Testosterone Concentrations in Diabetic and Nondiabetic Obese Men

OBJECTIVE — To determine the prevalence of subnormal testosterone concentrations in patients with obesity and with type 2 diabetes in a primary care clinic population.

RESEARCH DESIGN AND METHODS — Free testosterone concentrations of 1,849 men (1,451 nondiabetic and 398 diabetic) in the Hypogonadism In Males (HIM) study were analyzed. The HIM study was a U.S.-based cross-sectional study designed to define the prevalence of hypogonadism in men aged ≥45 years. Free testosterone was measured by equilibrium dialysis.

RESULTS — The prevalence of subnormal free testosterone concentrations in lean, over-weight, and obese nondiabetic men was 26% (n = 275), 29% (n = 687), and 40% (n = 489), respectively (P < 0.001 for trend), and 44% (n = 36), 44% (n = 135), and 50% (n = 227), respectively, in diabetic men (P = 0.46 for trend within group and P < 0.05 compared with nondiabetic men). The mean free testosterone concentration of diabetic men was significantly lower than that of nondiabetic men. Free testosterone concentrations were negatively and significantly (P < 0.001) related to age (r = −0.37). BMI (r = −0.18), and sex hormone–binding globulin (r = −0.11) in multiple regression analysis. The average decline of free testosterone concentrations was 7.8 pg/ml per decade in nondiabetic men and 8.4 pg/ml per decade in diabetic men.

CONCLUSIONS — Forty percent of obese nondiabetic men and 50% of obese diabetic men aged ≥45 years have subnormal free testosterone concentrations. In view of its high prevalence, obesity is probably the condition most frequently associated with subnormal free testosterone concentrations in males. The concomitance of diabetes is associated with an additional increase in the prevalence of subnormal free testosterone concentrations.

trations even when they have a normal weight (1).

Because of the rising prevalence of obesity in the U.S. and the rest of the world, it is imperative that the prevalence of low free testosterone in obese men be defined. Furthermore, the magnitude of the contribution of obesity to subnormal free testosterone associated with type 2 diabetes needs to be quantitated. To answer these issues, we analyzed free testosterone concentrations in the obese nondiabetic and diabetic men in the HIM study. The hypotheses tested were that 1) obese men have a higher prevalence of subnormal free testosterone concentrations than nonobese men and 2) that men with diabetes have a higher prevalence of subnormal free testosterone concentrations than nondiabetic men, both obese and nonobese.

**RESEARCH DESIGN AND METHODS** — The HIM study recruited 2,165 men in 95 centers across the U.S. Study criteria have been published previously (7). In brief, all men aged ≥45 years had a blood sample taken in the morning (between 8:00 A.M. and noon). Blood was analyzed for concentrations of total testosterone, free testosterone, bioavailable testosterone, and SHBG. Total testosterone and SHBG were determined by radioimmunoassay, free testosterone by equilibrium dialysis, and bioavailable testosterone by the ammonium sulfate precipitation method (Esoterix, Calabasas Hills, CA). The lower limit for free testosterone of the reference laboratory was 50 pg/ml (0.174 nmol/l). The lower limit for bioavailable testosterone was 90 ng/dl (0.313 nmol/l).

The HIM study had 474 men with self-reported diabetes; 1,691 men did not have diabetes. Judging by their medication lists, we excluded men who were taking antiretroviral drugs (33 men), narcotics (78 men), or testosterone replacement therapy (33 men). We also excluded men currently using steroids, narcotics, antibiotics (to eliminate men with acute illnesses), or drugs that affect the dopaminergic pathway (34 men). The prevalence of low free testosterone in all these excluded men (n = 178) was 50%. Men with missing data on BMI or hormone concentrations were also excluded from analysis (n = 138). We report on the findings from 1,849 men, 398 of whom had diabetes.

