaces and Ext-spaces and with a tilting object $T$, as introduced and investigated in [HRS]. We still have Serre duality for $D^b(\mathcal{H})$ and hence almost split triangles, (see [HRS], [RV]) and Keller’s theorem on $\mathcal{C}_H = D^b(\mathcal{H})/F$ being triangulated is proved in this generality [K]. It is also known in this setting that a basic object $T$ in $\mathcal{H}$ is a tilting object if and only if
Ext^1_H(T, T) = 0 and the number of indecomposable direct summands of T is equal
to the rank of the Grothendieck-group of H. Furthermore, any exceptional object
can be extended to a tilting object, see [HU1]. Using this, the previous results carry
over to this setting.

When H is connected and not equivalent to some mod H for a hereditary algebra
H, it is known that H has no non-zero projective or injective objects, see [HU2].

In this case it is clear that ind H is a fundamental domain for F under the action
of F. For if X is in ind H, then F^i X is in ind H[i], so that no other object in the
F-orbit of X is in ind H. And given any Y in ind D, we have Y[i] ∈ H for some i,
and so F^i Y = τ^{-i} Y[i] is in H since H is closed under positive and negative powers
of τ. We then get the following.

**Proposition 3.4.** Let H be a hereditary abelian k-category over a field k, with finite
dimensional Hom-spaces and Ext^1-spaces. Assume H has no nonzero projective or
injective objects, and assume that H has a tilting object. Then there is a natural
1–1 correspondence between the exceptional objects in H and in C_H = D^b(H)/F.
The correspondence preserves tilting objects.

As has previously been done for mod H and other hereditary categories H with
tilting objects (see [HU2]), one can associate to C a tilting graph whose vertices
are the basic tilting objects, and where there is an edge between two vertices if
the corresponding tilting objects have all but one indecomposable summands in
common. It is known that for mod H the graph is not always connected, but this
is the case for the hereditary abelian Ext-finite k-categories with tilting objects
derived equivalent, but not equivalent, to mod H [HU2]. Using this last result, we
obtain the following.

**Proposition 3.5.** For an indecomposable hereditary k-algebra H, the tilting graph
of C = C_H defined above is connected.

**Proof.** If H is given by a Dynkin diagram, the tilting graph for mod H is connected,
as pointed out in [HU2], and hence the same is true for the tilting graph of C.

If H is of infinite representation type, it is known that there is some indecomposable
hereditary abelian k-category H with tilting objects, finite dimensional
Hom-spaces and Ext-spaces and no nonzero projective or injective objects, with
D^b(mod H) equivalent to D^b(H) (see e.g. [HU2]). Consequently C_H is equivalent
to C_H. It follows from Proposition 3.4 that the tilting graph for H and C_H are
isomorphic. Since it is proved in [HU2] that the tilting graph of H is connected,
our result follows. □

4. Connections with Cluster Algebras

In this section, we assume that H is the path algebra of a simply-laced quiver
of Dynkin type, with underlying graph Δ, and that k is algebraically closed. We
denote by A = A(Δ) the corresponding cluster algebra [FZ2]. Let Φ denote the set
of roots of the corresponding Lie algebra, and let Φ ≥−1 denote the set of almost
positive roots, i.e. the positive roots together with the negatives of the simple roots.
The cluster variables of A are in 1–1 correspondence with the elements of Φ ≥−1.
Fomin and Zelevinsky associate a nonnegative integer (α||β), known as the
compatibility degree, to each pair α, β of almost positive roots. This is defined in
the following way. Let s_i be the Coxeter generator of the Weyl group of Φ corresponding
to i, and let σ_i be the permutation of Φ ≥−1 defined as follows:

σ_i(α) = \begin{cases} 
α & \text{if } α = -α_j, \ j \neq i \\
\sigma_i(α) & \text{otherwise}. 
\end{cases}
Let $I = I^+ \sqcup I^-$ be a partition of the set of vertices $I$ of $\Delta$ into completely disconnected subsets and define:

$$\tau_{\pm} = \prod_{i \in I^\pm} \sigma_i.$$ 

Then (||) is defined by setting $(-\alpha_i || \beta)$ to be the coefficient of $\alpha_i$ in $\beta$, and by specifying that it is $\tau_{\pm}$-invariant.

In [MRZ], it was shown that the combinatorics of $A$ could be obtained from the category of decorated representations of a quiver $Q$ with underlying graph $\Delta$. In particular, this allowed the generalised associahedra (Stasheff polytopes) of [CFZ] to be constructed directly from the representation theory of $Q$, and gave, for the first time, a uniform formula for the number of basic tilting modules over $kQ$ in terms of the degrees of the corresponding Weyl group. The compatibility degree, key to the construction of the associahedron, was interpreted as the dimension of a certain bifunctor from the decorated category to the category of finite-dimensional vector spaces, in the case where the quiver was alternating. This bifunctor can be regarded as a symmetrised version of $\text{Ext}^1$.

In this section, we will show that such a construction can be made in a more symmetric way, via the category $\mathcal{C} = D^b(H)/F$. This approach has the advantage that the category $\mathcal{C}$ is independent of the orientation of the quiver considered. We show that, when the indecomposable objects of $\mathcal{C}$ are labelled appropriately with decorated representations (in a way dependent on the orientation of the quiver) the dimension of an $\text{Ext}^1$-group coincides with the dimension of the symmetrised bifunctor mentioned above. Thus, when $\mathcal{C}$ is labelled in a way corresponding to the alternating quiver, the combinatorics of the corresponding cluster algebra is recovered in terms of $\text{Ext}^1$-groups of $\mathcal{C}$. In particular, we will show that the clusters are in 1–1 correspondence with the basic tilting objects in $\mathcal{C}$.

We first of all show that the $\text{Ext}^1$-groups in $\mathcal{C}$ coincide with the symmetrised $\text{Ext}^1$-groups used for the decorated representations in [MRZ]. Recall that in [MRZ] the quiver $Q$, with vertices $Q_0$ and arrows $Q_1$, is replaced by a “decorated” quiver $\tilde{Q}$, with an extra copy $Q_0^- = \{i_- : i \in Q_0\}$ of the vertices of $Q$ (with no arrows incident with the new copy). A module $M$ over $k\tilde{Q}$ can be written in the form $M^+ \coprod V$, where $M^+ = \coprod_{i \in Q_0^+} M_i^+$ is a $kQ$-module, and $V = \coprod_{i \in Q_0^-} V_i$ is a $Q_0$-graded vector space over $k$. Its signed dimension vector, $\text{sdim}(M)$ is the element of the root lattice of the Lie algebra of type $\Delta$ given by

$$\text{sdim}(M) = \sum_{i \in Q_0^+} \dim(M_i^+)\alpha_i - \sum_{i \in Q_0^-} \dim(V_i)\alpha_i,$$

where $\alpha_1, \alpha_2, \ldots, \alpha_n$ are the simple roots. By Gabriel’s Theorem, the indecomposable objects of $kQ$-mod are parametrised, via $\text{sdim}$, by the almost positive roots, $\Phi_{\geq -1}$, of the corresponding Lie algebra, i.e. the positive roots together with the negative simple roots. The positive roots correspond to the indecomposable $kQ$-modules, and the the negative simple roots correspond to the simple modules associated with the new vertices. We denote the simple module corresponding to the vertex $i_-$ by $S_i^-$. Let $M = M^+ \coprod V$ and $N = N^+ \coprod W$ be two $kQ$-modules. The symmetrised $\text{Ext}^1$-group for this pair of modules is defined to be:

$$E_{kQ}(M, N) := \text{Ext}_{kQ}^1(M^+, N^+) \coprod \text{Ext}_{kQ}^1(N^+, M^+) \coprod \text{Hom}_{Q_0}^1(M^+, W) \coprod \text{Hom}_{Q_0}^1(V, N^+),$$

where $\text{Hom}_{Q_0}^1$ denotes homomorphisms of $Q_0$-graded vector spaces.
We define a map $\psi_Q$ from $\text{ind} \mathcal{C}$ to the set of isomorphism classes of indecomposable $kQ$-modules as follows. Let $\bar{X} \in \text{ind} \mathcal{C}$. We can assume that one of the following cases holds:

1. $X$ is an indecomposable $kQ$-module $M^+$.
2. $X = P_i[1]$ where $P_i$ is the indecomposable projective $kQ$-module corresponding to vertex $i \in Q_0$.

We define $\psi_Q(\bar{X})$ to be $M^+$ in Case (1), and to be $S_i^-$ in Case (2).

The following is clear:

**Proposition 4.1.** The map $\psi_Q$ is a bijection between $\text{ind} \mathcal{C}$ and the set of isomorphism classes of indecomposable $kQ$-modules (i.e. indecomposable decorated representations). It follows that $\gamma_Q := \text{sdim} \circ \psi_Q$ is a bijection between $\text{ind} \mathcal{C}$ and $\Phi_{\geq -1}$ (and thus induces a bijection between $\text{ind} \mathcal{C}$ and the set of cluster variables).

For $\alpha \in \Phi_{\geq -1}$ we denote by $M_Q(\alpha)$ the element of $\text{ind} \mathcal{C}$ such that $\gamma_Q(M_Q(\alpha)) = \alpha$.

