Patrik.Simons@hut.fi, http://www.tcs.hut.fi/~psimons

Abstract

The rules associated with propositional logic programs and the stable model semantics are not expressive enough to let one write concise programs. This problem is alleviated by introducing some new types of propositional rules. Together with a decision procedure that has been used as a base for an efficient implementation, the new rules supplant the standard ones in practical applications of the stable model semantics.

1 Introduction

Logic programming with the stable model semantics has emerged as a viable method for solving constraint satisfaction problems [4, 5]. The state-of-the-art system smodels [6] can often handle non-stratified programs with tens of thousands of rules. However, propositional logic programs can not compactly encode several types of constraints. For example, expressing the subsets of size $k$ of an $n$-sized set as stable models requires on the order of $nk$ rules. In order to remedy this problem, we improve upon the techniques of smodels, by extending the semantics with some new types of propositional rules:

- choice rules for encoding subsets of a set,
- constraint rules for enforcing cardinality limits on the subsets, and

*The financial support of the Academy of Finland and the Helsinki Graduate School in Computer Science and Engineering is gratefully acknowledged.
bullet weight rules for writing inequalities over weighted linear sums.

The extended semantics is not based on subset-minimal models as is the case for disjunctive logic programs. For instance, the choice rule is more of a generalization of the disjunctive rule of the possible model semantics [7].

A system that computes the stable models of programs containing the new rules has been implemented [9], and it has successfully been applied to deadlock and reachability problems in a class of Petri nets [3]. Other problem domains, such as planning and configuration, will benefit by the improved rules as well. The system is based on smodels 1.10 from which it evolved.

The new rules and the stable model semantics are introduced in Section 2. A decision procedure for the extended syntax is presented in Section 3, and some important implementation details are described in Section 4. Experimental results are found in Section 5. Readers not familiar with monotonic functions should consult the appendix.

2 The Stable Model Semantics

Let Atoms be a set of primitive propositions, or atoms, and consider logic programs consisting of rules of the form

\[ h \leftarrow a_1, \ldots, a_n, \text{not } b_1, \ldots, \text{not } b_m, \]

where the head \( h \) and the atoms \( a_1, \ldots, a_n, b_1, \ldots, b_m \) in the body are members of Atoms. Call the expression \( \text{not } b \) a not-atom — atoms and not-atoms are referred to as literals.

The stable model semantics for a logic program \( P \) is defined as follows [2]. The reduct \( P^A \) of \( P \) with respect to the set of atoms \( A \) is obtained by

1. deleting each rule in \( P \) that has a not-atom \( \text{not } x \) in its body such that \( x \in A \), and by

2. deleting all not-atoms in the remaining rules.

Definition 1. A set of atoms \( S \) is a stable model of \( P \) if and only if \( S \) is the deductive closure of \( P^S \) when the rules in \( P^S \) are seen as inference rules.

In order to facilitate the definition of more general forms of rules, we introduce an equivalent characterization of the stable model semantics.
Proposition 1. We say that \( f_P : 2^{\text{Atoms}} \to 2^{\text{Atoms}} \) is a closure if

\[
 f_P(S) = \{ h \mid h \leftarrow a_1, \ldots, a_n, \text{not } b_1, \ldots, \text{not } b_m \in P, \\
 a_1, \ldots, a_n \in f_P(S), \ b_1, \ldots, b_m \notin S \}. 
\]

Let

\[
 g_P(S) = \bigcap \{ f_P(S) \mid f_P : 2^{\text{Atoms}} \to 2^{\text{Atoms}} \text{ is a closure} \}. 
\]

Then, \( S \) is a stable model of the program \( P \) if and only if

\[
 S = g_P(S). 
\]

Proof. Note that the deductive closure of the reduct \( P^S \) is a closure, and note that for every \( f_P \) that is a closure, the deductive closure of \( P^S \) is a subset of \( f_P(S) \). □

A stable model is therefore a model that follows from itself by means of the smallest possible closure. In other words, a stable model is a supported model, and this is the essence of the semantics.

