LINEAR SPACES ON HYPERSURFACES
OVER NUMBER FIELDS

JULIA BRANDES

Abstract. We establish an analytic Hasse principle for linear spaces of affine
dimension $m$ on a complete intersection over an algebraic field extension $K$ of
$\mathbb{Q}$. The number of variables required to do this is no larger than what is known
for the analogous problem over $\mathbb{Q}$. As an application we show that any smooth
hypersurface over $K$ whose dimension is large enough in terms of the degree is
$K$-unirational, provided that either the degree is odd or $K$ is totally imaginary.

1. Introduction

One of the main developments of recent years in the study of the circle method
has been an increasing interest in generalising results that have been obtained over
the rationals to more general fields with an arithmetic structure such as number
fields or function fields, both in order to acquire a deeper understanding of how
specific the results are to the integers or integer-like objects, and in order to be
able to circumvent certain restrictions imposed by the integral setting. Some of the
major efforts in this direction are due to Skinner [26, 27] who established number
field versions of the influential papers by Heath-Brown on rational points on non-
singular cubic surfaces [14] and by Birch on forms in many variables [1]. The former
paper falls somewhat short of what had been known in the rational case, but in
recent work Browning and Vishe [8] found an improved treatment so that now the
number field case is almost as well understood as the rational case. Similarly, the
recent paper of Browning and Heath-Brown generalising Birch’s theorem to systems
involving differing degrees [7] has immediately been translated to the number field
setting by Frei and Madritsch [12], as has Dietmann’s work on small solutions of
quadratic forms [11] by Helfrich [16]. In this memoir we aim to continue in this
direction by providing a number field version of the author’s recent work on linear
spaces on hypersurfaces [2, 4].

Let $K$ be an algebraic number field of degree $n$ over $\mathbb{Q}$ with ring of integers $\mathcal{O}_K$.
Let $\omega_1, \ldots, \omega_n$ be an integral basis of $\mathcal{O}_K$, then it is also a $\mathbb{Q}$-basis of $K$. Consider
a box

$$
B = \{x \in K : x = \hat{x}_1 \omega_1 + \cdots + \hat{x}_n \omega_n, \quad \hat{x}_i \in [-1, 1]\}.
$$

For a given set of polynomials $F^{(1)}, \ldots, F^{(R)} \in K[x_1, \ldots, x_s]$ of degree $d$ we study
the number $N_m(P)$ of $m$-tuples $x_1, \ldots, x_m \in (\mathcal{O}_K \cap PB)^*$ satisfying the identities

$$
F^{(\rho)}(x_1 t_1 + \cdots + x_m t_m) = 0 \quad (1 \leq \rho \leq R)
$$

Key words and phrases. Forms in many variables, linear spaces, number fields.
identically in $t_1, \ldots, t_m$. Set $r = \binom{d-1+m}{d}$, and let

$$\text{Sing}^*(F) = \left\{ x \in \mathbb{A}^s_K : \text{rank} \left( \frac{\partial F^{(i)}(x)}{\partial x_i} \right)_{\rho, i} \leq R - 1 \right\}.$$  

As in comparable work, our methods are equally strong over number fields as they are over the rationals.

**Theorem 1.1.** Let $F^{(1)}, \ldots, F^{(R)}$ be as above, and suppose that $m$ and $d \geq 2$ are integers and that

$$s - \dim \text{Sing}^* F > 2^{d-1}(d - 1)Rr(R + 1). \quad (1.2)$$

Then there exists a non-negative constant $c$ and a parameter $\delta > 0$ such that

$$N_m(P) = c(P^n)^{ms-rd} + O((P^n)^{ms-rd-\delta}). \quad (1.3)$$

The constant $c$ has an interpretation as a product of local densities, so that Theorem 1.1 yields an analytic Hasse principle. We also note that the case $m = 1$ recovers Skinner’s result [26], and for larger $m$ we save approximately one factor $r$ over what a naive application of Skinner’s methods would yield, thus replicating the improvements of the author’s earlier work [2, 4] over a naive application of Birch’s theorem. One feature of the proof that is worth highlighting is our treatment of the singular integral. In recent work, Frei and Madritsch [12] identified an inaccuracy in the work of Skinner [27], and proposed a corrected treatment. Unfortunately, their argument is rather involved, but we are able to give a much simplified proof of the same statement that parallels the treatment over $\mathbb{Q}$.

As we will see in §5, this follows from Theorem 1.1 by applying results from the literature. Observe further that the first term in the maximum occurs for $d \leq 3$ and large $m$, whereas for $d \geq 4$ the second term always dominates.

A consequence of Theorem 1.2 concerns the question under what conditions a hypersurface is unirational. Two projective varieties are said to be birationally equivalent if they can be mapped onto one another by a rational map. Unfortunately, establishing birational equivalence for two given varieties is often difficult in practice, so for many applications one is satisfied with the weaker notion of unirational covers, which abandons the requirement that the rational map be an isomorphism on a Zariski-open subset and only requires a surjective cover. We call a projective variety $V$ unirational over $K$ if there exists a dominant morphism from the projective space $\mathbb{P}^{\dim V}_K$ onto $V$. It is straightforward to show that quadrics with a $K$-point are always unirational over their ground field, and in a series of papers by Segre [24], Manin [13, II.2], Colliot-Thélène, Sansuc and Swinnerton-Dyer [9, Remark 2.3.1] and Kollár [17, Theorem 1.1], it has been shown that a smooth rational cubic hypersurface of dimension at least 2 over any field $K$ is unirational over $K$ as soon as it contains a $K$-point.
For higher degrees the situation is more complicated. Following up on ideas by Morin \[19\] and Predonzan \[21\], Paranjape and Srinivas \[20\] were able to show that a general complete intersection of sufficiently low degree is always unirational over its ground field. This has been taken one step further by Harris, Mazur and Pandharipande \[13\], who improved upon the almost-all-result of the former authors by showing that every smooth hypersurface containing a sufficiently large \(K\)-rational linear space is unirational over \(K\). Stating their result requires some notation. For \(d \geq 2\) and \(k \geq 0\) set

\[
N(d, k) = \begin{cases} 
\frac{(k + 1)}{2} + 3 & \text{if } d = 2, \\
\left(\frac{N(d - 1, k) + d}{d - 1}\right) + N(d - 1, k) + \left(\frac{k + d}{d}\right) + 2 & \text{for } d \geq 3,
\end{cases}
\]

and

\[
L(d, k) = \begin{cases} 
0 & \text{if } d = 2, \\
N(d - 1, L(d - 1)) & \text{if } d \geq 3.
\end{cases}
\]

Then Corollary 3.7 of \[13\] shows that a hypersurface of degree \(d\) over \(K\) is unirational over \(K\) if it contains a \(K\)-rational plane of dimension \(m \geq L(d) + 1\). Hence as a consequence of Theorem \[1.2\] we obtain the following.

