Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
INTRODUCTION

The coronavirus disease 2019 (COVID-19) pandemic, caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), has imposed an unprecedented health care crisis across the globe. Health care efforts across the world have been diverted to tackling the pandemic since early 2020. Hospitals and health care systems have undertaken major restructuring in an effort to deliver health care to an increasing number of patients affected by COVID-19. Although great focus has been placed on treating those individuals suffering from COVID-19, clinicians must simultaneously balance caring for patients who are not actively infected. In anticipation of an exponential increase in COVID-19 cases, health care systems developed strategies to channel available resources to meet the rapidly rising demands of COVID-19. This change was noticed significantly in the field of invasive cardiology as well. Many cardiac catheterization and electrophysiology (EP) laboratories canceled elective procedures to limit the burden on hospital resources and preserve personal protective equipment (PPE). Major societies published guidance statements delineating patient selection for procedures during the exponential phase of the pandemic growth.1 Patient care was triaged and those waiting for elective procedures were managed with expectant care or noninvasive approaches to preserve hospital resources and personnel. In the current article, we review the impact of the COVID-19 pandemic and its response to the volume of interventional cardiology (IC) and EP procedures across the world.
Impact on Interventional Cardiology Procedures

Onset of the COVID-19 pandemic led to immediate cessation of multiple clinical services in the field of interventional cardiology for better resource allocation and avoidance of potential exposure, across various countries. The British Cardiovascular Interventional society conducted a retrospective study of all percutaneous coronary interventions (PCI) in the United Kingdom during the lockdown imposed by the pandemic and compared them to PCI volumes in the pre-pandemic period. They showed that PCI volumes fell down by 49% with the greatest decrease in PCI for stable angina (66% reduction). PCI for ST-elevation MI (STEMI) was also down by 33%. Interestingly, the decline in volume was higher in older patients and in minorities. In another study from the United Kingdom, Mohamed and colleagues evaluated trends in all inpatient cardiac procedures to understand national trends during the lockdown period. Data on interventional cardiac catheterization, PCI, electrophysiological (CIED implantation, catheter ablation), structural (TAVR), and surgical (CABG, SAVR, MVR) procedures were collected and compared with trends in preceding years. Overall procedural volume fell down by approximately 89% in April and May 2020 during the lockdown, with cardiac catheterization and CIED implantation being the most affected. In addition, after adjusting for baseline comorbidities, patients undergoing PCI, and CIED implantation in the lockdown period had higher odds of mortality. A 24% reduction (29% for NSTEMI and 18% for STEMI) in overall PCI volume for acute MI was also reported from a multicenter analysis from Ireland.

Despite prioritization of STEMI care, when other interventional services were limited during the lockdown, a reduction was seen in STEMI activations and primary PCI procedures being performed, partly related to patient’s reluctance to seek medical care during an ongoing pandemic. A single-center cross-sectional study from Germany reported a 50% reduction in admissions and primary PCI for acute MI during the early part of the pandemic than the pre-pandemic level. More importantly, patients presenting with an acute MI during the pandemic had symptoms for a longer duration, presented with lower LV ejection fraction, had more immediate complications and 3 times higher mortality than the pre-pandemic levels. Similar results have been reported from other European countries such as Italy and Portugal. A systematic review pooling data from 32 studies showed significantly prolonged door to balloon time and worse inpatient mortality for primary PCI for STEMI during the pandemic than prepandemic times. To better understand STEMI care during the pandemic, multicenter registries were developed. The International Study on Acute Coronary Syndromes–ST-Elevation Myocardial Infarction (ISACS-STEMI) registry included data from 6609 patients that underwent primary PCI at 77 hospitals in 18 European countries. There was a significant reduction in the volume of primary PCI in 2020 than in 2019, along with significantly longer door to balloon times, and higher in-hospital mortality. The NACMI (North American COVID-19 and STEMI) prospective registry was developed to track STEMI management trends in patients with COVID-19. This prospective multicenter study showed that patients with COVID-19 presenting with STEMI were less likely to receive primary PCI than controls and had higher rates of a composite of death, stroke, recurrent MI, and need for repeat revascularization.

