Abstract

To investigate the mechanism of phytobezoar dissolution by Coca-Cola®, persimmon phytobezoar pieces removed from a 60-year-old Japanese woman were analyzed by energy dispersive X-ray spectroscopy. The amount of calcium significantly decreased after dissolution treatment using Coca-Cola®, suggesting a potential contribution of calcium to dissolution mechanisms. Moreover, immersion in Coca-Cola® for 120 hours on the exterior surface revealed that Coca-Cola® did not permeate persimmon phytobezoars. This is the first study to investigate the mechanisms of persimmon phytobezoar permeability and dissolution induced by Coca-Cola®.

Key words: persimmon phytobezoar, diospyrobezoar, cola beverages, dissolution

(DOI: 10.2169/internalmedicine.55.6985)

Introduction

A bezoar is a rounded mass in the digestive tract comprising a tightly packed collection of semi-digested or undigested material. Since the first report in 2002 by Ladas et al. (1), there have been many case reports and series describing the successful clinical outcome of bezoars treated with Coca-Cola® or other carbonated drinks (2-10). In a report by Ladas et al., 24 articles including 46 patients were reviewed and the authors stated that treatment with Coca-Cola® led to phytobezoar resolution in 91.3% of the cases, either as a sole treatment or in combination with an endoscopic procedure (11). We recently investigated the efficiency of in vitro dissolution of phytobezoars by cola beverages. We found that Coca-Cola® and Coca-Cola Zero® showed higher lytic action than the control (water) (12). However, the mechanism of phytobezoar dissolution by cola beverages has never been investigated.

The permeability of cola beverages into persimmon phytobezoars is another uninvestigated issue. A persimmon phytobezoar, i.e., diospyrobezoar, is the most common type of bezoar (13). Unlike other phytobezoars, persimmon phytobezoars are harder and more difficult to fragment or dissolve into small pieces (14). For instance, reports from Korea indicated that 3 L of cola lavage or drinking resulted in complete dissolution of non-persimmon phytobezoars in 66.7% (four of six) of cases, while it was not at all effective in patients with persimmon phytobezoars (0 of 11 cases) (8). Our previous case series also showed that persimmon phytobezoars were not dissolved by Coca-Cola® beverages alone and they required endoscopic or surgical removal (6). Such clinical results indicate that persimmon phytobezoars are resistant to cola beverages due to their structural rigidity, which prevents permeation of liquid.

In this paper, we performed two basic studies to reveal the mechanisms of persimmon phytobezoar dissolution by Coca-Cola®. First, to investigate the permeation properties,
The bezoar was cut into three pieces and the middle piece was used in an infrared spectroscopy analysis (Fig. 1A, 2A). The persimmon phytobezoar pieces were placed on the cut surface side (Fig. 1B, 2B, left) or the exterior surface side (Fig. 1C, 2B, right) in cell strainers with 40 μm pores (Corning Inc., Corning, USA). The cell strainers were set in 50 mL conical polystyrene tubes and the bottom 80% of the pieces was immersed in Coca-Cola® (The Coca-Cola Co., Atlanta, USA) for 120 hours at room temperature (25°C) without stirring. Coca-Cola® was replaced every 24 hours. Subsequently, the persimmon phytobezoar pieces were removed from the cell strainers and photographs of the cell strainers and phytobezoar pieces were taken.

**Scanning electron microscopy and energy dispersive X-ray spectroscopy analyses**

To investigate the elemental composition of the persimmon phytobezoar samples, we used S4800 scanning electron microscopy (Hitachi, Tokyo, Japan) and an EDAX Genesis APEX2 system (Ametek, Paoli, USA). The middle piece of the persimmon phytobezoar pieces that was not used in the immersion experiment was used as a control. The net intensity of each element was measured at three different points on the cut surface of the pieces immersed in Coca-Cola® on the cut surface side (Fig. 1B) for 120 hours and that of the control, respectively. We analyzed the spectrum of the energy dispersive X-ray spectroscopy results using the Genesys software program (Ametek). The amount of each element was quantified using the standardless EDAX ZAF quantification method. For comparisons of the elemental composition, Student’s t-tests were performed using the JMP 8.0.1 software program (SAS Institute, Cary, USA). A p value less than 0.05 was considered to be statistically significant. Elemental mapping of iron was also performed with S4800 scanning electron microscopy and EDAX Genesis APEX2.