**Theorem 1.3.** Suppose that either \(K\) is a totally imaginary field extension or \(d\) is odd, and let \(F \in K[x_1, \ldots, x_s]\) be a non-singular homogeneous polynomial of degree \(d \geq 4\), where

\[
s > 2^{d-1}(d - 1)(d^2 + L(d) + 1)^{2d-2} d^{2d-1}.
\]

Then the hypersurface \(F(x) = 0\) is unirational over \(K\).

Unfortunately, the numbers required to achieve this are very large. In fact, one can compute \(L(4) = 97, L(5) = 252694544886958321667 \approx 2.52 \ldots \cdot 10^{20}\) and in general

\[
L(d) \approx d^{d \ldots d \text{ times}} = d \uparrow\uparrow d.
\]

Accordingly, the bounds of Theorem \[1.3\] are of size \(L(d)^{2d-2}\), which yields the bound \(s > 265650463309824 \approx 2.65 \ldots \cdot 10^{14}\) in the case \(d = 4\), and \(s > 1.62 \ldots \cdot 10^{173}\) for \(d = 5\). One should expect that by applying ideas due to Heath-Brown \[15\] and Zahid \[29\] significantly sharper estimates can be obtained for these small degrees; we intend to pursue such refinements in future work.

The author is grateful to Tim Browning for motivating this work and in particular for pointing out the application to unirationality.

2. Notation and Setting

Our setting over number fields demands a certain amount of notation. In our nomenclature we largely follow the works of Skinner \[27\] and Browning and Vishe \[8\]. Let \(n = n_1 + 2n_2\), where \(n_1\) and \(n_2\) denote the number of real resp. complex embeddings of \(K\). We denote these embeddings by \(\eta_i\) with the convention that real embeddings are labelled with indices \(1 \leq i \leq n_1\), and for \(1 \leq i \leq n_2\) the embeddings
with indices \( n_1 + i \) and \( n_1 + n_2 + i \) are conjugates. Most of the time we will work over the \( n \)-dimensional \( \mathbb{R} \)-algebra

\[
\mathbb{V} = K \otimes_{\mathbb{Q}} \mathbb{R} \cong \bigoplus_{l=1}^{n_1+n_2} K_l,
\]

where \( K_l \) is the completion of \( K \) with respect to \( \eta_l \), so we have \( K_l = \mathbb{R} \) for \( 1 \leq l \leq n_1 \) and \( K_l = \mathbb{C} \) for \( n_1 + 1 \leq l \leq n_2 \). Of course, \( K \) has a canonical embedding in \( \mathbb{V} \) given by

\[
\alpha \mapsto (\eta_1(\alpha), \ldots, \eta_{n_1+n_2}(\alpha)),
\]

which allows us to identify \( K \) with its image in \( \mathbb{V} \). By writing \( \alpha^{(i)} = \eta_i(\alpha) \) we thus have \( v = \oplus_l v^{(l)} \) for each \( v \in \mathbb{V} \). The norm and trace on \( \mathbb{V} \) are defined via

\[
\text{Nm}(v) = v^{(1)} \cdots v^{(n_1)} |v|_{V^{(n_1+1)}} \cdots |v|_{V^{(n_1+n_2)}},
\]

\[
\text{Tr}(v) = v^{(1)} + \cdots + v^{(n_1)} + 2 R v^{(n_1+1)} + \cdots + 2 R v^{(n_1+n_2)}.
\]

Write further \( \Omega(K) \) for the set of places of \( K \), and let \( \Omega_0(K) \) and \( \Omega_\infty(K) \) denote the set of finite and infinite places, respectively.

The image of any fractional ideal of \( \mathcal{O}_K \) takes the shape of a lattice in \( \mathbb{V} \) as follows. If \( \{\omega_1, \ldots, \omega_n\} \) forms a \( \mathbb{Z} \)-basis of \( \mathcal{O}_K \), then it is also an \( \mathbb{R} \)-basis of \( \mathbb{V} \) and we have

\[
\mathbb{V} = \{ x = \hat{x}_1 \omega_1 + \cdots + \hat{x}_n \omega_n : \hat{x}_i \in \mathbb{R} \text{ for all } 1 \leq i \leq n \}. \tag{2.1}
\]

We further write

\[
\mathcal{O}_K^+ = \{ x = \hat{x}_1 \omega_1 + \cdots + \hat{x}_n \omega_n \in \mathcal{O}_K : \hat{x}_i \geq 0 \text{ for all } 1 \leq i \leq n \}.
\]

In the interest of maintaining a consistent notation, we will denote elements in \( K \) by lower case letters, and denote the respective vector in \( \mathbb{R}^n \) by hats, so that for \( x \in K \) we have

\[
x = \bigoplus_{l=1}^{n_1+n_2} x^{(l)} = \hat{x}_1 \omega_1 + \cdots + \hat{x}_n \omega_n, \quad \hat{x} = (\hat{x}_1, \ldots, \hat{x}_n).
\]

The analogue of the unit interval for the field \( K \) is given by the set

\[
\mathbb{T} = \{ x \in \mathbb{V} : 0 \leq \hat{x}_i \leq 1 \quad (1 \leq i \leq n) \}.
\]

We use the volume form induced by (2.1), namely \( dx = d\hat{x}_1 \cdots d\hat{x}_n \). According to this volume form, we have \( \text{vol}(\mathbb{T}) = 1 \) as expected. For any element \( a \in K \) we have the denominator ideal

\[
q(a) = \{ b \in \mathcal{O}_K : ab \in \mathcal{O}_K \}, \tag{2.2}
\]

which is easily extended to vectors \( a \in K^n \) by setting \( q(a) = \bigcap_i q(a_i) \). Denominator ideals are always principal, and we have

\[
\text{Card}\{ \gamma \in (\mathbb{T} \cap K)^R : |\text{Nm}(\gamma)| = q \} \ll q^{R+\varepsilon} \tag{2.3}
\]

(see e.g. [27, Lemma 5 (i)]).