Definition 2. A basic rule \( r \) is of the form

\[
 h \leftarrow a_1, \ldots, a_n, \text{not } b_1, \ldots, \text{not } b_m
\]

and is interpreted by the function \( f_r : 2^{\text{Atoms}} \times 2^{\text{Atoms}} \to 2^{\text{Atoms}} \) as follows.

\[
 f_r(S, C) = \{ h \mid a_1, \ldots, a_n \in C, \ b_1, \ldots, b_m \notin S \}. 
\]

The function \( f_r \) produces the result of a deductive step when applied to a candidate stable model \( S \) and its consequences \( C \).

Definition 3. A constraint rule \( r \) is of the form

\[
 h \leftarrow k \{ a_1, \ldots, a_n, \text{not } b_1, \ldots, \text{not } b_m \}
\]

and is interpreted by

\[
 f_r(S, C) = \{ h \mid |\{a_1, \ldots, a_n\} \cap C| + |\{b_1, \ldots, b_m\} - S| \geq k \}. 
\]

The constraint rule can be used for testing the cardinality of a set of atoms. The rule \( h_1 \leftarrow 2 \{a, b, c, d\} \) states that \( h_1 \) is true if at least 2 atoms in the set \( \{a, b, c, d\} \) are true. The rule \( h_2 \leftarrow 1 \{ \text{not } a, \text{not } b, \text{not } c, \text{not } d \} \), on the other hand, states that \( h_2 \) is true if at most 3 atoms in the set are true.
**Definition 4.** A choice rule $r$ is of the form

$$\{h_1, \ldots, h_k\} \leftarrow a_1, \ldots, a_n, \text{not } b_1, \ldots, \text{not } b_m$$

and is interpreted by

$$f_r(S, C) = \{h \mid h \in \{h_1, \ldots, h_k\} \cap S, a_1, \ldots, a_n \in C, b_1, \ldots, b_m \notin S\}.$$  

The choice rule is typically used when one wants to implement optional choices. The rule $\{a\} \leftarrow b, \text{not } c$ declares that if $b$ is true and $c$ is false, then $a$ is one or the other.

**Definition 5.** Finally, a weight rule $r$ is of the form

$$h \leftarrow \{a_1 = w_{a_1}, \ldots, a_n = w_{a_n}, \text{not } b_1 = w_{b_1}, \ldots, \text{not } b_m = w_{b_m}\} \geq w,$$

for $w_{a_i}, w_{b_i} \geq 0$, and is interpreted by

$$f_r(S, C) = \{h \mid \sum_{a_i \in C} w_{a_i} + \sum_{b_i \notin S} w_{b_i} \geq w\}.$$  

The weight rule is a generalization of the constraint rule. If every literal in the body of a weight rule has weight 1, then the rule behaves precisely as a constraint rule.

**Definition 6.** Let $P$ be a set of rules. As before we say that $f_P : 2^{Atoms} \rightarrow 2^{Atoms}$ is a closure if

$$f_P(S) = \bigcup_{r \in P} f_r(S, f_P(S)),$$

and we define

$$g_P(S) = \bigcap \{f_P(S) \mid f_P : 2^{Atoms} \rightarrow 2^{Atoms} \text{ is a closure}\}.$$  

Then, $S$ is a stable model of the program $P$ if and only if

$$S = g_P(S).$$

The motivation for defining constraint, choice, and weight rules is that they can be easily and efficiently implemented and that they are quite expressive. For example, the constraint rule

$$h \leftarrow k \{a_1, \ldots, a_n, \text{not } b_1, \ldots, \text{not } b_m\}$$
replaces the program

\[ h \leftarrow a_{i_1}, \ldots, a_{i_{k_1}}, \text{not } b_{j_1}, \ldots, \text{not } b_{j_{k_2}} \mid k_1 + k_2 = k, \]

\[ 1 \leq i_1 < \cdots < i_{k_1} \leq n, \ 1 \leq j_1 < \cdots < j_{k_2} \leq m \}\]

which contains \( \binom{n+m}{k} \) rules.