Group comparisons were performed by one-way ANOVA, t tests, Mann-Whitney rank sum tests, and $\chi^2$ tests as appropriate. Data that were not normally distributed were log-transformed to perform the parametric statistical tests. Total testosterone, free testosterone, bioavailable testosterone, SHBG, age, and BMI were not normally distributed and were log-transformed. Pearson correlation and multiple linear regression analyses between variables were done using Sigma-Stat software (SPSS, Chicago, IL). Using the statistical program SYSTAT-12, we ran a stepwise regression with a forward and backward stepping generalized linear model analysis to find out the equation that relates the effects of BMI and age in diabetic and nondiabetic men on free testosterone levels. Adjustment for age and BMI in group comparisons was done with ANCOVA and generalized linear model analysis. For purposes of uniformity in comparisons, data were adjusted to the mean age (60.9 years) and BMI (29.7 kg/m$^2$) of the whole population. Data are presented as means ± SD.

**RESULTS** — Thirty-five percent of all men had subnormal free testosterone concentrations, irrespective of diabetes status. The mean age, BMI, and hormone concentrations of diabetic and nondiabetic men are shown in Table 1. The crude prevalence of subnormal free testosterone concentrations in diabetic and nondiabetic men was 51 and 31%, respectively. Diabetic men were older and heavier than nondiabetic men. Even after adjustment for age and BMI, the prevalence of subnormal free testosterone concentrations in the diabetic men was higher than that in nondiabetic men (45% vs. 33%). As expected, there was an increase in the prevalence of subnormal free testosterone concentrations with age. Figure 1 shows the prevalence of subnormal free testosterone concentrations in study subjects divided into quartiles of age.

**Prevalence of subnormal free testosterone in lean, overweight, and obese men**

We analyzed the hormonal concentrations of study subjects after stratifying them in lean (BMI <25 kg/m$^2$), overweight (BMI 25–29.9 kg/m$^2$), and obese (BMI ≥30 kg/m$^2$) categories (Table 1). The data were adjusted for age and SHBG differences. There was a significant decline in free testosterone concentrations with BMI in both nondiabetic and diabetic men. Free testosterone concentrations in lean, overweight, and obese nondiabetic men were $62.0 ± 19.4$ pg/ml (0.215 ± 0.067 nmol/l), $60.9 ± 19.3$ pg/ml (0.211 ± 0.067 nmol/l), and $55.5 ± 19.7$ pg/ml (0.193 ± 0.068 nmol/l), respectively (P < 0.001 by ANOVA).

Free testosterone concentrations in lean, overweight, and obese diabetic men were $58.8 ± 19.5$ pg/ml (0.204 ± 0.068 nmol/l), $56.9 ± 19.3$ pg/ml (0.198 ± 0.068 nmol/l), and $50.7 ± 19.4$ pg/ml (0.176 ± 0.068 nmol/l), respectively (P = 0.002 by ANOVA).

The prevalence of subnormal free testosterone concentrations was 26% in lean, 29% in overweight, and 40% in obese nondiabetic men, whereas it was 44, 44, and 50% in lean, overweight, and obese diabetic men, respectively. Diabetic men had a significantly higher prevalence of subnormal free testosterone concentrations in all BMI categories (Table 1). Similar results were obtained when hormonal concentrations were log-transformed and compared (supplementary Table 2, available in an online appendix at http://care.diabetesjournals.org/cgi/content/full/dc09-1649/DC1).

Fifty-one nondiabetic and 57 diabetic men were morbidly obese (BMI ≥40 kg/m$^2$). The mean free testosterone concentrations in morbidly obese nondiabetic and diabetic men were $51.1 ± 19.4$ pg/ml (0.177 ± 0.067 nmol/l) and $45.1 ± 19.4$ pg/ml (0.157 ± 0.067 nmol/l), respectively (P = 0.15 by t test). The prevalence of subnormal free testosterone in morbidly obese nondiabetic and diabetic men was 49 and 55% (P = 0.09 by $\chi^2$ test), respectively.

**Relation of free testosterone with age and BMI**

Free testosterone concentrations were significantly (P < 0.001) and negatively related to age ($r = −0.38$) and BMI ($r = −0.10$). The final equation that described the decline in free testosterone (FT) concentrations with an increase in age and BMI in nondiabetic men was

$$FT = 123.57 - 0.7815 \times \text{age} - 0.5761 \times \text{BMI}$$

where free testosterone is in picograms per milliliter, age is in years, and BMI is weight in kilograms divided by the square of height in meters.