In the embedding (2.1) we have the standard height function

\[
|x| = \max(\{ |\hat{x}_1|, \ldots, |\hat{x}_n| \}),
\]

so that \( |x| \asymp \max_{v \in \Omega_\infty(K)} |x|_v \). This norm extends in the obvious manner to vectors \( x \in \mathbb{V}^* \). Furthermore, for \( x \in K \) we have \( |x^{-1}| \ll |x|^{n-1}/|\text{Nm}x| \).
If $F \in \mathbb{V}[x_1, \ldots, x_s]$ is a polynomial, we may consider the associated polynomial
\[
\hat{F}(\vec{x}) = \text{Tr}(F(x)) \in \mathbb{R}[\hat{x}_{1,1}, \ldots, \hat{x}_{s,n}].
\]
Projecting on the basis vectors $\omega_l$, we also have the system
\[
\hat{F}_l(\vec{x}) = \text{Tr}(\omega_l F(x)) \in \mathbb{R}[\hat{x}_{1,1}, \ldots, \hat{x}_{s,n}] \quad (1 \leq l \leq n).
\]
Since we may assume the basis $\{\omega_1, \ldots, \omega_n\}$ to be orthonormal, this isolates the $l$-th coefficient of $F(x)$ with respect to the representation $(2.4)$
\[
\Phi_l = \{e_l(x) \mid 1 \leq l \leq n\}
\]
where $e_l(x)$ is the $l$-th basis vector for suitable combinatorial constants $A(j)$. Set
\[
\Phi_j^{(\rho)}(x_1, \ldots, x_m) = A(j)\Phi_j^{(\rho)}(x_{j_1}, x_{j_2}, \ldots, x_{j_d}), \quad (1 \leq \rho \leq \rho, j \in J).
\]
We write $\mathbf{x} = (x_1, \ldots, x_m) \in \mathbb{V}^{ms}$. It follows by expanding the system $(1.1)$ as in $(2.4)$ that counting solutions $x_1, \ldots, x_m$ to $(1.1)$ is equivalent to counting solutions $\mathbf{x}$ to the system
\[
\Phi_j^{(\rho)}(\mathbf{x}) = 0 \quad (1 \leq \rho \leq \rho, j \in J).
\]
We write $\alpha^{(\rho)} = (\alpha_j^{(\rho)})_{j \in J}$ and $\alpha = (\alpha^{(1)}, \ldots, \alpha^{(R)})$. For the sake of completeness we also define $\alpha_j = (\alpha_j^{(1)}, \ldots, \alpha_j^{(R)})$. In this notation we have
\[
N_m(P) = \sum_{\mathbf{x} \in PB^{sm}} \int_{\mathbb{T}^{2R}} e \left( \sum_{j \in J} \sum_{\rho = 1}^{\rho} \alpha_j^{(\rho)} \Phi_j^{(\rho)}(\mathbf{x}) \right) \, d\alpha.
\]
It will be convenient to write
\[
\tilde{g}(\mathbf{x}; \alpha) = \sum_{j \in J} \sum_{\rho = 1}^{\rho} \alpha_j^{(\rho)} \Phi_j^{(\rho)}(\mathbf{x})
\]
and
\[
T_P(\alpha) = \sum_{\mathbf{x} \in PB^{sm}} e(\tilde{g}(\mathbf{x}; \alpha)),
\]
so that
\[
N_m(P) = \int_{\mathbb{T}^{2R}} T_P(\alpha) \, d\alpha.
\]
We remark that these definitions can be brought back to $\mathbb{R}$. In fact, writing
\[
\tilde{g}(\mathbf{x}; \alpha) = \sum_{l = 1}^{n} \sum_{j \in J} \sum_{\rho = 1}^{\rho} \alpha_j^{(\rho)} \Phi_j^{(\rho)}(\mathbf{x}),
\]
where $\alpha$ denotes the coefficient vector of $\alpha$ according to $(2.1)$, we obtain
\[
T_P(\alpha) = \sum_{\mathbf{x} \in \mathbb{Z}^{mns}} e \left( \tilde{g}(\mathbf{x}; \alpha) \right).
\]
Finally, we make some remarks as to the general notational conventions we shall adopt. Any statement involving the letter $\varepsilon$ is claimed to hold for any $\varepsilon > 0$. Consequently, the exact ‘value’ of $\varepsilon$ will not be tracked and may change from one expression to the next. The letter $P$ is always used to denote a large integer. Since many of our estimates are measured in terms of $P^n$, we set this quantity equal to $\Pi$. Expressions like $\sum_{n=1}^{x} f(n)$, where $x$ may or may not be an integer, should be read as $\sum_{1 \leq n \leq x} f(n)$. We will abuse vector notation extensively. In particular, equalities and inequalities of vectors should always be interpreted componentwise. Similarly, for $\mathbf{a} \in \mathbb{Z}^t$ we will write $(\mathbf{a}, b) = \gcd(a_1, \ldots, a_t, b)$. Finally, the Landau and Vinogradov symbols will be used in their established meanings, and the implied constants are allowed to depend on $s$, $m$, $d$ and $n$ as well as the coefficients of $F$, but never on $P$.

3. Exponential Sums

In this section we study the exponential sum $T_P(\hat{\alpha})$ in greater detail. We define the discrete differencing operator $\Delta_{i,\mathbf{h}}$ via its action

$$\Delta_{i,\mathbf{h}} \mathfrak{F}(\mathbf{x}; \hat{\alpha}) = \mathfrak{F}(\mathbf{x}_1, \ldots, \mathbf{x}_i + \mathbf{h}, \ldots, \mathbf{x}_m; \hat{\alpha}) - \mathfrak{F}(\mathbf{x}; \hat{\alpha}).$$

The following lemma is now a straightforward modification of [2, Lemma 3.1].