Thus, a constraint rule guarantees that if the sum of the number of atoms in its body that are in a stable model and the number of not-atoms in its body that are not is at least \( k \), then the head is in the model. Similarly, if the body of a choice rule agrees with a stable model, then the rule motivates the inclusion of any number of atoms from its head. A weight rule

\[ h \leftarrow \{ a_1 = w_{a_1}, \ldots, a_n = w_{a_n}, \text{not } b_1 = w_{b_1}, \ldots, \text{not } b_m = w_{b_m} \} \geq w, \]

in turn, will force the head to be a member of a stable model \( S \) if

\[ \sum_{a_i \in S} w_{a_i} + \sum_{b_j \not\in S} w_{b_j} \geq w. \]

**Example 1.** The stable models of the program

\[ \{ a_1, \ldots, a_n \} \leftarrow \]

\[ \text{false} \leftarrow \{ a_1 = w_1, \ldots, a_n = w_n \} \geq w \]

\[ \text{true} \leftarrow \{ a_1 = v_1, \ldots, a_n = v_n \} \geq v \]

containing the atom \( \text{true} \) but not the atom \( \text{false} \) correspond to the ways one can pack a subset of \( a_1, \ldots, a_n \) in a bin such that the total weight is less than \( w \) and the total value is at least \( v \). The individual weights and values of the items are given by respectively \( w_1, \ldots, w_n \) and \( v_1, \ldots, v_n \).

**Example 2.** The satisfying assignments of the formula

\[ (a \lor b \lor \neg c) \land (\neg a \lor b \lor \neg d) \land (\neg b \lor c \lor d) \]

correspond to the stable models of the program

\[ \{ a, b, c, d \} \leftarrow \]

\[ \text{false} \leftarrow \text{not } a, \text{not } b, c \]

\[ \text{false} \leftarrow a, \text{not } b, d \]

\[ \text{false} \leftarrow b, \text{not } c, \text{not } d \]

that do not contain \( \text{false} \).
3 The Decision Procedure

For an atom $a$, let $\text{not}(a) = \neg a$, and for a not-atom $\neg a$, let

$$\text{not}(\neg a) = a.$$ 

For a set of literals $A$, define

$$\text{not}(A) = \{\text{not}(a) \mid a \in A\}.$$ 

Let $A^+ = \{a \in \text{Atoms} \mid a \in A\}$ and let $A^- = \{a \in \text{Atoms} \mid \neg a \in A\}$. Define $\text{Atoms}(A) = A^+ \cup A^-$, and for a program $P$, define $\text{Atoms}(P) = \text{Atoms}(L)$, where $L$ is the set of literals that appear in the program.

A set of literals $A$ is said to cover a set of atoms $B$ if $B \subseteq \text{Atoms}(A)$, and $B$ is said to agree with $A$ if

$$A^+ \subseteq B \quad \text{and} \quad A^- \subseteq \text{Atoms} - B.$$ 

Algorithm 1 displays a decision procedure for the stable model semantics. The function $\text{smodels}(P, A)$ returns true whenever there is a stable model of $P$ agreeing with $A$, and it relies on the three functions $\text{expand}(P, A)$, $\text{conflict}(P, A)$, and $\text{lookahead}(P, A)$.

Let $A' = \text{expand}(P, A)$. We assume that

**E1** $A \subseteq A'$ and that

**E2** every stable model of $P$ that agrees with $A$ also agrees with $A'$.

Moreover, we assume that the function $\text{conflict}(P, A)$ satisfies the two conditions

**C1** if $A$ covers $\text{Atoms}(P)$ and there is no stable model that agrees with $A$, then $\text{conflict}(P, A)$ returns true, and

**C2** if $\text{conflict}(P, A)$ returns true, then there is no stable model of $P$ that agrees with $A$.

In addition, $\text{lookahead}(P, A)$ is expected to return literals not covered by $A$.

**Theorem 2.** Let $P$ be a set of rules and let $A$ be a set of literals. Then, there is a stable model of $P$ agreeing with $A$ if and only if $\text{smodels}(P, A)$ returns true.
Algorithm 1 A decision procedure for the stable model semantics

function \textit{smolds}(P, A)
\begin{align*}
  & A' := \text{expand}(P, A) \\
  & \text{if} \ \text{conflict}(P, A') \ \text{then} \\
  & \quad \text{return false} \\
  & \text{else if} \ A' \text{ covers } \text{Atoms}(P) \ \text{then} \\
  & \quad \text{return true} \\
  & \quad \{ A'^+ \text{ is a stable model} \} \\
  & \text{else} \\
  & \quad x := \text{lookahead}(P, A') \\
  & \quad \text{if} \ \text{smolds}(P, A' \cup \{x\}) \ \text{then} \\
  & \quad \quad \text{return true} \\
  & \quad \text{else} \\
  & \quad \quad \text{return } \text{smolds}(P, A' \cup \{\text{not } (x)\}).
\end{align*}