**Proposition 4.2.** Let $X, Y$ be objects of $\mathcal{D}$. Then

$$E_{kQ}(\psi_Q(\bar{X}), \psi_Q(\bar{Y})) \simeq \text{Ext}^1_{kQ}(\bar{X}, \bar{Y}).$$

**Proof.** Without loss of generality, we can assume that $X$ and $Y$ are either indecomposable $kQ$ modules or of the form $P_i[1]$ where $P_i$ is an indecomposable projective $kQ$-module. We first of all consider the case where $X = M^+$ and $Y = N^+$ are both indecomposable $kQ$-modules. Then $E_{kQ}(\psi_Q(\bar{X}), \psi_Q(\bar{Y})) = \text{Ext}^1_{kQ}(M^+, N^+) \bigoplus \text{Ext}^1_{kQ}(N^+, M^+)$ which is isomorphic to $\text{Ext}^1_{kQ}(M^+, \bar{N}^-)$ by Proposition 1.7. Next, suppose that $X = P_i[1]$ and that $Y = N^+$, where $P_i$ is an indecomposable projective and $N^+$ is an indecomposable $kQ$-module. Then

$$E_{kQ}(\psi_Q(\bar{X}), \psi_Q(\bar{Y})) = \text{Hom}_{kQ}(\bar{S}^-_i, N^+)$$

and has dimension given by the multiplicity of $\alpha_i$ in the positive root corresponding to $N^+$. We also have:

$$\text{Ext}^1_{kQ}(\bar{X}, \bar{Y}) \simeq \text{Ext}^1_{kQ}(\bar{P}_i[1], \bar{N}^-) \simeq \text{Ext}^1_{kQ}(\bar{P}_i, \bar{N}^-) \simeq \text{Hom}_{kQ}(\bar{P}_i, \bar{N}^+),$$

the last step by Proposition 1.7. This also has dimension equal to the multiplicity of $\alpha_i$ in the positive root corresponding to $N^+$.

In this situation, we also have $\text{Ext}^1_{kQ}(\bar{Y}, \bar{X}) \simeq \text{Ext}^1_{kQ}(\bar{X}, \bar{Y})$ of the same dimension, and $E_{kQ}(\psi_Q(\bar{Y}), \psi_Q(\bar{X})) = \text{Hom}_{kQ}(\bar{N}^+, \bar{S}^-_i)$ with the same dimension, so the only case left to consider is when $X = P_i[1]$ and $Y = P_j[1]$ where $P_i$ and $P_j$ are indecomposable $kQ$-modules. In this case, $E_{kQ}(\psi_Q(\bar{X}), \psi_Q(\bar{Y})) = 0$, and

$$\text{Ext}^1_{kQ}(\bar{X}, \bar{Y}) = \text{Ext}^1_{kQ}(\bar{P}_i[1], \bar{P}_j[1]) \simeq \text{Ext}^1_{kQ}(\bar{P}_i, \bar{P}_j[1]) = 0$$

by Proposition 1.7. \qed
This proposition shows that \( \mathcal{C} \), which is independent of the orientation of its defining quiver, can be regarded as a “symmetrised” (orientation independent) version of the decorated categories \( k\mathcal{Q}\text{-mod} \), since \( E_{k\mathcal{Q}} \) can be modelled for all orientations \( Q \) of \( \Delta \) by \( \mathcal{C} \), via the labellings \( \psi_Q \).

We therefore have:

**Corollary 4.3.** Let \( \alpha, \beta \in \Phi_{\geq -1} \). Then we have

\[
(\alpha \| \beta)_Q = \dim \text{Ext}^1_{\mathcal{C}}(M_Q(\alpha),M_Q(\beta)),
\]

where \( (\alpha \| \beta)_Q \) denotes the \( Q \)-compatibility degree of \( \alpha \) and \( \beta \) (see [MRZ, Eq.(3.3)]).

We also have the following consequences. Let \( \Delta(\mathcal{C}) \) be the abstract simplicial complex on \( \mathcal{C} \) with simplices given by the exceptional sets in \( \mathcal{C} \), i.e. the subsets of tilting sets. Thus the maximal simplices are the tilting sets.

**Corollary 4.4.** Let \( Q \) be any quiver of type \( \Delta \). Then \( \Delta(\mathcal{C}) \) is isomorphic to the abstract simplicial complex \( \Delta_Q \) of [MRZ, 3.7,4.11].

Corollary 4.4 together with [MRZ, 4.11,4.12] show that the simplicial complex \( \Delta(\Phi) \) of [CFZ, p6] can be obtained in a natural way from the category \( \mathcal{C} \) associated to \( \Phi \).

**Theorem 4.5.** Let \( Q = Q_{\text{alt}} \) be an alternating quiver of type \( \Delta \). Then the map \( \alpha \mapsto M_{Q_{\text{alt}}}(\alpha) \) between \( \Phi_{\geq -1} \) and \( \text{ind}\, \mathcal{C} \) induces a bijection between the following sets:

1. The set of clusters in a cluster algebra of type \( \Delta \).
2. The set of basic tilting objects in \( \mathcal{C} \).

**Proof.** The induced map is given by applying the map \( \alpha \mapsto M_{Q_{\text{alt}}}(\alpha) \) pointwise to a cluster regarded as a subset of \( \Phi_{\geq -1} \). The result follows from Corollary 13 and [MRZ, 4.12]. \( \square \)

**Example.** In Figure 3 we indicate the labelling of \( \text{ind}\, \mathcal{C} \) (via its AR-quiver) from Theorem 4.5 in type \( A_3 \). Objects with the same label are identified. A positive root \( \alpha_i + \alpha_{i+1} + \cdots + \alpha_j \) is denoted by \( i, i+1, \ldots, j \) and a negative root \( -\alpha_i \) is denoted by \( -i \).

We recall that it is known that there is a bijection between the clusters in type \( A_n \) and the vertices of the \( n \)-dimensional associahedron — see [CFZ, 1.4]. In Figure 4 we show the 14 tilting sets in type \( A_3 \), associated to the vertices of the 3-dimensional associahedron via the bijection in Theorem 4.5. The filled-in circles indicate the elements of the tilting set; note that the duplicated vertices of Figure 3 do not appear in these diagrams.

![Figure 3. The labelled AR-quiver of \( \mathcal{C} \) in type \( A_3 \)](image)

**Proposition 4.6.** Given a basic \( k\mathcal{Q}\)-tilting module \( T \), we can write it as a direct sum \( T = \bigsqcup_{\alpha \in S} X_{\alpha} \) where \( S \subset \Phi_+ \) and \( X_{\alpha} \) is the indecomposable \( k\mathcal{Q}\)-module corresponding to \( \alpha \in \Phi_+ \). Let \( \varepsilon(T) := \bigsqcup_{\alpha \in S} M_Q(\alpha) \). Then \( \varepsilon(T) \) is a basic tilting object of \( \mathcal{C} \), and \( \varepsilon \) defines an embedding of the set of basic tilting \( k\mathcal{Q}\)-modules into the set of basic tilting objects of \( \mathcal{C} \).
Figure 4. The 14 tilting sets of $C$ in type $A_3$

Proof. The result follows immediately from Proposition 1.7. □

Let $\Delta_{\text{mod}}(Q)$ denote the complex of basic exceptional $kQ$-modules. This is an abstract simplicial complex on the set of isomorphism classes of indecomposable $kQ$-modules, with the simplices given by the basic exceptional $kQ$-modules. This complex was studied by C. Riedtmann and A. Schofield [RS2], and L. Unger [U2] following a suggestion of C. M. Ringel.

Corollary 4.7. Let $Q$ be any quiver of type $\Delta$. The map $\varepsilon$ induces an embedding of $\Delta_{\text{mod}}(Q)$ into $\Delta(C)$.

Proof. We note that $\varepsilon$ actually defines an embedding of the set of basic exceptional $kQ$-modules into the set of exceptional sets of $C$. □

For the algebra $kQ$, where $Q$ is the quiver given by $A_n$ with linear orientation, the tilting graph of the category of finite-dimensional $kQ$-modules, as discussed in Section 3, can be regarded as the skeleton of a simplicial complex with simplices the faithful basic exceptional modules. This simplicial complex is in fact the Stasheff associahedron of dimension $n - 1$, see [BK].

5. COMPLEMENTS OF ALMOST COMPLETE BASIC TILTING OBJECTS

Let $H$ be a finite dimensional hereditary algebra with $n$ non-isomorphic simple modules. An $H$-module $\overline{T}$ is said to be an almost complete basic tilting module if it is basic exceptional and has $n - 1$ indecomposable direct summands. Then there is automatically an indecomposable module $M$ such that $\overline{T} \coprod M$ is a basic tilting module. Such an indecomposable module is known as a complement to $\overline{T}$. It is known that $\overline{T}$ can be completed to a basic tilting module in at most two different ways [RS1, U1] and it can be done in exactly two ways if and only if $\overline{T}$ is sincere [HU1], that is, each simple module occurs as a composition factor of $\overline{T}$. We investigate the analogous concept for the category $C = D^b(\text{mod} H)/F$, and show that in this context an almost complete basic tilting object has exactly two complements. Hence there is a more regular behaviour in $C$. Certain classes of hereditary categories exhibit a similar behaviour [HU2]. The analogous question has been investigated for arbitrary artin algebras [CHU].
We say that a basic exceptional object \( \mathcal{T} \) in \( \mathcal{C} \) is an almost complete basic tilting object if there is an indecomposable object \( M \) in \( \mathcal{C} \) such that \( \mathcal{T} \amalg M \) is a basic tilting object. Then we have the following main result of this section.

**Theorem 5.1.** Let \( H \) be a finite dimensional hereditary algebra, and \( \mathcal{T} \) an almost complete basic tilting object in \( \mathcal{C} = D^b(H)/F \). Then \( \mathcal{T} \) can be completed to a basic tilting object in \( \mathcal{C} \) in exactly two different ways.

**Proof.** By Theorem 3.3 we can assume that \( \mathcal{T} \) is an \( H \)-module. Since \( \mathcal{T} \) is a basic exceptional \( H \)-module with \( n - 1 \) non-isomorphic direct summands, where \( n \) is the number of non-isomorphic simple \( H \)-modules, \( \mathcal{T} \) is an almost complete basic tilting module over \( H \).

