Abstract

We have studied the quasi-free dissociation of quarkonia through a complex potential which is obtained by correcting both the perturbative and nonperturbative terms of the Cornell potential through the dielectric function in real-time formalism. The real-part of the potential becomes stronger and thus makes the quarkonia more bound whereas the (magnitude) imaginary-part too becomes larger and thus contribute more to the thermal width, compared to the medium-contribution of the Coulomb term alone. These cumulative effects result the quarkonia to dissociate at higher temperatures. Finally we extend our calculation to a medium, exhibiting local momentum anisotropy, by calculating the leading anisotropic corrections to the propagators in Keylshed representation. The presence of anisotropy makes the real-part of the potential stronger but the imaginary-part is weakened slightly. However, since the temperature corrections to the imaginary-part is a small perturbation to the vacuum part, so overall the anisotropy makes the dissociation temperatures higher, compared to isotropic medium.

1 Introduction

The study of the heavy quarkonium states at finite temperature got impetus after the proposal [1] where the dissociation of quarkonium due to the color screening in the deconfined medium signals the formation of quark gluon plasma. The assumption behind the proposal is that the medium effects can be envisaged through a temperature-dependent heavy quark potentials and have been studied over the decades either phenomenologically or through lattice based free energy calculations [2, 3]. In recent years there have been important theoretical developments in heavy quarkonium physics where a sequence of effective field theories (EFT) [4, 5, 6, 7, 8] are derived by exploiting the hierarchy of different scales of heavy quark bound state: $m_Q \gg m_Q v \gg m_Q v^2$, due to its large quark mass ($m_Q$). For example, the heavy quark system can be described by non-relativistic quantum chromodynamics (NRQCD) obtained from QCD by integrating out the mass. To describe the bound state of two quarks, one can further integrate out the typical momentum exchange ($m_Q v$) between the bound quarks [4, 5] and leads to potential non-relativistic QCD (pNRQCD) which describes a bound state by a two point function satisfying the Schrödinger equation through the potentials as the matching coefficients of the Lagrangian. The EFT can also be generalized to finite temperature to justify the use of potential models at finite temperature [9] but the thermal scales ($T$, $gT$ etc.) make the analysis complicated. For example, when the binding energy is larger than the temperature,
there is no medium modifications of the heavy quark potential [9] but the properties of quarkonia states will be affected through the interactions with ultra-soft gluons. As a result the binding energy gets reduced and a finite thermal width is developed due to the medium induced singlet-octet transitions arising from the dipole interactions [9]. This temperature regime is relevant for the $\Upsilon(1S)$ suppression at the LHC. In the opposite limit ($T < gT$), the potential acquires an imaginary component [9]. However beyond leading-order, the above distinctions are no more possible.

In non EFT, the heavy quark potential is defined from the late-time behavior of the Wilson loop [10, 11] and can be directly calculated either in Euclidean-time lattice simulations or in perturbation theory [12]. However at finite temperature, the proper definition of the potential becomes non-trivial. At finite temperature, the Wilson loop now depends on imaginary time and needs to be analytically continued to extract the potential and happens to be complex [13, 9]. The imaginary part of the potential can be interpreted as the Landau damping [14] which describes the decaying of the $Q\bar{Q}$ correlation with its initial state due to scatterings in the plasma.

The separation of thermal scales in EFT ($T \gg gT \gg g^2T$) (in weak-coupling regime), in practice is not evident and one needs lattice techniques to test the approach. To understand the color screening in the strong-coupling regime, lattice calculations of the spatial correlation functions of static quarks are needed. In principle it is possible to study the problem of quarkonium dissolution without any use of potential models. Recently a lot of progress has been made in this direction in which the in-medium properties of different quarkonium states are encoded in spectral functions in terms of the Euclidean meson correlation functions constructed on the lattice [15, 16, 17, 18, 19, 20, 21, 22, 23]. However, the reconstruction of the spectral functions from the lattice meson correlators turns out to be very difficult, and despite several attempts its outcome still remains inconclusive. One remarkable feature of the studies of the lattice meson correlators is their feeble temperature dependence despite the expected color screening. This seems to be puzzling!