function \textit{expand}(P, A)
\begin{align*}
  & \text{repeat} \\
  & \quad A' := A \\
  & \quad A := \text{Atleast}(P, A) \\
  & \quad A := A \cup \{ \text{not } x \mid x \in \text{Atoms}(P) \text{ and } x \notin \text{Atmost}(P, A) \} \\
  & \text{until} \ A = A' \\
  & \text{return } A.
\end{align*}

function \textit{conflict}(P, A)
\begin{align*}
  \{ \text{Precondition: } A &= \text{expand}(P, A) \} \\
  & \text{if} \ A'^+ \cap A^- \neq \emptyset \ \text{then} \\
  & \quad \text{return true} \\
  & \text{else} \\
  & \quad \text{return false.}
\end{align*}

function \textit{lookahead}(P, A)
\begin{align*}
  & B := \text{Atoms}(P) - \text{Atoms}(A); \ B := B \cup \text{not } (B) \\
  & \text{while } B \neq \emptyset \ do \\
  & \quad \text{Take any literal } x \in B \\
  & \quad A' := \text{expand}(P, A \cup \{x\}) \\
  & \quad \text{if} \ \text{conflict}(P, A') \ \text{then} \\
  & \quad \quad \text{return } x \\
  & \quad \text{else} \\
  & \quad \quad B := B - A' \\
  & \text{return } \text{heuristic}(P, A).
\end{align*}
Proof. Let $nc(P, A) = Atoms(P) - Atoms(A)$ be the atoms not covered by $A$. We prove the claim by induction on the size of $nc(P, A)$.

Assume that the set $nc(P, A) = \emptyset$. Then, $A'$ covers $Atoms(P)$ by E1 and $smodels(P, A)$ returns true if and only if $conflict(P, A')$ return false. By E2, C1, and C2, this happens precisely when there is a stable model of $P$ agreeing with $A$.

Assume $nc(P, A) \neq \emptyset$. If $conflict(P, A')$ returns true, then $smodels(P, A)$ returns false and by E2 and C2 there is no stable model agreeing with $A$. On the other hand, if $conflict(P, A')$ returns false and $A'$ covers $Atoms(P)$, then $smodels(P, A)$ returns true and by E2 and C1 there is a stable model that agrees with $A$. Otherwise, induction together with E1 and E2 show that $smodels(P, A' \cup \{x\})$ or $smodels(P, A' \cup \{not(x)\})$ returns true if and only if there is a stable model agreeing with $A$.

Let $S$ be a stable model of $P$ agreeing with the set of literals $A$. Then, $f_r(S, S) \subseteq S$ for $r \in P$, and we make the following observations. Let

$$
min_r(A) = \bigcap_{A^+ \subseteq C, A^{-} \cap C = \emptyset} f_r(C, C)
$$

be the inevitable consequences of $A$, and let

$$
max_r(A) = \bigcup_{A^+ \subseteq C, A^{-} \cap C = \emptyset} f_r(C, C)
$$

be the possible consequences of $A$. Then,

1. for all $r \in P$, $S$ agrees with $min_r(A)$,

2. if there is an atom $a$ such that for all $r \in P$, $a \notin max_r(A)$, then $S$ agrees with $\{not a\}$,

3. if the atom $a \in A$, if there is only one $r \in P$ for which $a \in max_r(A)$, and if there exists a literal $x$ such that $a \notin max_r(A \cup \{x\})$, then $S$ agrees with $\{not(x)\}$, and

4. if $not a \in A$ and if there exists a literal $x$ such that for some $r \in P$, $a \in min_r(A \cup \{x\})$, then $S$ agrees with $\{not(x)\}$.

The four statements help us deduce additional literals that are in agreement with $S$. Define $Atleast(P, A)$ as the smallest set of literals containing $A$ that
Lemma 3. The function Atleast($P, A$) is monotonic in its second argument.