Assume \( \mathcal{T} \) is sincere and let \( M_1 \) and \( M_2 \) be the complements in \( \text{mod} \, H \). Since \( \mathcal{T} \amalg M_1 \) and \( \mathcal{T} \amalg M_2 \) are basic tilting \( H \)-modules, they induce basic tilting objects in \( \mathcal{C} \) by Theorem 3.3. Hence \( M_1 \) and \( M_2 \) are complements to \( \mathcal{T} \) in \( \mathcal{C} \). If another complement \( M_3 \) comes from an \( H \)-module, then \( \mathcal{T} \amalg M_3 \) would be a basic exceptional \( H \)-module by Lemma 5.1 and hence a basic tilting \( H \)-module, which is impossible. Let \( P \) be an indecomposable projective \( H \)-module. Then \( \text{Ext}^1_H(P[1], \mathcal{T}) \simeq \text{Hom}_H(P, \mathcal{T}) = \text{Hom}_H(P, \mathcal{T}) \neq 0 \) (using Proposition 1.7(d)), since \( \mathcal{T} \) is sincere. Therefore \( P[1] \) can not be a complement to \( \mathcal{T} \). Hence we have exactly two complements when \( \mathcal{T} \) is a sincere \( H \)-module.

Assume now that \( \mathcal{T} \) is not sincere as an \( H \)-module, so that there is exactly one indecomposable \( H \)-module which is a complement of \( \mathcal{T} \). It follows as above that there are no more indecomposable \( H \)-modules which induce complements of \( \mathcal{T} \) in \( \mathcal{C} \). Since \( \mathcal{T} \) is not sincere, there is an indecomposable projective \( H \)-module \( Q \) such that \( \text{Hom}_H(Q, \mathcal{T}) = 0 \).

Let \( \Gamma \) be the quiver of \( H \), which we can assume to be a basic algebra, and \( \Gamma' \) the subquiver obtained by removing the vertex \( e \) of \( \Gamma \) corresponding to \( Q \), and all arrows starting or ending at \( e \). So the corresponding path algebra \( k\Gamma' \) is isomorphic to \( H/HeH \). Then \( \mathcal{T} \) is clearly a \( k\Gamma' \)-module, and we obviously have \( \text{Ext}^1_{k\Gamma'}(\mathcal{T}, \mathcal{T}) = 0 \) since \( \text{Ext}^1_{k\Gamma'}(\mathcal{T}, \mathcal{T}) = 0 \). Since \( k\Gamma' \) has \( n - 1 \) vertices, and \( \mathcal{T} \) has \( n - 1 \) non-isomorphic indecomposable summands, \( \mathcal{T} \) is a basic tilting module over \( k\Gamma' \). Therefore \( \mathcal{T} \) is a faithful (and hence sincere) \( k\Gamma' \)-module. In particular \( \text{Hom}_{k\Gamma'}(P, \mathcal{T}) \neq 0 \) for any indecomposable projective \( k\Gamma' \)-module \( P \), so that \( Q \) is the only indecomposable projective \( H \)-module with \( \text{Hom}_H(Q, \mathcal{T}) = 0 \).

If \( P[1] \), with \( P \) an indecomposable projective \( H \)-module, is a complement of \( \mathcal{T} \) in \( \mathcal{C} = D^b(H)/F \), we must have \( \text{Ext}^1_H(P[1], \mathcal{T}) = 0 \), so that \( \text{Hom}_H(P, \mathcal{T}) = 0 \), and hence \( \text{Hom}_H(P, \mathcal{T}) = 0 \). So we must have \( P \simeq Q \); in particular at most one possibility.

Conversely, if \( \text{Hom}_H(Q, \mathcal{T}) = 0 \), we have \( \text{Ext}^1_H(Q[1], \mathcal{T}) = 0 \) and

\[
\text{Ext}^1_H(Q[1], F\mathcal{T}) = \text{Ext}^1_H(Q, \tau^{-1}\mathcal{T}) = \text{Ext}^1_H(I[1], \mathcal{T}) = \text{Ext}^2_H(I, \mathcal{T}) = 0,
\]

where \( I \in \text{mod} \, H \). We also have

\[
\text{Ext}^1_H(Q[1], F^{-1}\mathcal{T}) = \text{Ext}^1_H(Q[1], \tau\mathcal{T}[-1]) = 0.
\]

Furthermore,

\[
\text{Ext}^1_H(\mathcal{T}, Q[1]) = \text{Ext}^2_H(\mathcal{T}, Q) = 0,
\]

and

\[
\text{Ext}^1_H(Q[1], F^{-1}(Q)) = \text{Ext}^1_H(\mathcal{T}, \tau Q[-1]) = \text{Ext}^1_H(I[-2]) = 0,
\]

where \( I \in \text{mod} \, H \). Hence we see that \( \mathcal{T} \amalg Q[1] \) is a basic tilting object in \( \mathcal{C} = D^b(H)/F \), so that \( Q[1] \) is a complement. \( \square \)
6. DESCRIPTION OF COMPLEMENTS VIA APPROXIMATIONS

We shall now see how, starting with a complement of an almost complete basic tilting object, we can construct the other one by using minimal left and right approximations in \( C = D^b(H)/F \). This is possible since \( C \) is a Krull-Schmidt category. We shall also use that \( C \) is in a canonical way a triangulated category, namely the canonical functor \( D \to C \) is a triangle functor.

We recall the definition of minimal left and right approximations, which come from the theory of covariantly and contravariantly finite subcategories [AS]. Suppose that \( \mathcal{E} \) is an additive category, that \( \chi \) is an additive subcategory of \( \mathcal{E} \), and \( E \) is an object of \( \mathcal{E} \). A map \( Y \to E \) with \( Y \) an object of \( \chi \) is called a right \( \chi \)-approximation if the induced map \( \text{Hom}_\mathcal{E}(X,Y) \to \text{Hom}_\mathcal{E}(X,E) \) is an epimorphism for every object \( X \) of \( \chi \). There is the dual notion of a left \( \chi \)-approximation. A map \( f : E \to F \) in an arbitrary category \( \mathcal{E} \) is called right minimal if for every \( g : E \to E \) such that \( fg = f \), the map \( g \) is an isomorphism. Then there is the dual notion of left minimal map. A right (respectively, left) approximation that is also right (respectively, left) minimal is called a minimal right (respectively, left) approximation.

So let as before \( \bar{T} \) be an almost complete basic tilting object in \( C \), and let \( M \) be a complement. Let \( f : B \to M \) be a minimal right add \( \bar{T} \)-approximation of \( M \) in \( C \), and complete this map to a triangle

\[
M^* \xrightarrow{\delta} B \xrightarrow{f} M \to M^*[1]
\]

in \( C \). We show in this section that \( M^* \) is the second complement to \( \bar{T} \). This can be seen as a generalisation of a result of Happel and Unger.

**Proposition 6.1.** [HU] Let \( \bar{T} \) be a sincere almost complete tilting module over a hereditary algebra \( H \). Then there are exactly two non-isomorphic complements \( M^* \) and \( M \) in \( \text{mod} H \), and an exact sequence

\[
0 \to M^* \to B \to M \to 0,
\]

in \( \text{mod} H \), where \( B \to M \) is a minimal right add \( \bar{T} \)-approximation in \( \text{mod} H \).

The exact sequence (4) gives rise to a triangle in \( D \), and thus to a triangle in \( C \).

**Lemma 6.2.** Assume \( \bar{T} \) is an almost complete tilting object in \( C \) induced by a sincere almost complete tilting module in \( \text{mod} H \). Then the triangle (3) in \( C \) is induced by the exact sequence (4).

**Proof.** We need to show that the right add \( \bar{T} \)-approximation \( B \to M \) in \( \text{mod} H \), is also a right add \( \bar{T} \)-approximation in \( C \). View (3) as a triangle in \( D \) and apply \( \text{Hom}_D(F^{-1}\bar{T}, \_ ) \) to it, to obtain an exact sequence

\[
\text{Hom}_D(F^{-1}\bar{T}, B) \to \text{Hom}_D(F^{-1}\bar{T}, M) \to \text{Hom}_D(F^{-1}\bar{T}, M^*[1]),
\]

where \( \text{Hom}_D(F^{-1}\bar{T}, M^*[1]) = \text{Hom}_D(\tau T, M^*[2]) = 0 \). Thus, the claim follows by Proposition 6.3. \( \square \)

To prove that \( M^* \) is a second complement to \( \bar{T} \) we use the following preliminary results.

**Lemma 6.3.** With the above notation, we have \( \text{Ext}^1_C(\bar{T}, M^*) = 0 = \text{Ext}^1_C(M^*, \bar{T}) \).

**Proof.** Applying \( \text{Hom}_C(\bar{T}, \_ ) \) to the triangle \( M^* \to B \to M \to M^*[1] \) we get the exact sequence

\[
\text{Hom}_C(\bar{T}, M^*) \to \text{Hom}_C(\bar{T}, B) \xrightarrow{\text{Hom}_C(\bar{T}, f)} \text{Hom}_C(\bar{T}, M) \to \text{Ext}^1_C(\bar{T}, M^*) \to \text{Ext}^1_C(\bar{T}, B).
\]
Since \( \text{Ext}^1_C(T, B) = 0 \) because \( B \) is in \( \text{add } T \) and \( \text{Ext}^1_C(T, f) = 0 \), and \( \text{Hom}_C(T, f) \) is surjective since \( f: B \rightarrow M \) is a right \( \text{add } T \)-approximation, we get \( \text{Ext}^1_C(T, M^*) = 0 \).

By the symmetry property of \( \text{Ext}^1 \)-approximation, we also get \( \text{Ext}^1_C(M^*, T) = 0 \).

**Lemma 6.4.** The map \( g: M^* \rightarrow B \) is a minimal left \( \text{add } T \)-approximation in \( \mathcal{C} \).

**Proof.** Apply \( \text{Hom}_C( , T) \) to the triangle \( M^* \rightarrow B \rightarrow M \rightarrow M^*[1] \) to get the exact sequence

\[
\text{Hom}_C(B, T) \xrightarrow{\text{Hom}_C(g, T)} \text{Hom}_C(M^*, T) \rightarrow \text{Ext}^1_C(M, T).
\]

Since \( T \bigoplus M \) is a basic tilting object in \( \mathcal{C} \), we have \( \text{Ext}^1_C(M, T) = 0 \), and hence

\[
\text{Hom}_C(g, T): \text{Hom}_C(B, T) \rightarrow \text{Hom}_C(M^*, T)
\]

is surjective. So \( g: M^* \rightarrow B \) is a left \( \text{add } T \)-approximation.