**Lemma 3.1.** Let $1 \leq k \leq d$. For $1 \leq i \leq k$ let $j_i$ be integers with $1 \leq j_i \leq m$. Then

$$|T_P(\alpha)|^{2^k} \ll P((2^{k-1}-1)m-k)^{ns} \sum_{\mathbf{h}_1, \ldots, \mathbf{h}_k \in P\mathbb{B}^s} \sum_{\mathbf{x}} e(\Delta_{j_1,\mathbf{h}_1} \cdots \Delta_{j_k,\mathbf{h}_k} \mathfrak{F}(\mathbf{x}; \hat{\alpha})), $$

where the sum over $\mathbf{x}$ is over a suitable box contained in $P\mathbb{B}^{sm}$.

Observe that in each differencing step the degree of the forms involved decreases by one, so after $d - 1$ steps we arrive at a polynomial that is linear in $\mathbf{x}$. For the sake of simplicity we write $\mathcal{H}$ for the $(d-1)$-tuple $(\mathbf{h}_1, \ldots, \mathbf{h}_{d-1})$. In this notation we have

$$|T_P(\alpha)|^{2^{d-1}} \ll P((2^{d-1}-1)m-(d-1))^{ns} \sum_{\mathcal{H}} \sum_{\mathbf{x}} e(\Delta_{j_1,\mathbf{h}_1} \cdots \Delta_{j_{d-1},\mathbf{h}_{d-1}} \mathfrak{F}(\mathbf{x}; \hat{\alpha}))
\ll P(2^{d-1}m-d)^{ns} \sum_{\mathcal{H}} \left| \sum_{\mathbf{x}_{j_{d}}} e(\sum_{\rho=1}^{R} \alpha_{j}^{(\rho)} \Phi_{(\rho)}(\mathbf{x}_{j_{d}}, \mathcal{H})) \right|,$$

where $M(j)$ is a suitable combinatorial constant as in [2, Lemma 3.2].

We write $\hat{\mathcal{H}}$ for the coefficient vector of $\mathcal{H}$ by the representation (2.1) and define the functions $\hat{B}_{i,l}^{(\rho)} \in \mathbb{Z}[\hat{\mathbf{h}}_1, \ldots, \hat{\mathbf{h}}_{d-1}]$ via the identity

$$\hat{\Phi}^{(\rho)}(\hat{\mathbf{x}}, \hat{\mathcal{H}}) = \sum_{i=1}^{s} \sum_{l=1}^{n} \hat{x}_{i,l} \hat{B}_{i,l}^{(\rho)}(\hat{\mathcal{H}}).$$
In this notation the above inequality can be brought back to \( \mathbb{R} \), where it reads
\[
|T_P(\alpha)|^{2d-1} \ll P^{(2d-1)m-d} \sum_{\hat{H}} \prod_{i=1}^{s} \prod_{t=1}^{n} e \left( M(j) \sum_{\rho=1}^{R} \hat{\alpha}_{j,l}^{(\rho)} \hat{B}_{i,l}^{(\rho)}(\hat{H}) \right) 
\ll P^{(2d-1)m-d} \sum_{\hat{H}} \prod_{i=1}^{s} \prod_{t=1}^{n} \min \left\{ P, \left| M(j) \sum_{\rho=1}^{R} \hat{\alpha}_{j,l}^{(\rho)} \hat{B}_{i,l}^{(\rho)}(\hat{H}) \right|^{-1} \right\}.
\]

Denote by \( N_j(A, B) \) the number of \((d-1)\)-tuples \((\hat{h}_1, \ldots, \hat{h}_{d-1}) \in \mathbb{Z}^{ns} \) with \(|\hat{h}_k| \leq A\) satisfying
\[
\left| M(j) \sum_{\rho=1}^{R} \hat{\alpha}_{j,l}^{(\rho)} \hat{B}_{i,l}^{(\rho)}(\hat{H}) \right| < B \quad (1 \leq l \leq n, 1 \leq i \leq s).
\]

The argument of the proof of Lemma 3.2 of \cite{4} shows then that
\[
\sum_{\hat{H}} \prod_{i=1}^{s} \prod_{t=1}^{n} \min \left\{ P, \left| M(j) \sum_{\rho=1}^{R} \hat{\alpha}_{j,l}^{(\rho)} \hat{B}_{i,l}^{(\rho)}(\hat{H}) \right|^{-1} \right\} \ll P^{ns+\varepsilon} N_j(P, P),
\]
so it suffices to understand \( N_j(P, P) \). This is an integral lattice problem and can be treated by the usual methods.

**Lemma 3.2.** Suppose that \( k > 0 \) and \( \theta \in [0, 1) \) are parameters and that for some \( \alpha \in \mathbb{T}^{R\nu} \) one has
\[
|T_P(\alpha)| \gg \Pi^{ns-k\theta}.
\]

Then for any \( j \in J \) we have
\[
N_j(P^{\theta}, P^{d-(d-1)\theta}) \gg (\Pi^{\theta})^{(d-1)s-2^{d-1}k}.
\]

**Proof.** This follows from the argument leading to \cite[Lemma 3.3]{2}. By applying standard results from the geometry of numbers \cite[Lemma 12.6]{10} as in the proof of Lemma 3.4 of \cite{4}, it follows that
\[
N_j(P^{\theta}, P^{d-(d-1)\theta}) \gg P^{-(d-1)(1-\theta)ns} N_j(P, P),
\]
so we find
\[
|T_P(\alpha)|^{2d-1} \ll P^{(2d-1)m-d} P^{ns+\varepsilon} P^{d-(d-1)\theta} N_j(P^{\theta}, P^{d-(d-1)\theta}).
\]

Under the hypotheses of the lemma we have \(|T_P(\alpha)|^{2d-1} \gg P^{2^{d-1}(ns-k\theta)}\), and rearranging reproduces the claim. \( \square \)