Proof. Observe that the function $\min_r(B)$ is monotonic and that the function $\max_r(B)$ is anti-monotonic. Hence,

$$\{a \in \min_r(B) \mid r \in P\},$$

$$\{\text{not } a \mid a \in \text{Atoms}(P) \text{ and for all } r \in P, a \not\in \max_r(B)\},$$

and

$$\{\text{not } (x) \mid \text{there exists not } a \in B \text{ and } r \in P \text{ such that } a \not\in \min_r(B \cup \{x\})\}$$

are monotonic with respect to $B$. Assume that there exists $a \in B$ such that $a \in \max_r(B)$ for only one $r \in P$ and $a \not\in \max_r(B \cup \{x\})$. If $B \subseteq B'$ and $a \not\in \max_r(B')$, then

$$\text{not } a \in \{\text{not } a \mid a \in \text{Atoms}(P) \text{ and for all } r \in P, a \not\in \max_r(B')\} \subseteq f(B').$$

Consequently, both $a, \text{not } a \in f(B')$ and therefore

$$\min_r(f(B')) = \text{Atoms}$$

and

$$\max_r(f(B')) = \emptyset.$$

It follows that $f(f(B')) = \text{Atoms}(P) \cup \text{not} (\text{Atoms}(P))$. Thus, $f^2$ is monotonic and has a least fixed point. Finally, notice that $f$ has the same fixed points as $f^2$. \hfill \Box

We conclude,

**Proposition 4.** If the stable model $S$ of $P$ agrees with $A$, then $S$ agrees with Atleast($P, A$).
Furthermore, we can bound the stable models from above.

**Proposition 5.** For a choice rule \( r \) of the form
\[
\{h_1, \ldots, h_k\} \leftarrow a_1, \ldots, a_n, \text{not } b_1, \ldots, \text{not } b_m,
\]
let
\[
f'_r(S, C) = \{h \in \{h_1, \ldots, h_k\} \mid a_1, \ldots, a_n \in C, \ b_1, \ldots, b_m \notin S\},
\]
and for any other type of rule, let \( f'_r(S, C) = f_r(S, C) \). Let \( S \) be a stable model of \( P \) that agrees with \( A \). Define \( \text{Atmost}(P, A) \) as the least fixed point of
\[
f'(B) = \bigcup_{r \in P} f'_r(A^+, B - A^-) - A^-.
\]
Then, \( S \subseteq \text{Atmost}(P, A) \).

**Proof.** Note that \( f'_r(S, C) \) is anti-monotonic in its first argument, i.e., \( S \subseteq S' \) implies \( f'_r(S', C) \subseteq f'_r(S, C) \), and monotonic in its second argument. Fix a program \( P \), a stable model \( S \) of \( P \), and a set of literals \( A \) such that \( S \) agrees with \( A \). Define
\[
f(B) = \bigcup_{r \in P} f_r(S, B)
\]
and
\[
f'(B) = \bigcup_{r \in P} f'_r(A^+, B - A^-) - A^-.
\]
Let \( L \) be the least fixed point of \( f' \). Since \( S \) agrees with \( A \),
\[
f_r(S, S \cap L) \subseteq f'_r(A^+, S \cap L - A^-) - A^-,
\]
and \( f(S \cap L) \subseteq f'(S \cap L) \subseteq L \). Hence, the least fixed point of \( f(S \cap -) \), which is equal to the least fixed point of \( f \), is a subset of \( L \). In other words, \( S \subseteq L \).

It follows that \( \text{expand}(P, A) \) satisfies the conditions E1 and E2. The function \( \text{conflict}(P, A) \) obviously fulfills C2, and the next proposition shows that also C1 holds.
Proposition 6. If $A = \operatorname{expand}(P, A)$ covers the set $\operatorname{Atoms}(P)$ and $A^+ \cap A^- = \emptyset$, then $A^+$ is a stable model of $P$.

Proof. Assume that $A = \operatorname{expand}(P, A)$ covers $\operatorname{Atoms}(P)$ and that $A^+ \cap A^- = \emptyset$. Then, $A^+ = \operatorname{Atmost}(P, A)$. As $f_r(A^+, B) \subseteq \operatorname{min}_r(A) \subseteq A$ for $B \subseteq A^+$,