We now show that \( g: M^* \rightarrow B \) is a left minimal map. If it was not, then a summand \( 0 \rightarrow B_1 \) would split off, where \( B_1 \) is a nonzero summand of \( B \). But then \( B_1 \not\geq B_1 \) would be a direct summand of \( f: B \rightarrow M \). Since \( M \) is indecomposable, we would have \( M \simeq B_1 \), contradicting that \( B_1 \) is in \( \text{add } T \), and that \( M \) is a complement of \( T \). Our claim then follows. \( \square \)

**Lemma 6.5.** \( M^* \) is indecomposable.

**Proof.** Assume that \( M^* = U \bigoplus V \) with \( U \) and \( V \) nonzero. Let \( f_1: U \rightarrow B_1 \) and \( f_2: U \rightarrow B_2 \) be minimal left \( \text{add } T \)-approximations, and complete the two maps to triangles

\[
U \rightarrow B_1 \rightarrow X \rightarrow U[1]
\]

and

\[
V \rightarrow B_2 \rightarrow Y \rightarrow V[1].
\]

The direct sum of the triangles is

\[
M^* \rightarrow B \rightarrow M \rightarrow M^*[1],
\]

and so \( M = X \bigoplus Y \). Hence \( X = 0 \) or \( Y = 0 \). If \( X = 0 \), then \( B_1 \rightarrow 0 \) is a direct summand of \( f: B \rightarrow M \), which contradicts \( f \) being right minimal. Similarly \( Y = 0 \) leads to a contradiction. Hence \( M^* \) is indecomposable. \( \square \)

**Lemma 6.6.** \( M^* \) is not in \( \text{add } T \).

**Proof.** If \( M^* \) was in \( \text{add } T \), then \( g: M^* \rightarrow B \) would be an isomorphism, and hence \( M = 0 \), which is a contradiction. \( \square \)

To show that \( T \bigoplus M^* \) is a basic tilting object in \( \mathcal{C} \), it remains to show the following.

**Lemma 6.7.** \( \text{Ext}^1_C(M^*, M^*) = 0 \).

**Proof.** Consider again the triangle

\[
M^* \xrightarrow{g} B \xrightarrow{f} M \rightarrow M^*[1].
\]

Apply \( \text{Hom}_C( , M) \) to get the exact sequence

\[
\text{Hom}_C(B, M) \xrightarrow{\text{Hom}_C(g, M)} \text{Hom}_C(M^*, M) \rightarrow \text{Ext}^1_C(M, M).
\]

Since \( \text{Ext}^1_C(M, M) = 0 \), the map \( \text{Hom}_C(g, M) \) is surjective. Hence any map \( h: M^* \rightarrow M \) factors through \( g: M^* \rightarrow B \). Now apply \( \text{Hom}_C(M^*, ) \) to the triangle to get the exact sequence

\[
\text{Hom}_C(M^*, B) \xrightarrow{\text{Hom}_C(M^*,f)} \text{Hom}_C(M^*, M) \rightarrow \text{Ext}^1_C(M^*, M^*) \rightarrow \text{Ext}^1_C(M^*, B),
\]
where the last term is zero. To show that $\text{Ext}^1_C(M^*, M^*) = 0$ it is therefore enough to show that $\text{Hom}_C(M^*, f) : \text{Hom}_C(M^*, B) \to \text{Hom}_C(M^*, M)$ is surjective, that is, any map $h : M^* \to M$ factors through $f : B \to M$. Then consider the commutative diagram in Figure 5, where $t$ is obtained from the first lifting, and we get $s : B \to B$

Figure 5. Commutative diagram for the proof of Lemma 6.7

by using that $f : B \to M$ is a right add $T$-approximation. So $h = tg = fsg$, and hence $h : M^* \to M$ factors through $f : B \to M$, as desired. This finishes the proof of the lemma.

We now put the lemmas together to get the following.

**Theorem 6.8.** If $M$ is a complement of the almost complete basic tilting object $T$ in $C$, then $M^*$ is another complement, obtained by extending the minimal right add $T$-approximation to a triangle.

**Proof.** We only need to remark that $M \not\cong M^*$. This follows since $\text{Ext}^1_C(M, M^*) \neq 0$ and $\text{Ext}^1_C(M, M) = 0$.

It is clear that we can also get dual constructions. That is, start with a complement $M$, and consider the triangle

$M \xrightarrow{s} B' \xrightarrow{v} M'^* \to M[1],$

where $u : M \to B'$ is a minimal left add $T$-approximation. In a dual way we get that $v : B' \to M'^*$ is a minimal right add $T$-approximation, and that $M'^*$ is a complement of $T$ with $M \not\cong M'^*$. We then have the following consequence of the previous results.

**Proposition 6.9.** Let $M$ be a complement of the almost complete basic tilting object $T$ in $C$. Then $M^* \simeq M'^*$ is the unique other complement, where $M^*$ is the fibre of the minimal right add $T$-approximation of $M$ in $C$, and $M'^*$ is the cofibre of the minimal left add $T$-approximation of $M$ in $C$.

For an indecomposable exceptional module $M$, it is well known that the endomorphism ring $\text{End}_H(M)$ is a division ring. However, the endomorphism ring $\text{End}_C(M)$ need not be a division ring, which we later in this section observe in an example. However, if $H$ is of finite representation type, or more generally, if $M$ is (induced by) a preprojective or preinjective module, then $\text{End}_C(M)$ is a division ring. This is a special case of the following.

**Lemma 6.10.** Let $M$ be an indecomposable $H$-module with $\text{Hom}_D(M, \tau^2 M) = 0$. Then $\text{End}_C(M)$ is a division ring.

**Proof.** By Proposition 1.5, $\text{End}_C(M) = \text{Hom}_D(M, M) \oplus \text{Hom}_D(M, FM)$. Using the AR-formula and the assumption on $M$, we obtain

$\text{Hom}_D(M, FM) = \text{Hom}_D(M, \tau^{-1} M[1]) \cong D \text{Hom}_D(M, \tau^2 M) = 0$

and the claim follows.
We will need to consider the factor rings $D_M = \text{End}_{C}(M)/\text{rad}_{C}(M, M)$ and $D_{M^*} = \text{End}_{C}(M^*)/\text{rad}_{C}(M^*, M^*)$, which turn out to be isomorphic.

**Lemma 6.11.** There is a natural ring-isomorphism $D_M \to D_{M^*}$.

**Proof.** Consider the triangle

\[ \begin{array}{ccc}
M^* & \xrightarrow{\alpha} & B \\
\downarrow{\beta} & & \downarrow{\gamma} \\
M^* & \xrightarrow{\alpha} & B
\end{array} \]

Let $\alpha$ be an element in $\text{End}_{C}(M)$. Then there is a commutative diagram as in Figure 6, where $\gamma$ exists since $B \to M$ is a right add-$T$-approximation. We claim

\[ gwg = (\gamma_1 - \gamma_2)g = g(\beta_1 - \beta_2). \]

Since $M^*$ is not a summand of $B$, $wg$ is not an isomorphism. If $\beta_1 - \beta_2$ was an isomorphism, then $wg - (\beta_1 - \beta_2)$ would also be an isomorphism. But

\[ g(wg - (\beta_1 - \beta_2)) = 0, \]

so then $g = 0$, a contradiction, so the claim is proved.

Using that also $M^* \to B$ is a left add-$T$-approximation, we obtain that $\alpha \to \beta$ is an epimorphism. Assume now $\alpha$ is not an isomorphism, then there is an integer $N$ such that $\alpha^N = 0$ by Proposition 12. Thus, there is a commutative diagram as in Figure 7, which shows that $\beta^N$ is not an isomorphism, and thus $\beta$ is in $\text{rad}_{C}(M^*, M^*)$. It follows from the minimality of $B \to M$ that if $\alpha$ is an isomorphism, then $\gamma$ and hence $\beta$ are isomorphisms.

\[ \begin{array}{ccc}
B & \xrightarrow{\gamma^N} & M \\
\downarrow{0} & & \downarrow{\beta^N} \\
B & \xrightarrow{\alpha} & M
\end{array} \]
We want to show that in \( \mathcal{C} \) all non-isomorphisms \( M \to M \), actually factor through \( B \to M \). The following is useful for this.

**Lemma 6.12.** All maps in \( \text{rad}_\mathcal{C}(M, M) \) factor through \( B \to M \) if and only if all maps in \( \text{rad}_\mathcal{C}(M^*, M^*) \) factor through \( M^* \to B \).

**Proof.** Apply \( \text{Hom}_\mathcal{C}(M, ) \) to the triangle

\[
M^* \to B \to M \to M^*[1]
\]
to obtain the exact sequence

\[
\text{Hom}_\mathcal{C}(M, M^*) \to \text{Hom}_\mathcal{C}(M, B) \to \text{Hom}_\mathcal{C}(M, M) \to \text{Hom}_\mathcal{C}(M, M^*[1]) \to 0.
\]
Assume any \( f \in \text{rad}_\mathcal{C}(M, M) \) factors through \( B \to M \). This means that

\[
\text{Hom}_\mathcal{C}(M, M^*[1]) \cong \text{Hom}_\mathcal{C}(M/\text{rad}_\mathcal{C}(M, M), M).
\]
Applying \( \text{Hom}_\mathcal{C}(, M^*) \) to the same triangle gives the exact sequence

\[
\text{Hom}_\mathcal{C}(M, M^*) \to \text{Hom}_\mathcal{C}(B, M^*) \to \text{Hom}_\mathcal{C}(M^*, M^*) \to \text{Hom}_\mathcal{C}(M, M^*[1]) \to 0.
\]
which means that \( \text{Hom}_\mathcal{C}(M, M^*[1]) \cong \text{Hom}_\mathcal{C}(M^*, M^*)/I \) where \( I \) is the image of the map \( u \). It follows from Lemma 6.11 that \( I \) is the radical \( \text{rad}_\mathcal{C}(M^*, M^*) \). The other implication can be shown similarly. \( \square \)

We can now prove the promised result about lifting non-isomorphisms in \( \mathcal{C} \).