We may now apply the argument of \cite[Lemma 2]{27} to each \( \alpha_j \) in turn. This is analogous to the procedure of \cite[Lemma 3.4]{2}, and as a result we find that, if the exponential sum is large at some value \( \alpha \), then either all components of \( \alpha \) have a good approximation in the \( \mathbb{K} \)-rational numbers, or else the system of forms \( F^{(1)}, \ldots, F^{(R)} \) is singular in the sense that the matrix \((B_{i,l}^{(\rho)}(\hat{H})_{i,l,p})\) has rank less than \( R \) for at least \((\Pi^{\theta})^{(d-1)s-2^{d-1}k-\varepsilon}\) values of \( \hat{H} \in P^{\theta} B^{(d-1)s} \). Furthermore, the proof of Lemma 4 in \cite{27} now carries over unchanged, so if \( s - \dim \text{Sing}^* F > 2^{d-1}k \), then the singular case is excluded. This yields the following tripartite case distinction.
Lemma 3.3. Let $0 < \theta \leq 1$ and $k > 0$ be parameters, and suppose that
\[ s - \dim \text{Sing}^* F > 2^{d-1}k. \]  
(3.1)

Then for each $\alpha \in \mathbb{T}^R$ either
(A) the exponential sum $T_P(\alpha)$ is bounded by
\[ |T_P(\alpha)| \ll \Pi^{ms-k\theta}, \]
or
(B) for every $j \in J$ one finds $(q_j, a_j) \in (C^+_K)^{R+1}$ satisfying
\[ 1 \leq |q_j| \ll P^{(d-1)R^\theta} \quad \text{and} \quad |a_i q_j - a_j| \ll P^{-d+(d-1)R^\theta}. \]

This result lies at the heart of our analysis in the next section.

4. APPLICATION OF THE CIRCLE METHOD

For a suitable parameter $c_1$ write
\[ \mathcal{M}_{q,a}(P, \theta) = \{ \alpha \in \mathbb{T}^R : |\alpha^{(\rho)} q - a^{(\rho)}| \leq c_1 P^{-d+R(d-1)^\theta} \quad (1 \leq \rho \leq R) \}, \]
and
\[ \mathcal{M}^*_{q,a}(\theta) = \bigcup_{q \in [\alpha^{(\rho)}]_0} \bigcup_{(q_j, a_j) \in (C^+_K)^{R+1}} \bigcup_{\alpha \in \mathcal{M}_{q,a}(P, \theta)}. \]

We further set $\mathcal{M}_P(\theta) = (\mathcal{M}^*_{q,a}(\theta))^\circ$ and $m_P(\theta) = \mathbb{T}^R \setminus \mathcal{M}_P(\theta)$. Note that the constant $c_1$ can be chosen in such a manner that the major arcs dissection reflects the case distinction of Lemma 3.3.

Now suppose that some $\alpha \in \mathcal{M}_P(\theta)$ has two distinct approximations, then for some $j \in J$ and $1 \leq \rho \leq R$ there exist two pairs of $\mathbb{K}$-integers $(a_1, q_1)$ and $(a_2, q_2)$ with the property that $|q_1| \ll P^{R(d-1)^\theta}$ and $|a_i - \alpha^{(\rho)}_j q_i| \ll P^{-d+(d-1)R^\theta}$ for $i \in \{1, 2\}$.

Hence we have the chain of inequalities
\[ 1 \ll |a_1 q_2 - a_2 q_2| \ll |q_2| |a_1 - \alpha^{(\rho)}_j q_1| + |q_1| |a_2 - \alpha^{(\rho)}_j q_2| \ll P^{-d+2R(d-1)^\theta}. \]

Thus if
\[ 2R(d-1)^\theta < d, \]
then the major arcs are disjoint.

By Lemma 5 (iii) of [27] we have
\[ \text{vol} \mathcal{M}^*_P(\theta) \ll \Pi^{-Rd+R(R+1)(d-1)^\theta+\varepsilon}, \]
and hence
\[ \text{vol} \mathcal{M}_P(\theta) \ll \Pi^{-Rd+R(R+1)r(d-1)^\theta+\varepsilon}. \]

It is then clear that Lemma 4.1 of [2] can be directly transferred to the number field setting.

Lemma 4.1. Suppose that (3.1) holds and that the parameters $k$ and $\theta$ satisfy
\[ 0 < \theta < \theta_0 = \frac{d}{(d-1)(R+1)} \]
and

\[ k > Rr(R + 1)(d - 1). \]  \tag{4.2}

Then there exists a \( \delta > 0 \) such that the minor arcs contribution is bounded by

\[ \int_{m_P(\theta)} |T_P(\alpha)| \, d\alpha \ll \Pi^{ms - Rrd - \delta}. \]

We now define a second set of major arcs that will be easier to work with. Recall that Lemma 3.3 produces an approximation \( \alpha_j = a_j/q_j + \beta_j \) for each \( j \in J \) in turn. Taking least common multiples, we find that there is an approximation \( \alpha = a/q + \beta \) with \( \|q\| \leq \prod_j |q_j| \ll P^{Rr(d-1)\theta} \) and \( \|q\beta\| \ll P^{-d + Rr(d-1)\theta} \). Recall the definition (2.2), and for \( \gamma \in (K \cap T)^{Rr} \) set \( q_2 = |Nm(q(\gamma))| \). In this notation we denote the homogeneous major arcs by

\[ N_2 = \{ \alpha \in T^{Rr} : |\alpha_j - \gamma_j| \leq c_2 P^{-d + Rr(d-1)\theta} \} \]

and

\[ \mathcal{M}(\theta) = \bigcup_{\gamma \in (K \cap T)^{Rr}, \ q_2 \leq c_2 P^{Rr(d-1)\theta}} N_2. \]

It follows from [27, Lemma 5 (ii)] that \( c_2 \) can be chosen in such a way that \( \mathcal{M}_P(\theta) \subseteq \mathcal{M}(\theta) \). We further let

\[ S(\gamma) = \sum_{x \pmod{q(\gamma)}} e(\tilde{f}(x; \gamma)), \]

\[ v_P(\beta) = \int_{PB^{sm}} e(\tilde{f}(y; \beta)) \, dy, \]

and set

\[ \mathcal{S}(P) = \sum_{\gamma \in (K \cap T)^{Rr}, \ q_2 \leq c_2 P^{Rr(d-1)\theta}} q_2^{-ms} S(\gamma), \]

\[ \mathcal{F}(P) = \int_{|\beta| \leq c_2 P^{-d + Rr(d-1)\theta}} v_P(\beta) \, d\beta. \]

In this notation the exponential sum can be approximated by a product of the truncated singular series and integral.