$$f_r(A^+, B) = f'_r(A^+, B - A^-) - A^-$$

for every $B \subseteq A^+$. Thus, $A^+$ is the least fixed point of

$$f(B) = \bigcup_{r \in P} f_r(A^+, B),$$

from which we infer that $A^+$ is a stable model of $P$. \hfill \Box

3.1 Looking Ahead and the Heuristic

Besides $\operatorname{Atleast}(P, A)$ and $\operatorname{Atmost}(P, A)$, there is a third way to prune the search space. If the stable model $S$ agrees with $A$ but not with $A \cup \{x\}$ for some literal $x$, then $S$ agrees with $A \cup \{\neg (x)\}$. One can therefore avoid futile choices if one looks ahead and tests whether $A \cup \{x\}$ gives rise to a conflict for some literal $x$. Since $x' \in \operatorname{expand}(P, A \cup \{x\})$ implies

$$\operatorname{expand}(P, A \cup \{x'\}) \subseteq \operatorname{expand}(P, A \cup \{x\})$$

due to the monotonicity of $\operatorname{Atleast}(P, A)$ and $\operatorname{Atmost}(P, A)$, it is not even necessary to examine all literals not covered by $A$. That is, if we have tested $x$, then we do not have to test the literals in $\operatorname{expand}(P, A \cup \{x\})$.

When looking ahead fails to find a literal that causes a conflict, one falls back on a heuristic. For a literal $x$, let

$$A_p = \operatorname{expand}(P, A \cup \{x\})$$

and

$$A_n = \operatorname{expand}(P, A \cup \{\neg (x)\}).$$

Assume that the search space is a full binary tree of height $H$, and let $p = |A_p - A|$ and $n = |A_n - A|$. Then,

$$2^{H-p} + 2^{H-n} = 2^H \frac{2^n + 2^p}{2^{p+n}}$$

11
is an upper bound on the size of the remaining search space. Minimizing this number is equal to minimizing
\[ \log \frac{2^n + 2^p}{2^{p+n}} = \log(2^n + 2^p) - (p + n). \]

Since
\[ 2^{\max(n,p)} < 2^n + 2^p \leq 2^{\max(n,p) + 1} \]
is equivalent to
\[ \max(n, p) < \log(2^n + 2^p) \leq \max(n, p) + 1 \]
and
\[ -\min(n, p) < \log(2^n + 2^p) - (p + n) \leq 1 - \min(n, p), \]
it suffices to maximize \( \min(n, p) \). If two different literals have equal minimums, then one chooses the one with the greater maximum, \( \max(n, p) \).

\section{Implementation Details}

The deductive closures \( \text{Atleast}(P, A) \) and \( \text{Atmost}(P, A) \) can both be implemented using two versions of a linear time algorithm of Dowling and Gallier [1]. The basic algorithm associates with each rule a counter that keeps track of how many literals in the body of a rule are not included in a partially computed closure. If a counter reaches zero, then the head of the corresponding rule is included in the closure. From the inclusion follows changes in other counters, and in this manner is membership in the closure propagated.

We begin with basic rules of the form
\[ h \leftarrow a_1, \ldots, a_n, \neg b_1, \ldots, \neg b_m. \]

For every rule \( r \) we create a literal counter \( r.\text{literal} \), which is used as above, and an inactivity counter \( r.\text{inactive} \). If the set \( A \) is a partial closure, then the inactivity counter records the number of literals in the body of \( r \) that are in \( \neg (A) \). The counter \( r.\text{inactive} \) is therefore positive, and the rule \( r \) is inactive, if one can not now nor later use \( r \) to deduce its head. For every atom \( a \) we create a head counter \( a.\text{head} \) that holds the number of active rules with head \( a \).

Recall that a literal can be brought into \( \text{Atleast}(P, A) \) in four different ways. We handle the four cases with the help of the three counters.
1. If \( r.\text{literal} \) reaches zero, then the head of \( r \) is added to the closure.

2. If \( a.\text{head} \) reaches zero, then \( \neg a \) is added to the closure.

3. If \( a.\text{head} \) is equal to one and \( a \) is in the closure, then every literal in the body of the only active rule with head \( a \) is added to the closure.

4. Finally, if \( a \) is the head of \( r \), if \( \neg a \) is in the closure, and if \( r.\text{literal} = 1 \) and \( r.\text{inactive} = 0 \), then there is precisely one literal \( x \) in the body of \( r \) that is not in the closure, and \( \neg (x) \) is added to the closure.