**Lemma 6.13.** With the previous notation and assumptions, any non-isomorphism \( M \to M \) in \( \mathcal{C} \) factors through \( B \to M \).

**Proof.** We can assume that \( \mathcal{T} \oplus M \) is induced by an \( H \)-module. We first assume that \( \mathcal{T} \) is sincere, so \( M^* \) is also induced by a module. By Lemma 6.2, the triangle \( \mathcal{T} \) is induced by an exact sequence of modules. We view this exact sequence as a triangle in \( \mathcal{D} \) and apply \( \text{Hom}_\mathcal{D}(F^{-1}M, ) \) to it. Since \( \text{Hom}_\mathcal{D}(F^{-1}M, M^*[1]) = \text{Hom}_\mathcal{D}(\tau M, M^*[2]) = 0 \), it follows that any non-isomorphism \( M \to M \) in \( \mathcal{C} \) factors through \( B \to M \), using Proposition 6.5.

Now assume that \( \mathcal{T} \) is not sincere. Then \( M^* \) is induced by an object \( P[1] \) in \( \mathcal{D} \), where \( P \) is an indecomposable projective \( H \)-module, and thus \( \text{rad}_\mathcal{C}(M^*, M^*) = 0 \), using Lemma 6.10. Applying Lemma 6.12, it follows trivially that also in this case, all non-isomorphisms \( M \to M \) in \( \mathcal{C} \) factor through \( B \to M \). \( \square \)

We can now conclude with the following property of \( \text{Ext}_\mathcal{C}^1(M, M^*) \).

**Proposition 6.14.** Let \( M \) and \( M^* \) be the complements of an almost complete tilting object in the cluster category \( \mathcal{C} \). Then \( \text{Ext}_\mathcal{C}^1(M, M^*) \) has dimension one over each of the division rings \( D_M = \text{End}_\mathcal{C}(M)/\text{rad}_\mathcal{C}(M, M) \) and \( D_{M^*} \).

**Proof.** Apply \( \text{Hom}_\mathcal{C}(M, ) \) to the triangle

\[
M^* \to B \to M \to M^*[1],
\]
to get the exact sequence

\[
\text{Hom}_\mathcal{C}(M, M^*) \to \text{Hom}_\mathcal{C}(M, B) \to \text{Hom}_\mathcal{C}(M, M) \to \text{Ext}_\mathcal{C}^1(M, M^*) \to \text{Ext}_\mathcal{C}^1(M, B)
\]
where \( \text{Ext}_\mathcal{C}^1(M, B) = 0 \). Isomorphisms \( M \to M \) do not lift to \( B \), since \( M \) is not a summand of \( B \). Thus, it follows from Lemma 6.13 that \( \text{Ext}_\mathcal{C}^1(M, M^*) \cong \text{End}_\mathcal{C}(M)/\text{rad}_\mathcal{C}(M, M) \). It follows similarly that \( \text{Ext}_\mathcal{C}^1(M, M^*) \) is one-dimensional over \( \text{End}_\mathcal{C}(M^*) \). \( \square \)
Note that for the triangle
\[ M^* \to B \to M \to M^*[1]\]
it may happen that \( B \) is zero, even though \( \text{Ext}_C^1(M, M^*) \neq 0 \). This of course means that \( M \simeq M^*[1] = \tau M^* \), so in this case the second triangle \( \tau M^* = M \to B' \to M^* \) is almost split.

We also notice that Lemma 6.13 has the following interpretation.

**Corollary 6.15.** Let \( T \) be a tilting object in a cluster category \( C \) for a hereditary algebra over an algebraically closed field. Then the quiver of \( \text{End}_C(T)^{\text{op}} \) has no loops.

**Example.** The following example illustrates Theorem 6.8 in the tame hereditary case. We consider the quiver \( \widetilde{D}_4 \) with the orientation as in Figure 8. Let \( \Lambda \) be the path algebra of the above quiver over some field \( k \). Let \( P_i \) be the indecomposable projective corresponding to vertex \( i \). Then it easy to see that
\[
T = P_4 \prod P_5 \prod \tau^{-1} P_2 \prod \tau^{-1} P_3
\]
is an almost complete basic tilting module, and thus an almost complete basic tilting object in the corresponding category \( C \).

It is clear that \( \overline{T} \) is sincere, and one complement is easy to find, namely \( P_1 \). We use the above approach to find the other complement.

Let \( R \) be the cokernel of the embedding \( P_1 \to \tau^{-1} P_2 \prod \tau^{-1} P_3 \). Then \( R \) is a regular exceptional module with composition factors \( S_1, S_4, S_5 \). In the AR-quiver it is at the mouth of a tube of rank two, so \( \tau^2 R \simeq R \). Thus, \( R \) is an example of an indecomposable exceptional object, with \( \text{End}_C(R) \) not a division ring.

In \( \text{mod} \Lambda \) there are exact sequences
\[
0 \to P_1 \to \tau^{-1} P_2 \prod \tau^{-1} P_3 \to R \to 0
\]
and
\[
0 \to P_4 \prod P_5 \to P_1 \to \tau R \to 0.
\]
Thus, in \( D \) there are triangles
\[
P_1 \to \tau^{-1} P_2 \prod \tau^{-1} P_3 \to R \to P_1[1]
\]
and
\[
F^{-1} R \to P_4 \prod P_5 \to P_1 \to F^{-1} R[1].
\]
The images of these triangles in \( C \) are exactly the triangles described in Theorem 6.8.

Thus, we obtain that the other complement of \( \overline{T} \) is \( R \), and \( B \) and \( B' \) are given by \( P_4 \prod P_5 \) and \( \tau^{-1} P_2 \prod \tau^{-1} P_3 \) respectively.

If we let \( T = \overline{P}_{1 \prod P_1} \) and \( T' = \overline{P}_{1 \prod R} \), then the endomorphism ring \( \text{End}_C(T)^{\text{op}} \) is the path algebra of the quiver in Figure 9, while \( \text{End}_C(T')^{\text{op}} \) is the path algebra of
the quiver in Figure 10 with relations $ac - bf, ec - df, ga - he, gb - hd, cg, ch, fg, fh$.

Figure 9. The quiver of $\text{End}_C(T)^{\text{op}}$

Figure 10. The quiver of $\text{End}_C(T')^{\text{op}}$

7. Description of exchange pairs

As usual let $H$ be a hereditary finite dimensional algebra, and $C$ the factor category $D^b(H)/F$, with $F = \tau^{-1}[1]$. We say that two non-isomorphic indecomposable objects in $C$ form an exchange pair if they are complements of the same almost complete basic tilting object. In this language, we have seen that if $M$ and $M^*$ form an exchange pair, then $\text{Ext}^1_C(M, M^* \simeq \text{Ext}^1_C(M^*, M)$ is one-dimensional over $D_M = \text{End}_C(M)/\text{rad}_C(M, M)$ and over $D_{M^*}$. We now want to show that also the converse holds.

Assume that $M, M^*$ are exceptional and that $\text{Ext}^1_C(M, M^*) = \text{Ext}^1_C(M^*, M)$ is one-dimensional over $D_M$ and over $D_{M^*}$. We can therefore choose non-split triangles:

(1) $M^* \to B \to M \to M^*[1]$

and

(2) $M \to B' \to M^* \to M[1]$

in $C$, where we use the same notation as before. We want to find an almost complete basic tilting object $\overline{T}$ having $M$ and $M^*$ as complements. We start building up $\overline{T}$ by showing that $B \bigsqcup B' \bigsqcup M$ and $B \bigsqcup B' \bigsqcup M^*$ are exceptional objects in $C$.

Lemma 7.1. In the above notation we have:

$$\text{Ext}^1_C(B \bigsqcup B' \bigsqcup M, B \bigsqcup B' \bigsqcup M) = 0$$

and

$$\text{Ext}^1_C(B \bigsqcup B' \bigsqcup M^*, B \bigsqcup B' \bigsqcup M^*) = 0.$$
Proof. Apply $\text{Hom}_C(M,\cdot)$ to (1) to get the exact sequence

$$\text{Hom}_C(M, M^*) \to \text{Hom}_C(M, B) \to \text{Hom}_C(M, M) \xrightarrow{\alpha} \text{Ext}_1^C(M, M^*) \to \text{Ext}_1^C(M, B) \to \text{Ext}_1^C(M, M).$$

Since $\alpha \neq 0$ and $\dim_{D_M} \text{Ext}_1^C(M, M^*) = 1$, while $\text{Ext}_1^C(M, M) = 0$ by assumption, it follows that $\text{Ext}_1^C(M, M^*) = 0$. Analogously, we get $\text{Ext}_1^C(M^*, B') = 0$.

Apply $\text{Hom}_C(\cdot, M^*)$ to (1) to get the exact sequence

$$\text{Hom}_C(M, M^*) \to \text{Hom}_C(B, M^*) \to \text{Hom}_C(M^*, M^*) \xrightarrow{\beta} \text{Ext}_1^C(M, M^*) \to \text{Ext}_1^C(B, M^*) \to \text{Ext}_1^C(M^*, M^*).$$

Since $\beta \neq 0$ and $\dim_{D_M} \text{Ext}_1^C(M^*, M^*) = 1$, while $\text{Ext}_1^C(M^*, M^*) = 0$ by assumption, we get $\text{Ext}_1^C(B, M^*) = 0$. Analogously, we get from (2) that $\text{Ext}_1^C(B', M) = 0$.