Data on change in transcatheter aortic valve implantation volumes during the pandemic has been limited than studies evaluating PCI. Although experience from the United Kingdom showed no significant decline, a survey from Asia showed a 25% reduction in case of volume due to the pandemic.

IMPACT ON ELECTROPHYSIOLOGY PROCEDURES

Response to the pandemic has also led to a reduction in EP procedures performed. During the surge of the pandemic, most EP programs only performed emergent procedures giving priority to ventricular tachycardia storms (ES), refractory device infections requiring lead/device extraction, urgent pacemaker and generator changes in PM-dependent patients A survey of 27 hospitals in the greater Philadelphia region evaluated the impact of COVID-19 on EP procedural volumes. Data on procedural volumes in this study were generated from manufacturer sales records. This study showed that the onset of COVID-19 cases in the geographic region was associated with a reduction in both catheter ablation and device implantation procedures (Fig. 1). Monthly arrhythmia ablation procedures decreased by 88.4% from a bi-weekly baseline of 241 procedures before the onset of the US COVID-19 outbreak to 28 in late April 2020. Similarly, pacemaker and implantable cardioverter-defibrillator procedures decreased by 74.4% (398–102 implants) over the same time interval.

Li and colleagues evaluated EP procedural volumes at three centers during a surge of COVID-19 in China, Italy, and United Kingdom.
three centers, all elective EP procedures were canceled with an overall volume being less than 5% of normal volumes. In addition, all EP personnel were deployed for delivering emergency care out of EP. Arbelo and colleagues reported a reduction in overall cardiac implantable electronic device (CIED) volumes in Spain as well during this period.\(^\text{14}\) In this study, data from 9 hospitals spanning 2017 to 2020 in the Catalonia province were aggregated. Compared with the pre–COVID-19 period, an absolute decrease of 56.5% was observed (54.7% in PM and 63.7% in ICD) in CIED implantation rates. Interestingly, there were no statistically significant differences in the type of PM or ICD implanted. An analysis of all cardiac procedures in the United Kingdom also revealed an 89% and 56% reduction in catheter ablation and CIED implantation procedures in April 2020 compared with similar time periods in preceding years.\(^\text{3}\) Similar reductions in CIED volumes from Germany and Italy have been reported as well.\(^\text{15,16}\)

**RESUMPTION OF PROCEDURES – PRECAUTIONS AND UNIVERSAL TESTING**

Following periods of lockdown in various geographic regions, the resumption of elective procedures presented a challenge. Although measures to screen for symptomatic individuals for COVID-19 were widely available, the risk of asymptomatic carriers transmitting the infection to health care workers and other patients remained. Several infection control precautions were undertaken at many centers to combat this risk. As more tests became available, universal testing of patients had led to a safer resumption of elective services.

A prospective study of universal testing of all patients undergoing interventional and EP procedures has provided insight into a strategy of safe resumptions of elective procedures.\(^\text{17}\) In this study conducted at the University of Pennsylvania, the following measures were instituted—universal surgical masks and temperature screening for all employees and patients, automated telephone preprocedure symptom screening for patients, strict restrictions on visitors for inpatients and outpatients, and universal preprocedure PCR testing to detect SARS-CoV-2 virus in patients undergoing elective or urgent procedures. Additional precautions to prevent cross-contamination were implemented at all feasible sites (Table 1). All inpatients undergoing cardiac catheterization or EP procedures underwent nasopharyngeal swabs
for SARS-CoV-2 PCR testing performed at the hospital whereby the procedure was being performed. Outpatients were encouraged to undergo preprocedural testing at a satellite clinic 24 hours before the scheduled procedure to offload burden at the main hospital.

Over a study period of 1 month, a total of 215 patients underwent 252 elective or urgent procedures (128 catheterization and 124 EP procedures). 56% of procedures were performed on outpatients. Among 111 outpatients, 53 (47.7%) underwent testing at an off-site facility. All catheterization procedures were performed under moderate sedation; 30.6% of EP procedures were conducted under general anesthesia. Of 215 patients tested, 2 (0.9%) tested positive for SARS-CoV-2. No patients who tested negative at the time of their procedure subsequently tested positive for SARS-CoV-2, and no staff members developed any symptoms concerning COVID-19 during the universal testing period. During a follow-up telephone survey, two-thirds of patients reported that preprocedural testing did not change their comfort level in getting the procedure performed, and the rest reported increased comfort.