Constraint rules and choice rules are easily incorporated into the same framework. Specifically, one does neither use the first nor the fourth case together with choice rules, and one does not compare the literal and inactivity counters of a constraint rule \( h \leftarrow k \{a_1, \ldots, a_n, \neg b_1, \ldots, \neg b_m\} \) with zero but with \( m + n - k \). A weight rule

\[
 h \leftarrow \{a_1 = w_{a_1}, \ldots, a_n = w_{a_n}, \neg b_1 = w_{b_1}, \ldots, \neg b_m = w_{b_m}\} \geq w,
\]

is managed using the upper and lower bound of the sum of the weights in its body. Given a set of literals \( A \), the lower bound is

\[
\sum_{a_i \in A^+} w_{a_i} + \sum_{b_i \in A^-} w_{b_i},
\]

and the upper bound is

\[
\sum_{a_i \notin A^+} w_{a_i} + \sum_{b_i \notin A^-} w_{b_i}.
\]

If the upper bound is less than \( w \), then the rule is inactive, and if the lower bound is at least \( w \), then the head is in the closure.

Notice that the implementation provides for incremental updates to the closure \( \text{Atleast}(P, A) \) as \( A \) changes. This is crucial for achieving a high performance.

Since the function \( \text{Atmost}(P, A) \) is anti-monotonic, it will shrink as \( A \) grows. It is no good computing \( \text{Atmost}(P, A) \) anew each time \( A \) is modified. Instead all atoms that might not be in the newer and smaller closure are found using a variant of the basic algorithm. By inspecting these atoms it is possible to decide which ones must be in the closure, and then the basic algorithm can again be used to compute the final closure. A small example will make the method clear.
Example 3. Suppose $P$ is the program

\begin{align*}
a &\leftarrow b & a &\leftarrow \text{not } c \\
b &\leftarrow a & a &\leftarrow \text{not } d,
\end{align*}

and suppose $A$ has changed from the empty set to $\{d\}$. Then, we have already computed $\text{Atmost}(P, \emptyset) = \{a, b\}$, and we want to find $\text{Atmost}(P, A)$. If $r$ is the rule $a \leftarrow \text{not } d$, then the counter of $r$ is at first zero and then changes to one as $d$ becomes a member of $A$. Therefore, we deduce that $a$ is possibly not a part of the new closure. The basic algorithm proceeds to increment the counters of $b \leftarrow a$, removing $b$, and $a \leftarrow b$, where it stops. At this point the counter of the rule $a \leftarrow \text{not } c$ is still zero, and we note that $a$ must be part of the closure. Including $a$ causes the counter of $b \leftarrow a$ to decrease to zero. Consequently, $b$ is added to the closure and the counter of $a \leftarrow b$ is decremented. Since nothing more remains to be done, the final closure is $\{a, b\}$.

One can argue, in this particular example, that $a$ follows from the rule $a \leftarrow \text{not } c$ and need not be removed in the first stage of the procedure. However, in general it is not possible to decide whether an atom is in the final closure by inspecting the rules of which it is a head. Notwithstanding, we can make improvements based upon this observation.

For every atom $a$, create a source pointer whose mission is to point to the first rule that causes $a$ to be included in the closure. During the portion of the computation when atoms are removed from the closure, we only remove atoms which are to be removed due to a rule in a source pointer. For if the rule in a source pointer does not justify the removal of an atom, then the atom is reentered into the closure in the second phase of the computation. In practice, this simple trick yields a substantial speedup of the computation of $\text{Atmost}(P, A)$.

5 Experiments

We will search for sets of binary words of length $n$ such that the Hamming distance between any two words is at least $d$. The size of the largest of these sets is denoted by $A(n, d)$. For example, $A(5, 3) = 4$ and any 5-bit one-error-correcting code contains at most 4 words. One such code is $\{00000, 00111, 11001, 11110\} = \{0, 7, 25, 30\}$. Finding codes becomes very quickly very hard. For instance, it was only recently proved that $A(10, 3) = 72$ [10].

14
Construct a program that includes a rule
\[ w_i \leftarrow \text{not } w_{j_1}, \ldots, \text{not } w_{j_k} \]
for every word \( i = 0, \ldots, 2^n \) such that \( j_1, \ldots, j_k \) are the words whose distance to \( i \) is positive and less than \( d \). Then, the stable models of the program are the maximal codes with Hamming distance \( d \). Add the rule
\[ \text{true} \leftarrow m \{ w_0, \ldots, w_2^n \} \]
and every model containing \( \text{true} \) is a code of size at least \( m \). For the purpose of making the problem a bit more tractable, we only consider codes that include the zero word.