Apply $\text{Hom}_C(B \bigsqcup B', \cdot)$ to (1) to get the exact sequence

$$\text{Ext}_1^C(B \bigsqcup B', M^*) \to \text{Ext}_1^C(B \bigsqcup B', B) \to \text{Ext}_1^C(B \bigsqcup B', M),$$

and hence $\text{Ext}_1^C(B \bigsqcup B', B) = 0$. Apply $\text{Hom}_C(B \bigsqcup B', \cdot)$ to (2) to get the exact sequence

$$\text{Ext}_1^C(B \bigsqcup B', M) \to \text{Ext}_1^C(B \bigsqcup B', B') \to \text{Ext}_1^C(B \bigsqcup B', M^*),$$

and hence $\text{Ext}_1^C(B \bigsqcup B', B') = 0$. This finishes the proof of the lemma. \qed

We remark that this implies that $M$ and $M^*$ cannot be direct summands of $B \bigsqcup B'$. We have that $B \bigsqcup B'$ is an exceptional object in $\mathcal{C}$, and hence can be extended to a tilting object by Lemma 3.2. So let $T'$ be a complement in $\mathcal{C}$, that is $T = B \bigsqcup B' \bigsqcup T'$ is a tilting object in $\mathcal{C}$. We want to show that either $M$ or $M^*$ is a direct summand of $T$ and if we remove all copies of this summand, we get a new tilting object by adding the other one.

The proof of this is based upon the following crucial result. Here, for $X$ an object of $\mathcal{C}$, $\text{Supp}_C(\cdot, X)$ denotes the objects in $\mathcal{C}$ which have a non-zero homomorphism to $X$.

**Lemma 7.2.** With the above notation, we have

$$\text{Supp}_C(\cdot, \tau M) \subset \{M^*\} \cup \text{Supp}_C(\cdot, \tau B) \cup \text{Supp}_C(\cdot, \tau B').$$

**Proof.** Consider the triangles

$$M^* \xrightarrow{\delta_2} B \xrightarrow{\delta_1} M \to M^*[1]$$

and

$$M \to B' \to M^* \to M[1].$$

Rewrite the last triangle as

$$M^* \xrightarrow{b_1} \tau M \xrightarrow{b_2} \tau B' \to M^*[1]$$

where we use that $M^*[1] = \tau^{-1} M^*$ and $\tau M^* = M^*[1]$ in $\mathcal{C}$. This gives rise to an exact sequence of functors

$$\text{Hom}_C(\cdot, M^*) \to \text{Hom}_C(\cdot, \tau M) \to \text{Hom}_C(\cdot, \tau B') \to \text{Hom}_C(\cdot, M^*[1]) \to \cdots.$$  

Assume that $X$ is an indecomposable object which is not isomorphic to $M^*$, and which is in $\text{Supp}_C(\cdot, \tau M)$, and let $s \in \text{Hom}_C(X, \tau M)$ be a non-zero map.

If $k s : X \to \tau B'$ is not zero, then $X$ is in $\text{Supp}_C(\cdot, \tau B')$. If $k s = 0$, then there is some $s' : X \to M^*$ such that $s = h s'$. Denote by

$$\tau M^* \xrightarrow{\alpha} A \xrightarrow{\beta} M^* \to \tau M^*[1]$$
the almost split triangle in $C$ for $M^*$. Since $X \not\cong M^*$, there is some map $s'' : X \to A$ such that $s' = rs''$. Consider the commutative diagram in Figure 11 where the map $b_1 : A \to \tau B$ exists since the first triangle is almost split and the second one is not split, and $b_2$ is then the induced map.

We claim that the map $b_1s'' : X \to A \to \tau B$ is nonzero. Note that $(\tau f)b_1s'' = b_2rs'' = b_2s'$. Since $\text{Ext}^1_C(M,M^*)$ has dimension one over $D_M$, it follows that $\text{Hom}_C(M^*,\tau M)$ also has dimension one. Since $b_2$ and $h$ are both nonzero elements in $\text{Hom}_C(M^*,\tau M)$, it follows that there is a nonzero map $\phi : \tau M \to \tau M$, necessarily an isomorphism, such that $b_2 = \phi k$. Hence $b_2s' = \phi hs' = \phi s \neq 0$, and consequently $b_1s'' \neq 0$. This finishes the proof of the lemma.

We need some additional preliminary results.

**Lemma 7.3.** Let the assumptions and notation be as before.

(a) $\text{Ext}^1_C(M,T_i) = 0$ for any indecomposable summand $T_i$ of $T$ which is not isomorphic to $M^*$.

(b) $\text{Ext}^1_C(M^*,T_i) = 0$ for any indecomposable summand $T_i$ of $T$ which is not isomorphic to $M$.

*Proof.* (a) Assume to the contrary that $\text{Ext}^1_C(M,T_i) \neq 0$ for some $T_i$ an indecomposable summand of $T$, with $T_i \not\cong M^*$. We have $\text{Ext}^1_C(M,T_i) \simeq D \text{Hom}_C(T_i,\tau M) \neq 0$, and hence by Lemma 7.2 either $\text{Hom}_C(T_1,\tau B) \neq 0$ or $\text{Hom}_C(T_1,\tau B') \neq 0$, so that $\text{Ext}^1_C(B,T_1) \neq 0$ or $\text{Ext}^1_C(B',T_1) \neq 0$. But this contradicts the fact that $B \coprod B' \coprod T'$ is exceptional, and the claim follows.

(b) The proof is dual to the proof of (a). \qed

We can now get the following.

**Lemma 7.4.** If $M^*$ is not a direct summand of $T$, then $M$ is a direct summand of $T$, and if $T = M^k \coprod \overline{T}$ (with $M$ not a direct summand of $\overline{T}$), then $M^* \coprod \overline{T}$ is also a tilting object.

*Proof.* Assume that $M$ and $M^*$ are not summands of $T$. Then by Lemma 7.3 $T \coprod M$ is exceptional, contradicting the fact that $T$ is a tilting object.

Assume still that $M^*$ is not a summand of $T$, so that $T = M^k \coprod \overline{T}$ where $M$ is not a summand of $\overline{T}$ and $k > 0$. By Lemma 7.3 $M^* \coprod \overline{T}$ is an exceptional object with the “correct” number of indecomposable non-isomorphic direct summands, and is hence a tilting object. \qed

Summarising, we now have the following.

**Theorem 7.5.** Two exceptional indecomposable objects $M$ and $M^*$ form an exchange pair if and only if $\dim_{D_M} \text{Ext}^1_C(M,M^*) = 1 = \dim_{D_M} \text{Ext}^1_C(M^*,M)$.

The following example shows that it is necessary to assume that both $\text{Ext}^1$-spaces are one-dimensional, that is, one is not the consequence of the other.
Example. Consider the ring

\[ H = \left( \begin{array}{cc} \mathbb{R} & 0 \\ \mathbb{R}C & \mathbb{C} \end{array} \right). \]

The AR-quiver of \( D^b(H) \) is shown in Figure 12. We have

\[ \dim \text{Ext}_C^1\left( \begin{array}{c} \mathbb{R} \\ 0 \end{array}, \begin{array}{c} \mathbb{C} \end{array} \right) = 1 \]

and

\[ \dim \text{Ext}_C^1\left( \begin{array}{c} \mathbb{R} \\ 0 \end{array}, \begin{array}{c} \mathbb{C} \end{array} \right) = 2. \]

Hence \( \left\{ \begin{array}{c} \mathbb{R} \\ 0 \end{array}, \begin{array}{c} \mathbb{C} \end{array} \right\} \) is not an exchange pair.

Finally, suppose that \( H \) is the path algebra of a quiver of simply-laced Dynkin type \( \Delta \) with an alternating orientation. Let \( \mathcal{A}(\Delta) \) denote the corresponding cluster algebra. By Proposition 4.1, we know that there is a 1–1 correspondence between the cluster variables of \( \mathcal{A}(\Delta) \) and \( \text{ind}\mathcal{C} \). By Theorem 4.5 we know that this induces a bijection between the basic tilting objects of \( \mathcal{C} \) and the clusters of \( \mathcal{A}(\Delta) \). We have the following interpretation of Theorem 7.5.

**Theorem 7.6.** [FZ2, 3.5, 4.4] Suppose \( \mathcal{A}(\Delta) \) is the cluster algebra associated to an arbitrary Dynkin diagram of simply-laced type. Let \( x, y \) be two cluster variables of \( \mathcal{A}(\Delta) \). Then \( x, y \) form an exchange pair if and only if their compatibility degree is equal to 1.

### 8. Graphical calculus

In this section, we assume the quiver \( Q \) to be of simply-laced Dynkin type. We shall give a graphical calculus for computing the triangles in Section 6 (see Theorem 6.8 and the comment afterwards).

Suppose that \( M, M^* \) are indecomposable objects of \( \mathcal{C} = D^b(kQ)/F \). We know that \( \text{End}_\mathcal{C}(M) \simeq \text{End}_\mathcal{C}(M^*) \simeq k \) — use Proposition 1.7(c) and the fact that every indecomposable object in \( \mathcal{C} \) is in the \( \tau \)-orbit of an indecomposable projective module. Suppose that \( \text{Ext}_C^1(M^*, M) \) is one-dimensional over \( k \). We know by Theorem 7.5 that this is the equivalent to assuming that \( M, M^* \) are the two complements of an almost complete basic tilting object \( T \) of \( \mathcal{C} \). We would like to construct triangles:

\[ M^* \xrightarrow{g} B \xrightarrow{f} M \rightarrow M^*[1] \]
and
\[(7) \quad M \xrightarrow{u} B' \xrightarrow{v} M^* \rightarrow M[1]\]
where \(f : B \rightarrow M\) is a minimal right add \(\mathcal{T}\)-approximation of \(M\), and \(u : M \rightarrow B'\) is a minimal left add \(\mathcal{T}\)-approximation of \(M\).

Without loss of generality (by applying APR-tilts if necessary), we can assume that \(M\) is a simple projective \(kQ\)-module \(P\). Suppose first that \(M^* = P'[1]\) is the shift of an indecomposable projective \(kQ\)-module \(P'\). Then
\[
\text{Ext}_{kQ}^1(M^*, M) = \text{Hom}_{kQ}(P', P)
\]
(see Proposition [14] (d)), since \(P'\) is projective. But, since \(P\) is simple projective, this is non-zero (and necessarily one-dimensional) if and only if \(P \cong P'\). By applying the autoequivalence \(\tau_C^{-1}\) to \(P\) and \(P'[1]\) we are reduced to the situation where \(M\) and \(M^*\) are the start and end terms respectively of an almost split sequence of \(kQ\)-modules. We are then in the case discussed after the proof of Proposition [6,13] and we see that \(B = 0\) and \(B'\) is the middle term of the almost split sequence involving \(M\) and \(M^*\).