In diabetic men, the equation was

$$FT = 123.57 - 0.8382 \times \text{age} - 0.5761 \times \text{BMI}$$

Diabetes Care, volume 33, number 6, June 2010 1187
Testosterone in diabetic and nondiabetic men

Demographic parameters and hormone concentrations of lean (BMI < 25 kg/m²), overweight (BMI 25–29.9 kg/m²), and obese (BMI ≥ 30 kg/m²) nondiabetic and diabetic men

| Age (years) | Metformin | Sulfonylureas | Thiazolidinediones | Insulin |
|------------|-----------|---------------|--------------------|--------|
| Men with subnormal FT (%) | 35% | 27% | 35% | 35% |
| FT (pg/ml) | 37% | 11% | 37% | 11% |
| Total T (ng/dl) | 37% | 11% | 37% | 11% |
| Bioavailable T (nmol/l) | 37% | 11% | 37% | 11% |
| SHBG (nmol/l) | 37% | 11% | 37% | 11% |

Data are means ± SD. Testosterone concentrations and prevalence of subnormal free testosterone in the lean, overweight, and obese columns were adjusted only for age and SHBG. Testosterone concentrations and prevalence of subnormal free testosterone in columns for diabetic and nondiabetic men were adjusted to the mean age (60.9 years), BMI (29.7 kg/m²), and SHBG concentration (58.4 nmol/l) of the whole population. Testosterone concentrations and prevalence of subnormal free testosterone in the lean, overweight, and obese columns were adjusted for the mean age of 60.9 years, BMI of 29.7 kg/m², and SHBG concentration of 58.4 nmol/l of the whole population. Testosterone concentrations and prevalence of subnormal free testosterone in columns for diabetic and nondiabetic men were adjusted for the mean age of 60.9 years, BMI of 29.7 kg/m², and SHBG concentration of 58.4 nmol/l of the whole population.

Thus, the average reduction in free testosterone concentration with age in nondiabetic and diabetic men was 7.8 and 8.4 pg/ml per decade, respectively. The average reduction in free testosterone concentration if the BMI of the subject increases by 1 kg/m² was 5.76 pg/ml in both diabetic and nondiabetic men.

Free testosterone concentrations were negatively related to SHBG (r = −0.18, P < 0.001). Age was negatively related to BMI (r = −0.16, P < 0.001) and positively to SHBG (r = 0.34, P < 0.001). BMI was negatively related to SHBG (r = 0.28, P < 0.001). We performed multiple linear regression analysis in a model with free testosterone as the dependent variable and age, BMI, and SHBG as the independent variables. Age, BMI, and SHBG were all independent predictors of serum free testosterone (R² of the model was 0.18; standardized [β] coefficients for age, BMI, and SHBG were −0.37, −0.18, and −0.11).

We also analyzed the effect of age and BMI separately in lean, overweight, and obese diabetic and nondiabetic men. The results are presented in Fig. 2. These data show that the relationship of free testosterone with age was stronger in the nonobese men. On the contrary, the relationship of free testosterone with BMI was strongest in obese men.

Prevalence of subnormal free testosterone in diabetic men taking oral hypoglycemics and insulin

Of 398 men with diabetes, 67 were diet controlled with diet, 201 were taking metformin, 204 were taking sulfonylureas, 120 were taking thiazolidinediones, and 60 were taking insulin (insulin monotherapy in 17 and insulin in combination with oral hypoglycemic drugs in 43). The prevalence of subnormal free testosterone was similar (P = 0.40 by χ²) in men treated with diet (43%), metformin (47%), sulfonylureas (54%), thiazolidinediones (48%), and insulin (57%), whether alone or in combination with oral agents.