**IMPACT ON TRAINEES**

Not surprisingly, reduction in procedural volumes during the COVID-19 pandemic has impacted the training of fellows enrolled in interventional and EP training programs. Singla and colleagues conducted a survey of all EP fellows and program directors in the United States to assess the impact of the pandemic on EP training and education.\(^\text{18}\) Out of 99 fellows that responded, 98% reported a decrease in their procedural volume and 55% of fellows reported a period of furlough or quarantine during the acute surge of COVID-19. A similar survey of 14 interventional cardiology programs in New York City also reported a significant reduction in catheterization procedures performed by fellows.\(^\text{19}\) In this survey, more than two-thirds of interventional program directors opined that the pandemic has moderately to severely impacted fellowship training. 21% felt that fellows would graduate without performing 250 percutaneous coronary interventions (PCI), which is considered a minimum cut-off for graduation. A third of fellows and program directors felt that fellowship training should be extended to those impacted by the pandemic. Shah and colleagues conducted a larger survey through the Society for Cardiovascular Interventions and Angiography to which 135 interventional fellows responded.\(^\text{20}\) By March 2020, only 43% of the respondents reported performing greater than 250 PCIs. With continued pandemic restrictions on elective procedures until the end of the fellowship, only 70% felt they would reach the minimum procedural volume cut-off for graduation. In addition to procedural volumes, trainees have also felt significant challenges due to the cancellation of in-person academic conferences and transition to purely web-based education. Job opportunities have dwindled down due to financial constraints imposed by the pandemic as well. Finally, the influence of the pandemic on fellow well-being cannot be ignored.\(^\text{21}\)

| Table 1 | Representative example of precautions in the interventional and electrophysiology laboratories during the resumption of elective cases |
|---|---|
| **Risk** | **Proposed Measures** |
| Coming and leaving in same scrubs | It is prohibited to come to work and leave with the same scrubs. |
| Common computer | Only work on personal laptops. Avoid sharing of computers (keyboards – difficult to clean) |
| Consent | Transition to verbal/e-consent |
| Contact | PPE as needed (gloves/ mask) |
| Collecting PPE | Individualized packs |
| Lead aprons | Wipe and store in personal space |
| Control room equipment | Wipe Prucka before and after the case. Wear gloves to operate Prucka. |
| Anesthesia recovery | Wait in the control area, no computer work allowed |
| Provider contact | Limited provider contact unless absolutely necessary |
| Masking | All patients with masks in recovery and transfer |
| Break room | Limited to 2 people at a time for social distancing |

**FUTURE PREPAREDNESS**

The development of a vaccine that is highly effective against moderate to severe COVID-19 has been a remarkable achievement. Increased vaccine uptake has led to a major reduction in hospitalizations for COVID-19 and enabled reopening to a state of near normalcy across the world. However, waves and surges of COVID-19 are expected to happen due to ongoing mutations in the virus and development of variants.\(^\text{22}\) For instance, the
current delta variant leading to surges in some parts of the United States has led to a rapid rise in hospitalizations again, overwhelming health care resources in some hospitals.

Although health care systems are more equipped to handle surges than the onset of the pandemic, these surges can lead to the cancellation of elective procedures again, impacting interventional and EP volumes as well. Lessons learnt from early 2020 can be used to better plan for effective and uninterrupted delivery of routine health care for chronic conditions, whereas handling the acute needs of an ongoing pandemic. There is no doubt that societal and governmental efforts to improve vaccine delivery and overall vaccination rates are pivotal to allow health care systems to effectively function.

CLINICS CARE POINTS

- Evaluation of local variations in COVID-19 cases and prioritization of resources should be implemented in anticipation of surges of infection.
- Remote monitoring of cardiac devices should be emphasized across all EP practices for better uninterrupted delivery of care in the event of further surges.
- Routine preprocedural testing and safety measures such as masking and encouraging vaccination should be routinely implemented until the pandemic resolves.
- Lessons learnt from the impact on procedures during the pandemic should be used for future planning.