**Results**

Photographs of the cell strainers taken after the immersion experiment are shown in Fig. 2C and D. A greater number of dissolved fragments were observed in the cell strainer in which a bezoar piece was placed on the cut surface side (Fig. 2C) than that of the exterior surface side (Fig. 2D). Photographs of the persimmon phytobezoar pieces after the immersion experiment showed that the color of the cut surface was completed changed to black when immersed on the cut surface side (Fig. 2E, left), whereas that of the exterior surface side was only partly changed (Fig. 2E, right). Notably, in the latter piece, color changes were observed along cracks that were incidentally made when cutting the bezoar into pieces, and changes were observed in a limited area close to the surface without cracks.

Scanning electron microscopy showed that there were no obvious changes in the microstructure of the cut surface between samples before (Fig. 3A) and after dissolution by...
Coca-Cola® (Fig. 3B). The net intensities of the elements determined by energy-dispersive X-ray spectroscopy of the persimmon phytobezoar pieces are shown in Table. The amount of calcium was significantly reduced and that of sulfur was increased after dissolution treatment by Coca-Cola®. The sodium concentration was also decreased, but it was not statistically significant. There were no changes in the amount of carbon, oxygen, or potassium. The samples were likely contaminated with osmium during sample preparation for the electron microscopy analysis because it was used as a fixing agent. A scanning electron microscopy image of the cut surface of the piece before Coca-Cola® treatment (Fig. 3C) and elemental mapping of calcium measured on the same field (Fig. 3D) revealed that calcium was diffusely deposited throughout the phytobezoar piece.

Discussion

This report is the first study to investigate the permeability of persimmon phytobezoars. Immersion of phytobezoar pieces in Coca-Cola® for 120 hours resulted in a color change to black. The black color was most likely generated by the caramel color contained in Coca-Cola®. Therefore, we consider that the area that changed to black color is equal to the area permeated by Coca-Cola®. The immersion experiment revealed that Coca-Cola® did not permeate the bezoar even after immersion for 120 hours. Our study results are consistent with those previously reported that indicated that Coca-Cola® is ineffective for dissolving persimmon phytobezoars (6, 8, 15-17). In our previous study, we investigated the ultrastructure of a persimmon bezoar by scanning electron microscopy and found that a high-density layer 20- to 50-μm thick constituted the exterior of the phytobezoar (18). Moreover, microgranules formed the exterior surface of the persimmon phytobezoar, which aggregated and created an almost seamless structure with only a few slits. The present study further revealed that infiltration of Coca-Cola® was observed only in a narrow area adjacent to the surface (Fig. 2E). Therefore, according to the microstructural properties revealed by our previous study and the results shown in the present study, we speculate that the almost seamless, dense layers of the exterior surface of the persimmon phytobezoar plays a major role in preventing percolation of liquids.

It was also noteworthy that Coca-Cola® permeated along the cracks, but it did not penetrate into the entire bezoar even after immersion for 120 hours. The inner part of the persimmon phytobezoar comprised sheet-like structures of curved or wiggly shapes, which constituted a honeycomb-like appearance (Fig. 2A and B). Although unoccupied areas existed in the inner part, continuous arrangement of the sheet-like structures likely blocks permeation of liquids (18).

Energy-dispersive X-ray spectroscopy revealed that the amount of calcium was significantly reduced after immers-
Figure 3. Electron microscopy images. There are no obvious changes in the microstructure of the cut surface between samples before (A) and after dissolution by Coca-Cola® (B). A scanning electron microscopy image of the cut surface of the piece before Coca-Cola® treatment (C) and an elemental mapping image of calcium (D). The calcium element is shown in red and is diffusely deposited in the cut surface.

Table. Net Intensities of Elements Determined by Energy-dispersive X-ray Spectroscopy in a Persimmon Phytobezoar before and after Dissolution by Coca-Cola.

| Element | Before | After | p value |
|---------|--------|-------|---------|
| C       | 127.2 ± 15.8 | 131.6 ± 23.2 | 0.801   |
| O       | 60.2 ± 7.0   | 60.9 ± 10.8   | 0.928   |
| Na      | 14.4 ± 2.2   | 10.8 ± 0.9    | 0.091   |
| S       | 3.1 ± 1.0    | 13.0 ± 1.6    | 0.002   |
| K       | 2.0 ± 2.4    | 1.4 ± 0.3     | 0.708   |
| Ca      | 4.2 ± 0.6    | 1.3 ± 0.3     | 0.008   |
| Os      | 8.4 ± 2.4    | 6.6 ± 0.4     | 0.308   |

The authors state that they have no Conflict of Interest (COI).