We are now left with the case where \(M\) and \(M^*\) are both modules over \(kQ\), with \(M\) projective. By Proposition [14] (c), we have:
\[
\text{Ext}_{kQ}^1(M^*, M) \simeq \text{Ext}_{kQ}^1(M^*, M) \prod \text{Ext}_{kQ}^1(M, M^*).
\]
Since \(M\) is projective, \(\text{Ext}_{kQ}^1(M, M^*) = 0\). Then we have a unique non-trivial extension
\[
0 \rightarrow M \rightarrow E \rightarrow M^* \rightarrow 0
\]
of \(kQ\)-modules. There is a corresponding triangle
\[
M \rightarrow E \rightarrow M^* \rightarrow M[1]
\]
in \(\mathcal{D}\) which induces a non-split triangle in \(\mathcal{C}\). Since the triangle \(7\) is (up to isomorphism) the unique non-split triangle in \(\mathcal{C}\) with start term \(M\) and end term \(M^*\), we have that \(E\) is isomorphic to \(B'\). In the case where \(\text{Ext}_{kQ}^1(M, M^*) \simeq k\) we obtain a middle term isomorphic to \(B\). Note that by switching the roles of \(M\) and \(M^*\) (using Proposition [14] (b)), and applying \(\tau_C\) as appropriate, we can compute both middle terms \(B\) and \(B'\) using the module category alone. We have reduced the problem to the following:

**Problem 8.1.** Let \(Q\) be a simply-laced Dynkin quiver, and let \(M, M^*\) be indecomposable \(kQ\)-modules satisfying \(\text{Ext}_{kQ}^1(M, M^*) \simeq k\) (and therefore \(\text{Ext}_{kQ}^1(M^*, M) = 0\)). Compute the middle term of the unique non-trivial extension represented by a non-zero element of \(\text{Ext}_{kQ}^1(M, M^*)\).

Let \(M\) and \(M^*\) be indecomposable \(kQ\)-modules such that \(\dim \text{Ext}_{kQ}^1(M, M^*) = 1\), and let
\[
\zeta : 0 \rightarrow M^* \rightarrow X \rightarrow M \rightarrow 0
\]
be the unique non-trivial extension mentioned above. We will now develop a graphical method (in terms of the AR-quiver) for the determination of \(X\). We recall that the starting function \(s_U\) of an indecomposable \(kQ\)-module \(U\) is defined as the function \(V \mapsto \dim \text{Hom}_{kQ}(U, V)\) on indecomposable \(kQ\)-modules. All such starting functions are depicted in [15,2]. Similarly, the ending function \(e_U\) is defined as the function \(V \mapsto \dim \text{Hom}_{kQ}(V, U)\).

**Lemma 8.2.** Let \(U\) and \(V\) be indecomposable representations of \(kQ\) such that \(\text{Hom}_{kQ}(U, V) \neq 0\) and \(\text{Ext}_{kQ}^1(V, U) = 0\). Then \(\dim \text{Hom}_{kQ}(U, V) = 1\).
Proof. The above condition translates to
\[ s_U(V) \neq 0, \quad s_U(\tau V) = 0 \]
by the AR-formula. Now direct inspection of the tables in [Bo2] gives the above result. \qed

This result can also be established in a theoretical way, using the result [vH, Corollary to main Theorem]. Since the table in [Bo2] will play a central role in the following, the above proof is more adapted to the theme of this section.

Proposition 8.3. Let \( M, M^* \) and \( X \) be as above. Then \( X \) is the direct sum of one copy of each indecomposable \( kQ \)-module \( V \) fulfilling
\[ \text{Hom}_{kQ}(M^*, V) \neq 0 \neq \text{Hom}_{kQ}(V, M) \quad \text{and} \quad \text{Ext}_{kQ}^1(V, M^*) = 0 = \text{Ext}_{kQ}^1(M, V). \]

Proof. Let \( V \) be an indecomposable direct summand of \( X \). We first show that the stated homological conditions on \( V \) are satisfied. If \( \text{Hom}_{kQ}(M^*, V) = 0 \), then \( V \) has to appear as a direct summand of \( M \). Since \( M \) is indecomposable, this implies \( M = V \), and the sequence \( \zeta \) splits, a contradiction. Thus \( \text{Hom}_{kQ}(M^*, V) \neq 0 \).

In the induced exact sequence
\[ \text{Hom}_{kQ}(M^*, M^*) \xrightarrow{d} \text{Ext}_{kQ}^1(M, M^*) \xrightarrow{\text{Ext}_{kQ}^1(X, M^*)} \text{Ext}_{kQ}^1(M^*, M^*) = 0, \]
the map \( d \) is surjective, since \( \text{Ext}_{kQ}^1(M, M^*) \) is one-dimensional and the sequence \( \zeta \) is non-split. Thus \( \text{Ext}_{kQ}^1(X, M^*) = 0 \), and in particular \( \text{Ext}_{kQ}^1(V, M^*) = 0 \). We can argue dually to obtain the other two conditions on \( V \).

Enumerate the isomorphism classes of indecomposables with the above properties as \( \{V_1, \ldots, V_s\} \); thus we can write \( X = \bigoplus_{i=1}^s V_i^{m_i} \), and we have to prove that \( m_i = 1 \) for all \( i = 1 \ldots s \). Consider the induced exact sequence
\[ 0 \to \text{Hom}_{kQ}(M, X) \to \text{Hom}_{kQ}(X, X) \to \text{Hom}_{kQ}(M^*, X) \to \text{Ext}_{kQ}^1(M, X). \]
From the above, we can conclude that \( \text{Ext}_{kQ}^1(M, X) = 0 \). Since any \( V_i \) maps to \( M \), we also have \( \text{Hom}_{kQ}(M, X) = 0 \), thus \( \text{Hom}_{kQ}(M, V_i) = 0 \) since the category \( \text{mod} kQ \) is representation-directed. We arrive at an isomorphism
\[ \text{Hom}_{kQ}(X, X) \cong \text{Hom}_{kQ}(M^*, X). \]
Since \( \text{End}_{kQ}(X) \) contains the semisimple ring \( \oplus_{i=1}^s M_{m_i}(\text{End}_{kQ}(V_i)) \) as a subring, we can estimate:
\[
\sum_{i=1}^s m_i^2 \leq \sum_{i,j=1}^s m_i m_j \dim \text{Hom}_{kQ}(V_i, V_j) = \dim \text{Hom}_{kQ}(X, X) = \\
= \dim \text{Hom}_{kQ}(M^*, X) = \sum_{i=1}^s m_i \dim \text{Hom}_{kQ}(M^*, V_i) = \sum_{i=1}^s m_i,
\]
using Lemma [2]. Thus \( m_i \in \{0, 1\} \) for all \( i = 1 \ldots s \), and \( \text{Hom}_{kQ}(V_i, V_j) = 0 \) whenever \( i \neq j \) and \( m_i = 1 = m_j \).

Similarly, we see that for each \( i = 1 \ldots s \), we have isomorphisms
\[ \text{Hom}_{kQ}(X, V_i) \cong \text{Hom}_{kQ}(M^*, V_i) \quad \text{and} \quad \text{Hom}_{kQ}(V_i, X) \cong \text{Hom}_{kQ}(V_i, M). \]
Given a fixed \( V_i \), we choose non-zero maps \( f : M^* \to V_i \) and \( g : V_i \to M \). The above isomorphisms yield factorisations \( f = r_0 \alpha \) and \( g = \beta s \), where \( \alpha : M^* \to X \) and \( \beta : X \to M \) are the maps in the short exact sequence \( \zeta \). Since \( r \neq 0 \) and \( s \neq 0 \) we can choose summands \( V_j \) and \( V_k \) of \( X \) such that \( r_j \alpha \neq 0 \) and \( \beta s_k \neq 0 \), where \( r_j \) is the restriction of \( r \) to \( V_j \) and \( s_k \) is the composition of \( s \) with the projection onto \( V_k \).
It is enough to prove that \( skr_j \neq 0 \). Then, since \( V_j \) and \( V_k \) are direct summands of \( X \), we obtain from the above that \( j = k \), and therefore that \( i = j = k \) since there are no oriented cycles of homomorphisms in the category of \( kQ \)-modules.

We have \( \operatorname{Ext}^1_{kQ}(M, V_i) = 0 \) by assumption, and \( \operatorname{Ext}^1_{kQ}(M^*, V_i) = 0 \) since \( kQ \) is representation-directed and \( \operatorname{Hom}_{kQ}(M^*, V_i) \neq 0 \). These two facts together imply \( \operatorname{Ext}^1_{kQ}(X, V_i) = 0 \), thus in particular \( \operatorname{Ext}^1_{kQ}(V_k, V_i) = 0 \), since \( V_k \) is a direct summand of \( X \). This vanishing condition allows us to apply the Happel-Ringel Lemma \([HR]\) to conclude that \( sk \neq 0 \) must be mono or epi. If \( sk \) is mono, then \( skl_j \neq 0 \) since \( r_j \neq 0 \), and we are done. So assume that \( sk \) is epi. By possibly applying the AR-translate, we can assume without loss of generality that \( M^* \) is projective. This provides us with a surjection

\[
(s_k \circ \_): \operatorname{Hom}_{kQ}(M^*, V_i) \to \operatorname{Hom}_{kQ}(M^*, V_k),
\]

thus an isomorphism since both spaces are one-dimensional by Lemma \( 8.2 \). But this implies that \( skl_j \neq 0 \). This finishes the proof.

\[\square\]

The starting and ending functions of an indecomposable \( kQ \)-module \( U \) can be computed in terms of the AR-quiver: the function \( s_U \) is determined by defining \( s_U(V) = 1 \) on the slice starting in \( U \), and by additivity \( s_U(\tau^{-1}(V)) = \sum_i s_U(C_i) - s_U(V) \) for a mesh \( V \to \oplus_i C_i \to \tau^{-1}V \). We can now define:

**Definition 8.4.** The starting frame \( F_s(U) \) (resp. the ending frame \( F_e(U) \)) of an indecomposable \( kQ \)-module \( U \) consists of all vertices \( V \) of the AR-quiver such that \( s_U(V) \neq 0 = s_U(\tau V) \) (resp. \( e_U(V) \neq 0 = e_U(\tau^{-1}V) \)).