Bioavailable testosterone

Log-transformed bioavailable testosterone concentrations were lower in diabetic men than in nondiabetic men (supplementary Table 2). Serum bioavailable testosterone concentrations were independently predicted by age, BMI, and SHBG (R² of the model was 0.31; β coefficients for age, BMI, and SHBG were...
The prevalence of subnormal free testosterone (FT) concentrations in diabetic (DM, ◼) and nondiabetic (non-DM, ■) men separated into quartiles of age. Quartile 1 (aged 45–52 years) had 408 nondiabetic and 55 diabetic men. Quartile 2 (aged 53–59 years) had 378 nondiabetic and 82 diabetic men. Quartile 3 (aged 60–68 years) had 326 nondiabetic and 136 diabetic men. Quartile 4 (aged 69–91 years) had 339 nondiabetic and 125 diabetic men. The prevalence of subnormal free testosterone concentrations was calculated in each quartile for nondiabetic and diabetic men. The prevalence was then adjusted to the mean BMI (29.7 kg/m²) of the whole study population. A χ² test was used to compare the prevalence among groups. A similar percentage of nondiabetic and diabetic men in quartile 1 had subnormal free testosterone (18% vs. 18%, P = 0.97). Nondiabetic men had a lower prevalence of subnormal free testosterone than diabetic men in the other three quartiles (quartile 2, 22 vs. 41%, P < 0.01; quartile 3, 32 vs. 50%, P < 0.01; and quartile 4, 58 vs. 67%, P = 0.05).

CONCLUSIONS — In this study, the largest analysis undertaken to define the prevalence of subnormal free testosterone concentrations in obese men, the data show clearly that 40% of all obese nondiabetic men and 49% of morbidly obese nondiabetic men had subnormal free testosterone concentrations. Furthermore, there was an inverse relationship between free testosterone concentrations and BMI. According to the National Health and Nutrition Examination Survey (NHANES) 2003–2004 data, 31% of all adult men in U.S. are obese and 2.8% are morbidly obese (14). Thus, in view of the fact that almost one-third of the U.S. population is obese, these observations have profound pathophysiological, clinical, epidemiological, and public health implications.

This study is also the first to comprehensively assess the comparative prevalence of subnormal free testosterone concentrations with obesity and diabetes separately and together when they coexist.

Our study shows that diabetic men with and without obesity have lower free testosterone concentrations than nondiabetic men after adjustment for age or BMI. The effect of having diabetes on the free testosterone concentration in a 60-year-old man was similar to that of an increase in BMI of 6 kg/m² (equal to weight gain of 25 kg in a 180-cm [6-feet] tall man) in a man without diabetes. The elevated insulin resistance of type 2 diabetic men compared with that of obese men may explain these findings. Cross-sectional analysis of the NHANES III data (101 diabetic and 1,312 nondiabetic men) has shown that low androgens are associated with the presence of diabetes in men (15). The prevalence of low free testosterone concentrations was not mentioned in that analysis. The mean calculated free testosterone concentrations were similar in diabetic and nondiabetic men. We found a small (6%) but statistically significant difference in the age- and BMI-adjusted free testosterone concentrations of diabetic and nondiabetic men. The larger number of diabetic subjects in our study might explain the difference in our data and that from NHANES III. The mean age and BMI of NHANES III subjects (57 years and 29.5 kg/m²) were lower than those of our diabetic study subjects. Consistent with the NHANES III study, we did not find a difference in SHBG concentrations of diabetic and nondiabetic men.

The prevalence of low free testosterone in diabetic men was higher in all BMI categories compared with that in nondiabetic men. Whereas nondiabetic men showed an increase in prevalence of subnormal free testosterone across BMI categories, there was no significant change in the prevalence of low free testosterone with increasing BMI in the diabetic men. This is attributable to the high prevalence of low free testosterone in lean diabetic men (45% after adjustment for age). Nevertheless, we found that free testosterone concentrations decreased significantly with increasing BMI in both diabetic and nondiabetic men. In the morbidly obese subjects, we found that there was a nonsignificant trend toward lower free testosterone concentrations and higher prevalence of subnormal free testosterone in diabetic men compared with that in nondiabetic men. This could be due to...
smaller numbers of morbidly obese men in the study (51 diabetic and 57 nondiabetic).

Free testosterone concentrations were negatively related to age in our study. We found that obese men had a smaller age-related decline of free testosterone concentrations compared with that in nonobese men. This result suggests an independent effect of BMI-related factors on free testosterone concentrations. Although our study cannot answer questions about the causes of low free testosterone in the obese and type 2 diabetic men, several prior studies have addressed this question (10,12,16).

It has been suggested that the increase in adipose tissue mass in obesity may result in increased aromatase activity and thus lead to a greater conversion of testosterone into estradiol (12). An increase in estradiol concentrations would lead to the suppression of hypothalamic gonadotropin-releasing hormone and pituitary gonadotropin secretion. This would result in the reduction of both testosterone secretion by Leydig cells and spermatogenesis in the seminiferous tubules.