**Lemma 4.2.** Let \( \alpha \in T^{Rr} \) be of the shape \( \alpha = \gamma + \beta \) with \( \gamma \in (K \cap T)^{Rr} \). Then we have

\[ \left| T_P(\alpha) - q_2^{-ms} S(\gamma) v_P(\beta) \right| \ll q_2 P^{ms-1} \left( 1 + P^d \sum_{\rho=1}^{R} \sum_{j \in J} |\beta_j(\rho)| \right). \]

**Proof.** This is [12, Lemma 5.2] specified to our situation. \( \square \)
We can now integrate over the major arcs $\mathcal{R}(\theta)$. Their volume is easily computed using the fact that $\text{vol} \mathcal{R}(\theta) \ll \left(P^{-d+(d-1)nR\theta}R\right)^n$. Thus, using (2.3), we have

$$\text{vol} \mathcal{R}(\theta) \ll \sum_{q=1}^{c_2 P^{Rr(d-1)n\theta}} \sum_{\gamma \in (\mathbb{K} \cap \mathbb{T})^{Rr}} \text{vol} \mathcal{R}(\theta) \ll P^{-nRrd+((n+1)Rr+1)Rr(d-1)n\theta+\varepsilon}. $$

It follows that

$$\int_{\mathcal{R}(\theta)} |T_P(\alpha)| \, d\alpha - \mathcal{G}(P) \mathcal{J}(P) \ll \text{vol} \mathcal{R}(\theta) \sup_{\alpha = 1, \beta \in \mathcal{R}(\theta)} |T_P(\alpha) - q^{-ms} S(\gamma) v_P(\beta)| \ll P^{-nRrd+((n+1)Rr+3)Rr(d-1)n\theta+\varepsilon}. $$

It is clear that this is dominated by $\prod_{Q}^{ms-Rrd-\delta}$ for some $\delta > 0$ whenever $\theta$ has been chosen small enough. Furthermore, a standard rescaling shows that

$$v_P(\beta) = \prod_{Q}^{ms} v_1(P^{d\beta}), \quad (4.3)$$

and therefore

$$\mathcal{J}(P) = \prod_{Q}^{ms-Rrd} \int_{[\beta] \in c_2 P^{Rr(d-1)n\theta}} v_1(\beta) \, d\beta. $$

It thus remains to see that the limits $\mathcal{G} = \lim_{P \to \infty} \mathcal{G}(P)$ of the singular series and $\mathcal{J} = \lim_{P \to \infty} \prod_{Q}^{ms+Rrd} \mathcal{J}(P)$ of the rescaled singular integral exist.

**Lemma 4.3.** Let $k$ be as in Lemma 3.3. For any $\gamma \in (\mathbb{T} \cap \mathbb{K})^{Rr}$ we have

$$q_2^{-ms} |S(\gamma)| \ll q_2^{-\frac{k}{n(d-1)}}. \quad (4.4)$$

**Proof.** Here we follow the treatment of [5, Lemma 4.1 resp. 7.1], which is in turn a simplification of [7, Lemma 8.2]. From combining Lemma 4.2 with (4.3) and observing that $v_1(\beta) \asymp 1$, it follows that the relation

$$q_2^{-ms} |S(\gamma)| \ll Q^{-ms} |T_Q(\gamma)| + Q^{-1} q_2^{-\frac{k}{n(d-1)}} \quad (4.4)$$

holds for any parameter $Q$. We set $Q = q_2^A$ for some suitably large parameter $A$. Take $q \in q(\gamma) \setminus \{0\}$ such that $|q|$ is minimal, then it follows from Minkowski’s Theorem that $q_2 \gg |q|^n$. Fix $\theta$ such that $|q| = c_1 Q^{d-1} R^\theta$, so that $\gamma \in \mathcal{R}_Q(\theta)$. Observe further that by taking $A$ large enough we may assume that (4.1) is satisfied, so the major arcs are disjoint and $\gamma$ lies just on the edge of the major arcs $\mathcal{M}_Q(\theta)$. By continuity, the minor arcs bound for $T_Q(\gamma)$ is still applicable on the boundary of the minor arcs, and we find from Lemma 3.3 (A) that

$$Q^{-ms} |T_Q(\gamma)| \ll Q^{-nk\theta} \ll |q_2|^{-\frac{k}{n(d-1)}}. $$

The proof is now complete upon inserting this bound into (4.4) and choosing $A$ sufficiently large.

With the help of Lemma 4.3 we can show that the singular series converges. In fact, by (2.3) we have

$$\mathcal{G} = \sum_{\gamma \in (\mathbb{K} \cap \mathbb{T})^{Rr}} q_2^{-ms} S(\gamma) \ll \sum_{q=1}^{\infty} q^{-\frac{k}{n(d-1)}} \sum_{\gamma \in (\mathbb{K} \cap \mathbb{T})^{Rr}} q_2^{-q} \ll \sum_{q=1}^{\infty} q^{Rr-\frac{k}{n(d-1)+\varepsilon}},$$
and this sum converges whenever
\[ k > R(d - 1)(Rr + 1). \]  

We now turn to the completion of the singular integral.