As an immediate corollary to the above proposition, we get:

**Corollary 8.5.** Given indecomposables \( M \) and \( M^* \) such that \( \operatorname{Ext}^1_{kQ}(M, M^*) \) is one-dimensional, the unique non-trivial extension \( X \) of \( M \) by \( M^* \) is given as the direct sum of all indecomposables belonging to the intersection \( F_s(M^*) \cap F_e(M) \).

The starting and ending frames can now be worked out using the tables in \([Bo2]\). In type \( A \), they are easily seen to coincide with the slice starting (resp. ending) in an indecomposable. For type \( D \) and \( E \), the frames look in general more complicated. Below, we first show two ”typical” examples in type \( D_8 \). The starting frame of the respective minimal vertex of the picture is shown (the solid circles), embedded in a portion of the AR-quiver.

![Diagram](image)

Finally, we show the ”most complicated” starting frame in type \( E_8 \):
9. Interpretation and conjectures

In this section we will consider further links with cluster algebras, including interpretations of some of the preceding results. We will make some conjectures in this direction and also provide some examples giving supporting evidence for the conjectures.

Let $H$ be a finite dimensional hereditary algebra, with quiver $\Gamma$. For vertices $i$ and $j$ of $\Gamma$, let $n_{ij}$ denote the number of arrows from $i$ to $j$ in $\Gamma$. Let $X$ be the matrix with rows and columns indexed by the vertices of $\Gamma$ (we choose a total ordering):

$$x_{ij} = \begin{cases} n_{ij} & n_{ij} \neq 0, \\ -n_{ji} & n_{ij} = 0. \end{cases}$$

Let $\mathcal{A}(H)$ be the corresponding cluster algebra. Let $\mathcal{C}$ be the cluster category associated to $H$.

**Conjecture 9.1.** There is a 1–1 correspondence between the cluster variables of $\mathcal{A}(H)$ and $\text{ind}\mathcal{C}$ inducing a 1–1 correspondence between the clusters of $\mathcal{A}(H)$ and the basic tilting objects in $\mathcal{C}$.

We have seen (see Section 4) that this conjecture holds in the case where $H$ is the path algebra of a simply-laced Dynkin quiver. In this case, we make a further conjecture:

**Conjecture 9.2.** Let $C$ be a cluster of the cluster algebra of simply-laced Dynkin type, and let $T$ be the corresponding tilting object of the cluster category $\mathcal{C}$ of the same type. Let $A_C$ denote the algebra associated to $C$ in [CCS, Section 1] (its module category is denoted $\text{Mod} Q_C$ there). Then $\text{End}_C(T)^{\text{op}}$ is isomorphic to $A_C$.

Suppose that $\overline{T}$ is an almost complete basic tilting object of $\mathcal{C}$. Let $M, M^*$ be the complements of $\overline{T}$, and let

$$M^* \xrightarrow{\varrho} B \xrightarrow{\varphi} M \rightarrow M^*[1]$$

and

$$M \xrightarrow{\varrho} B' \xrightarrow{\varphi} M^{**} \rightarrow M[1]$$

be the triangles $[\mathfrak{g}]$ and $[\mathfrak{m}]$ from Section 6.

We make the following conjecture:

**Conjecture 9.3.** In the above situation, let $B = \prod_{i \in I} B_i^{d_i}$ (respectively, $B' = \prod_{j \in J} (B_j')^{e_j}$) be the direct sum decomposition of $B$ (respectively, $B'$), where the $B_i$ are all non-isomorphic and the $B_j'$ are all non-isomorphic. Let $x, x'$ be the cluster variables corresponding to $M, M^*$, and for $i \in I$ (respectively, $j \in J$) let $x_i$ (respectively, $x'_j$) be the cluster variable corresponding to $B_i$ (respectively, $B_j'$).

Then the exchange relation in the cluster algebra $\mathcal{A}(H)$ (see equation 11 in the introduction) takes the form:

$$xx' = \prod_{i \in I} x_i^{d_i} + \prod_{j \in J'} (x'_j)^{e_j}.$$  

In particular, $B$ and $B'$ should have no common direct summands.
We note that in the simply-laced Dynkin case, this conjecture can be refor-
mulated, via the discussion in Section 8, to give a conjecture providin
g a direct interpretation of the cluster exchange relation in terms of short exact sequen-
ces of $kQ$-modules (see Problem 8.1). We also note that if Conjecture 9.3 holds then
it can be seen that the rule for matrix mutation (see the introductio
n) describes
the change in the quiver of the algebra $\text{End}_C(T)^{op}$ when one indecomposable direct
summand of the basic tilting object $T$ is exchanged for another. We give an exa
mple of this below. Finally, we remark that if Conjectures 9.1 and 9.3 bot
h hold, then
Theorems 1.11 and 1.12 (without coefficients) in [FZ2] hold for the cor
responding
cluster algebra.

Example. Let $H$ be the path algebra of the quiver as shown in Figure 13. Then
the corresponding cluster algebra $\mathcal{A}(H)$ has seed given by the transcendence basis
$\{u_1, u_2, u_3\}$ of $\mathbb{Q}(u_1, u_2, u_3)$ and matrix
\[
X = \begin{pmatrix}
0 & 1 & 1 \\
-1 & 0 & 1 \\
-1 & -1 & 0
\end{pmatrix}.
\]
The corresponding cluster algebra was investigated in [FZ1] 7.8 — the brick wall
example. Let $P_1, P_2, P_3$ denote the indecomposable projective modules correspon
ding to the vertices of the graph of $H$. Let $R$ denote the regular indecomposable
module with dimension vector $(1, 0, 1)$. Then $T = \tilde{P}_1 \bigsqcup \tilde{P}_2 \bigsqcup \tilde{P}_3$ is a basic tilting
object of $C$. Choosing $M = \tilde{P}_2$ and $T = \tilde{P}_1 \bigsqcup \tilde{P}_3$ we see that $\tilde{P}_2 \rightarrow \tilde{P}_1$ is a minimal
left add($T$)-approximation of $\tilde{P}_2$ and obtain the triangle:
\[
\tilde{P}_2 \rightarrow \tilde{P}_1 \rightarrow R \rightarrow \tilde{P}_2[1]
\]
in $C$. It follows that $T' = \tilde{T}_1 \bigsqcup \tilde{R} \bigsqcup \tilde{P}_3$ is again a basic tilting object of $C$. The
matrix $X'$ of the quiver of $\text{End}(T')^{op}$ corresponding to $T'$ is:
\[
X' = \begin{pmatrix}
0 & -1 & 2 \\
1 & 0 & -1 \\
-2 & 1 & 0
\end{pmatrix},
\]
which is easily seen to be the mutation of the matrix $X$ at 2.

Suppose that $H$ is a finite dimensional hereditary algebra, $\overline{T}$ is an almost com
plete basic tilting object of $C$, and $M$ and $M^*$ are the two complements of $\overline{T}$. Let
$T = \overline{T} \bigsqcup M$ and $T' = \overline{T} \bigsqcup M^*$ be the two completions of $\overline{T}$ to a basic tilting
object. Let $\Gamma = \text{End}_C(T \bigsqcup M)^{op}$ and $\Gamma' = \text{End}_C(T \bigsqcup M^*)^{op}$ be the endomorphism
algebras, taken over $C$. Denote by $S_M$ (respectively, $S_{M^*}$) the simple top of the
$\Gamma$-module $\text{Hom}_C(T, M)$ (respectively, the $\Gamma'$-module $\text{Hom}_C(T, M^*)$). Then we con
jecture that the category of $\Gamma$-modules and the category of $\Gamma'$-modules are related in the following way:

**Conjecture 9.4.** The categories $\text{mod} \, \Gamma / \text{add} \, S_M$ and $\text{mod} \, \Gamma' / \text{add} \, S_{M^*}$ are equi
valent.

This can be viewed as a generalisation of APR-tilting [APR].
Example. We give an example illustrating Conjecture 9.4. Take $\Delta$ to be the Dynkin diagram of type $A_3$. Then the AR-quiver of $\mathcal{C}$ is given in Figure 11. Let $T$ be the direct sum of the indecomposable objects corresponding to the filled-in circles in Figure 14(a) and let $T'$ be the direct sum of the indecomposable objects corresponding to the filled-in circles in Figure 14(b). Thus $T$ is the almost complete basic tilting object which is the direct sum of the objects corresponding to the two filled-in circles common to $T$ and $T'$. Here we display the AR-quiver of $\mathcal{C}$ slightly differently in order to demonstrate this example (noting that it appears on a Möbius band).

The AR-quivers of $\Gamma = \text{End}_{\mathcal{C}}(T)^{\text{op}}$ and $\Gamma' = \text{End}_{\mathcal{C}}(T')^{\text{op}}$ are given in Figure 15. The two vertices labelled by a “$+$” are identified, and the simples $S_M$ and $S_{M^*}$ are shown by filled-in circles. We can see that the full sub-translation quiver of the AR-quiver of $\Gamma$ consisting of all of the vertices except $S_M$ is isomorphic to the full sub-translation quiver of $\Gamma'$ consisting of all of the vertices except $S_{M^*}$. See Figure 16.

This also gives a nice example of mutation. The quivers of $\Gamma$ and $\Gamma'$ are shown in Figure 17. $\Gamma$ has no relations, but for $\Gamma'$ the relations are that the product of any pair of composable arrows is zero. The corresponding mutation is the mutation at 2 of the matrix $X$ to $X'$, where

$$X = \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix}, \quad X' = \begin{pmatrix} 0 & -1 & 1 \\ 1 & 0 & -1 \\ -1 & 1 & 0 \end{pmatrix}.$$