The test results are tabulated below. The minimum, maximum, and average times are given in seconds and are calculated from ten runs on randomly shuffled instances of the program. All tests were run under Linux 2.2.6 on a 233MHz Pentium II with 128MB of memory.

| Problem | Min   | Max  | Average |
|---------|-------|------|---------|
| A(5,3) \( \geq 4 \) | 0.01  | 0.02 | 0.02    |
| A(5,3) \( < 5 \)  | 0.00  | 0.02 | 0.02    |
| A(6,3) \( \geq 8 \) | 0.02  | 0.04 | 0.03    |
| A(6,3) \( < 9 \)  | 0.16  | 0.18 | 0.17    |
| A(7,3) \( \geq 16 \)| 0.14  | 14.19| 6.77    |
| A(7,3) \( < 17 \) | 69.08 | 72.29| 70.55   |
| A(8,3) \( \geq 20 \)| 6.39  | 202.41| 55.98   |
| A(8,3) \( < 21 \) | > 1 week |      |         |
| A(9,5) \( \geq 6 \) | 3.18  | 8.71 | 4.81    |
| A(9,5) \( < 7 \)  | 1127.03 | 1162.10 | 1145.85 |

6 Conclusion

We have presented some new and more expressive propositional rules for the stable model semantics. A decision procedure, which has been used as a base for an efficient implementation, has also been described. We note that the decision problem for the extended semantics is NP-complete, as a proposed stable model can be tested in polynomial time. Accordingly, the exponential worst case time-complexity of the decision procedure comes as no surprise.

The literals that \( \text{smodels}(P,A) \) can branch on are, in this paper, the literals that do not cover \( \text{Atoms}(P) – \text{Atoms}(A) \). In previous work, for instance in Niemelä and Simons [6, 8], the eligible literals have also been required to appear in the form of not-atoms in the program. This additional restriction can reduce the search space, and a similar requirement is, of course, also possible here. The question of which literals one necessarily must consider as branch points is left to future research.
Let $X$ be a set and let $f : 2^X \to 2^X$ be a function. If $A \subseteq B$ implies $f(A) \subseteq f(B)$, then $f$ is monotonic.

**Lemma.** Let $f : 2^X \to 2^X$ be a monotonic function, and let $A \subseteq X$. If $f(A) \subseteq A$, then lfp $(f) \subseteq A$, where lfp $(f)$ denotes the least fixed point of $f$. 

**Proof.** Define

$$S = \bigcap_{f(A) \subseteq A} A \quad \text{and} \quad (f(X) \subseteq X).$$

Then, $f(A) \subseteq A$ implies $S \subseteq A$, which in turn implies $f(S) \subseteq f(A)$ by the monotonicity of $f$. Hence, $f(S) \subseteq A$, and consequently

$$f(S) = \bigcap_{f(A) \subseteq A} f(S) \subseteq \bigcap_{f(A) \subseteq A} A = S.$$

Now, $f(S) \subseteq S$ implies $f(f(S)) \subseteq f(S)$, which by the definition of $S$ implies $S \subseteq f(S)$. Thus, $S = f(S)$. Moreover, for any fixed point $A$,

$$f(A) \subseteq A \quad \text{implies} \quad S \subseteq A,$$

and hence lfp $(f) = S$ by definition.

Similarly, $A \subseteq f(A)$ implies $A \subseteq gfp (f)$ for the greatest fixed point of $f$. Notice that if $X$ is finite, then lfp $(f) = f^n(\emptyset)$ for some $n \leq |X|$ since $f(\emptyset) \subseteq \text{lfp}(f)$. Furthermore, observe that if we are given $k$ monotonic functions $f_1, \ldots, f_k$, then the least fixed point of

$$g(A) = \bigcup_{i=1}^k f_i(A)$$

is the limit of any nest

$$A_{n+1} = A_n \cup f_{i(n)}(A_n), \quad A_0 = \emptyset \text{ and } f_{i(n)}(A_n) \subseteq A_n \Rightarrow \forall j f_j(A_n) \subseteq A_n.$$ 

In other words, the least fixed point of $g$ can be computed by repeated applications of $f_1, \ldots, f_k$.