**Lemma 4.4.** For any \( \beta \in \mathbb{V}^R \) we have
\[ |v_1(\beta)| \ll (1 + |\beta|)^{-\frac{nk}{(d-1)Rr}}. \]

**Proof.** This is similar to the previous lemma. Observe that the statement is trivial for \( |\beta| \leq 1 \), so we may assume \( |\beta| > 1 \) for the remainder of the argument. By taking \( a = 0 \) and \( q = 1 \), Lemma 4.2 together with (4.3) show for any \( Q \) that
\[ |v_1(\beta)| = Q^{-mns}|v_Q(Q^{-d}\beta)| \ll Q^{-mns}|T_Q(Q^{-d}\beta)| + Q^{-1}|\beta|, \]
where we used that \( S(0) = 1 \). We now set \( Q = |\beta|^A \) for some suitably large parameter \( A \) and determine \( \theta \) such that
\[ |\beta| = c_1 Q^{(d-1)R\theta}, \]
so that \( P^{-d}\beta \in \mathbb{M}_Q(\theta) \) with approximation \( a = 0 \) and \( q = 1 \). Furthermore, by choosing \( A \) large enough we can enforce (4.1), so we may assume the major arcs to be disjoint. As in the previous lemma, this implies that the point \( Q^{-d}\beta \) lies just on the edge of the major arcs in a region where the minor arcs bound of Lemma 3.3 is still valid. This leads to the complementary bound
\[ Q^{-mns}|T_Q(Q^{-d}\beta)| \ll Q^{-nk\theta} \ll |\beta|^{-\frac{nk}{(d-1)Rr}}. \]

On inserting this into (4.6), we see that
\[ |v_1(\beta)| \ll |\beta|^{-\frac{nk}{(d-1)Rr}} + Q^{-1}|\beta| = |\beta|^{-\frac{nk}{(d-1)Rr}} + |\beta|^{1-A}, \]
which is satisfactory whenever \( A \) has been chosen large enough.

As in the case of the singular series, we can now complete the singular integral. We have
\[ \int_{|\beta| \leq X} v_1(\beta) \, d\beta \ll \int_{|\beta| \leq X} (1 + |\beta|)^{-\frac{nk}{(d-1)Rr}} \, d\beta \ll 1 + X^{n(Rr - \frac{nk}{(d-1)Rr})}, \]
from whence it follows that the limit \( X \to \infty \) exists as soon as (4.5) holds. Finally, we take note that (4.5) is strictly implied by (4.2). This proves Theorem 1.1.

5. **The Local Factors**

It is a consequence of the Chinese Remainder Theorem that we have the product representation
\[ \mathcal{G} = \prod_{p \leq \mathcal{O}_K \text{ prime}} \chi_p, \]
where
\[ \chi_p = \sum_{j=0}^{\infty} \sum_{\gamma \in (\mathbb{K} \cap T)^R \at \gamma(p)} |Nm p|^{-jms} S(\gamma). \]
Furthermore, a straightforward modification of standard arguments as in [10, Chapter 5] shows that this product converges, and furthermore that the factors can be rewritten as

\[
\chi_p = \lim_{j \to \infty} \vert N_{\mathbb{Q}} p \vert^{-jms} \sum_{\mathfrak{m} (\text{mod } p^j)^{R_{\rho}}} \sum_{\mathfrak{m} \leq \mathfrak{m}(\gamma)} e(\mathfrak{m}(\mathfrak{m}, \gamma))
\]

\[
= \lim_{j \to \infty} \vert N_{\mathbb{Q}} p \vert^{j(R_{\rho} - ms)} \Gamma(p^j),
\]

where

\[
\Gamma(p^j) = \text{Card}\{\mathfrak{m} (\text{mod } p^j) : \Phi_j^{(\rho)}(\mathfrak{m}) \in p^j \ (1 \leq \rho \leq R, j \in J)\}.
\]

Let \( v = v(p) \) denote the place associated to the prime ideal \( p \), then we will equivalently write \( \chi_p = \chi_{v(p)} \). For \( v \in \Omega_0(\mathbb{K}) \) let \( \gamma^{(v)}_{\mathbb{K}}(R, m, d) \) denote the smallest integer \( \gamma \) such that any system of \( R \) forms of degree \( d \) over \( \mathbb{K} \) contains an \( m \)-dimensional linear subspace in \( \mathbb{K}_v \), and write \( \gamma^{(0)}_{\mathbb{K}}(R, m, d) = \max_{v \in \Omega_0(\mathbb{K})} \gamma^{(v)}_{\mathbb{K}}(R, m, d) \). Then we have a lower bound for bound for \( \Gamma(p^j) \) which suffices to show that the local factor \( \chi_p \) is positive.

**Lemma 5.1.** We have

\[
\Gamma(p^j) \gg \vert N_{\mathbb{Q}} p \vert^{j(ms - \gamma^{(0)}_{\mathbb{K}}(R, m, d))},
\]

and thus \( \chi_p \gg 1 \) whenever

\[
k > (d - 1)R_{\gamma^{(0)}_{\mathbb{K}}}(R, m, d).
\]

Here \( k \) is the parameter of Lemma 3.3.

**Proof.** The first statement is an adaptation of Schmidt [22, Lemma 2] (see also [3, Lemma 4.4]). The proof uses a combinatorial argument involving cyclic subgroups of the additive group \((\mathcal{O}_{\mathbb{K}}/p^j)^{ms}\), which carries over to number fields without difficulties. The second statement is easily obtained by adapting the arguments of [22, §7].

The quantity \( \gamma^{(0)}_{\mathbb{K}}(R, m, d) \) can be bounded by results from the literature. For instance, Wooley [28, Theorem 2.4] shows that

\[
\gamma^{(0)}_{\mathbb{K}}(R, m, d) \leq (R^2d^2 + mR)^{2d-2}d^{d-1}
\]

for all algebraic number fields \( \mathbb{K} \).