Young overweight and obese men are indeed known to have a decrease in sperm count (17). However, there has been no study demonstrating that estradiol concentrations are actually elevated in obese or diabetic patients with subnormal testosterone concentrations. If indeed, this result is confirmed, aromatase inhibition could be a therapeutic strategy in future. Unfortunately, estradiol concentrations are not available in our study.

The other possible mechanism involved in the pathogenesis of obesity-related low free testosterone is insulin resistance. The selective deletion of the insulin receptor gene from neurons results in a syndrome of hypogonadotropic hypogonadism in mice in addition to a state of systemic insulin resistance (16). It is therefore possible that insulin resistance at the hypothalamic level contributes to the pathogenesis of this syndrome. The concurrent presence of marked inflammation may contribute to insulin resistance because inflammatory mediators such as tumor necrosis factor-α and interleukin-6 may interfere with insulin signal transduction (18).

Clearly, further investigation is necessary to define the etiology of this syndrome.

In view of the increasing prevalence of obesity even in younger populations, it would be important to conduct a similar study in young individuals at the prime of their reproductive years. It is relevant that the prevalence of hypogonadotropic hypogonadism is greater than 50% in patients with type 2 diabetes aged between 18 and 35 years (19).

We also found that SHBG concentrations are negatively related to BMI and positively to age. SHBG concentrations decrease with insulin resistance, and low SHBG concentrations are predictive of future development of type 2 diabetes (20). Although this finding has been well estab-

![Figure 2](image-url)
lished in previous studies, the pathophysiological mechanisms behind these associations are not known and need to be explored in future studies.

One of the limitations of our study is that we could not differentiate between type 1 and type 2 diabetes in our study subjects. The presence of diabetes was recorded by a physician. However, because >90% of diabetic individuals have type 2 diabetes and this number is even higher in those aged >45 years, this issue is not likely to affect the overall conclusions of this study. We have previously shown that the prevalence of hypogonadism in type 1 diabetes is markedly lower than that in type 2 diabetes (5). Only 17 patients were receiving insulin monotherapy, and thus they may have type 1 diabetes. Excluding these men did not change the results of the study.

It is well known that there is a significant day-to-day variability in hormone concentrations, especially testosterone. As for most epidemiological or cross-sectional studies, the testosterone concentrations in the HIM study were measured only once. In view of the variability in testosterone concentrations, this is a limitation. However, it is not likely that the prevalence of low testosterone concentrations would have been altered after repeated measurements because the probability of testosterone concentrations rising or falling with repeated measurements is statistically equal. The issue of repeated measurements is important in the context of diagnosing hypogonadism clinically in the context of a single patient. The fact that our study included a moderately large number of participants also helps to diminish the effect of hormonal variability on study effects and the relationship with BMI.

We did not have a validated questionnaire for erectile dysfunction and symptoms of hypogonadism. Therefore, we cannot comment on the frequency of symptomatic hypogonadism in our study. It has been shown in the past that a high percentage of diabetic men with low testosterone concentrations have symptomatic hypogonadism (3,21). Lower testosterone concentrations are inversely related to visceral adiposity (3,22). However, waist circumference or body composition imaging was not available in our study. Another limitation of our study is that the subjects were not required to be fasting when providing blood samples. It has recently been shown that an oral glucose load of 75 g can acutely lower total testosterone concentrations by 25% (23). However, in a prior analysis of these data, no difference was found in total testosterone concentrations from blood samples drawn between 8 A.M. and 10 A.M. vs. 10 A.M. and 12:00 P.M. (7).

In conclusion, 40% of obese nondiabetic men, aged ≥45 years have subnormal free testosterone concentrations; 26% of normal-weight nondiabetic men and 44% of normal-weight diabetic men had subnormal free testosterone concentrations. The combination of obesity and diabetes increases the prevalence of subnormal free testosterone concentrations to 50%. Thus, both obesity and diabetes appear to exert independent effects on the prevalence of low free testosterone concentrations in addition to age. In view of the high rates of prevalence of subnormal free testosterone in patients with obesity or diabetes, concentrations of free testosterone should be measured in these populations especially when these conditions occur concomitantly.