We also record an alternative bound of a more geometric flavour. Define the singular locus of the expanded system (2.5) as

\[
\text{Sing}_{ms} F = \text{Sing} \Phi \subset A_{\mathcal{O}_{\mathbb{K}}}^{ms}.
\]

In this notation [3, Theorem 5.1] shows that \( \Gamma(p^j) \gg \vert N_{\mathbb{Q}} p \vert^{j(ms - R_{\rho})} \), and hence \( \chi_p \gg 1 \), as soon as

\[
ms - \dim \text{Sing}_{ms} F \geq \gamma^{(p)}_{\mathbb{K}}(R, m, d).
\]

The proof rests only on Hensel’s Lemma and a geometric argument, both of which carry over to the number field setting unchanged.
It remains to consider the singular integral
\[ \chi_{\infty} = \int_{V_{R}} v_{1}(\beta) \, d\beta. \]
As in [20, §6], we observe that \( v_{1}(\beta) \) factorises as a product over the infinite places of \( K \). Recall the notation \( x^{(l)} \) for the projection of \( x \) onto \( K_{l} \), then we have
\[ v_{1}(\beta) = \prod_{l=1}^{n_{1}+n_{2}} v_{1}^{(l)}(\beta^{(l)}), \]
where the factors are given by
\[ v_{1}^{(l)}(\beta^{(l)}) = \int_{[-1,1]^{2ms}} e\left(\overline{F^{(l)}(x^{(l)}; \beta^{(l)})}\right) \, d\overline{x}^{(l)} \]
in the case \( 1 \leq l \leq n_{1} \) when \( K_{l} \) is real, and
\[ v_{1}^{(l)}(\beta^{(l)}) = \int_{[-1,1]^{2ms}} e\left(2\Re F^{(l)}(x^{(l)}; \beta^{(l)})\right) \, d\Re x^{(l)} \, d\Im x^{(l)} \]
at the complex places \( n_{1} + 1 \leq l \leq n_{1} + n_{2} \). Correspondingly, we find
\[ \chi_{\infty} = \int_{V_{R}} \prod_{l=1}^{n_{1}+n_{2}} v_{1}^{(l)}(\beta^{(l)}) \, d\beta = \prod_{l=1}^{n_{1}+n_{2}} \int_{K_{l}} v_{1}^{(l)}(\beta^{(l)}) \, d\beta^{(l)} = \prod_{v \in \Omega_{\infty}(K)} \chi_{v}. \]
It remains to investigate under what conditions these factors are positive. For \( v \in \Omega_{\infty}(K) \) we define
\[ M_{v} = \{ \overline{x} \in A_{R, v}^{ms} : \eta_{v}(\Phi^{(\rho)}_{j})(\overline{x}) = 0 \quad (1 \leq \rho \leq R, j \in J) \}. \]
Then the methods of Schmidt [22, 23] apply.

**Lemma 5.2.** Suppose that (4.5) is satisfied. We have \( \chi_{v} \gg 1 \) whenever \( \dim M_{v} \geq ms - Rr \). In particular, this is the case whenever the manifold in question contains a non-singular point. It is always satisfied when \( d \) is odd or \( K_{v} = \mathbb{C} \).

**Proof.** In the case \( K_{v} = \mathbb{R} \), the first statement is due to Schmidt [23, Lemma 2 and §11] (see also [3, Chapter 4.5]), but the proof can be adapted without difficulties to the complex case as well. In order to simplify notation we will suppress the dependence on the embedding \( v \). For \( L > 0 \) set
\[ \hat{w}_{L}(x) = \max\{0, L(1 - L|x|)\} \quad (x \in \mathbb{R}), \]
\[ w_{L}(z) = \hat{w}_{L}(\Re z) \hat{w}_{L}(\Im z) \quad (z \in \mathbb{C}), \]
and define
\[ \mathcal{J}_{L} = \int_{[-1,1]^{2ms}} \prod_{\rho=1}^{R} \prod_{j \in J} w_{L}(\Phi^{(\rho)}_{j}(\overline{x})) \, d\Re \overline{x} \, d\Im \overline{x}. \]
The proof of [23, Lemma 2] (see also [3, Lemma 4.7]) can now be adapted in a straightforward manner by interpreting \( \mathcal{C} \) as a two-dimensional \( \mathbb{R} \)-vector space. This shows that under the hypothesis of the statement we have \( \mathcal{J}_{L} \gg 1 \) uniformly in \( L \).
In order to show that \( J_L \to J \) as \( L \) tends to infinity, we follow the argument of [23, §11] (see also [3, Lemma 4.6]) by considering real and imaginary parts separately. Since
\[
\hat{w}_L(x) = \int_{\mathbb{R}} e(\beta x) \left( \frac{\sin(\pi\beta/L)}{\pi\beta/L} \right)^2 d\beta
\]
and furthermore \( \hat{w}_L(x) = \hat{w}_L(-x) \), it is easy to show that
\[
w_L(z) = \int_{\mathbb{C}} e(\text{Tr} z\beta) \prod_{i=1,2} \left( \frac{\sin(\pi\beta_i/L)}{\pi\beta_i/L} \right)^2 d\beta,
\]
where we set \( \beta = \beta_1 + i\beta_2 \). The argument of [23, §11] can now be adapted easily to show that \( J - J_L \ll L^{-1} \), provided that (4.5) is satisfied. This completes the proof of the first statement of the lemma.

It thus remains only to comment on the fact that the inequality \( \dim \mathcal{M}_v \geq ms - Rr \) is really satisfied under the stated conditions. If the manifold \( \mathcal{M}_v \) contains a non-singular point, the statement follows from the Implicit Function Theorem, and it is a consequence of basic algebraic geometry if \( \mathbb{K}_v = \mathbb{C} \) is algebraically closed ([25, Chapter I.6, Corollary 1.7]). Finally, when \( \mathbb{K}_v = \mathbb{R} \) and \( d \) is odd, the same conclusion has been established by Schmidt [22, §2]. □

Theorem 1.2 is now immediate upon combining all estimates hitherto obtained. Furthermore, we have the stronger statement that
\[
N_m(P) = \Pi^{ms-Rd} \prod_{v \in \Omega(\mathbb{K})} \chi_v + O(\Pi^{ms-Rd-\delta}),
\]
where the product over all places of \( \mathbb{K} \) converges absolutely, provided the hypotheses of Theorem 1.1 are true, and the main term is positive if additionally either \( d \) is odd or \( \mathbb{K} \) is totally imaginary, and furthermore either of the two conditions
\[
ms - \dim \text{Sing}_m \mathbf{F} \geq d^{2d-1} (R^2 d^2 + Rm)^{2d-2}
\]
and
\[
s - \dim \text{Sing}^s \mathbf{F} > 2^{d-1} (d - 1) Rd^{2d-1} (R^2 d^2 + Rm)^{2d-2}
\]
is satisfied.