Apart from the uncertainty of exact nature of potential at finite temperature there is an arbitrariness in the definition of dissociation criteria. The physical picture of quarkonium dissociation in a deconfined medium has undergone a theoretical refinements over the last couple of years. Experimentally, the properties of thermally produced heavy quarkonium can be observed through the energy spectrum of their decay products (dilepton pair) [24, 25]. The dissociation of quarkonium resonances correspond to the disappearance of their peaks in the dilepton production rate. However, estimating the energy levels from the potential models does not allow one to reconstruct the spectral function. Physically a resonance dissolves into a medium due to the gradual broadening of its peak due to its interaction with the partons in the medium. Earlier it was thought that a quarkonium state is dissociated when the Debye screening becomes so strong that it inhibits the formation of bound states but nowadays a quarkonium is dissociated at a lower temperature [13, 26] even though its binding energy is nonvanishing, rather is overtaken by the Landau-damping induced thermal width [27], obtained from the imaginary part of the potential. Its consequences on heavy quarkonium spectral functions [26, 28], perturbative thermal widths [27, 29] quarkonia at finite
velocity [30], in a T-matrix approach [31, 32, 33, 34, 35], and in stochastic real-time dynamics [36] have been studied. Recently the dynamical evolution of the plasma was combined with the real and imaginary parts of the binding energies to estimate the suppression of quarkonium [37] in RHIC and LHC energies.

As discussed above, the in-medium correction to the potential is always accompanied with both real and imaginary parts. For very small coupling the imaginary part of the potential is actually the dominant source of bound state dissolution. Therefore, any realistic calculation of quarkonium spectral functions should include both real and imaginary parts for the temperature-dependent potential. The hierarchy of scales assumed in weak coupling calculations may not be satisfied and non-perturbative effects may play an important role. Thus, one has to rely on the lattice results. But the imaginary part cannot be extracted from present lattice calculation and inadvertently supports the use of potential models at finite temperature as an important tool to complement the lattice studies. However, the lattice studies hint that the potential has a sizable imaginary component at strong-coupling [27, 38, 39]

Usually potential model studies are limited to the medium-modification of the perturbative part of the potential only. It is found that the bulk properties of the QCD plasma phase, e.g. the screening property, equation of state [40, 41] etc. deviate from the perturbative predictions, even beyond the deconfinement temperature. In the sequel, the phase transition in QCD for physical quark masses is found to be a crossover [42, 43]. It is thus reasonable to assume that the string-tension does not vanish abruptly at the deconfinement point [44, 45, 46], so one should study its effects on heavy quark potential even above $T_c$. This issue, usually overlooked in the literature where only a screened Coulomb potential was assumed above $T_c$ and the linear/string term was neglected, was certainly worth investigation. Sometimes one-dimensional Fourier transform of the Cornell potential was employed with the assumption of color flux tube [47] in one-dimension but at finite temperature, it may not be the case since the flux tube structure may expand in more dimensions [48]. Therefore, it would be better to consider the three-dimensional form of the medium modified Cornell potential. Recently a heavy quark potential was derived by correcting the full Cornell potential, not its Coulomb part alone, with a dielectric function encoding the effects of the deconfined medium [49]. The inclusion of nonvanishing string term, apart from the Coulomb term made the potential more attractive which can be seen by an additional long range Coulomb term, in addition to the conventional Yukawa term. In the short distance limit, the potential reduces to the vacuum one, i.e., $QQ$ pair does not see the medium, giving rise the duality between $V(r, T = 0)$ and $V(0, T)$. On the other hand, in the large distance limit, potential reduces to a long-range Coulomb potential with a dynamically screened-color charge. Thereafter the binding energies and dissociation temperatures of the ground and the lowest-lying states of charmonium and bottomonium spectra have been determined [49, 50].

The discussions on the medium modifications of quarkonium properties referred above are restricted to isotropic medium only, it was until recently where the effect of anisotropy is considered in the heavy-ion collisions [51]. At the very early time of collision, asymptotic weak-coupling enhances the longitudinal expansion substantially than the radial expansion, thus the system becomes colder in the longitudinal direction than in the transverse direction and causes an anisotropy in the momentum space. The anisotropy
thus generated affects the evolution of the system as well as the properties of quarkonium states. In recent years, the effects of anisotropy on both real and imaginary part of the heavy-quark potential and subsequently on the dissociation of quarkonia states have been investigated in an anisotropic medium [54, 55, 56, 57, 58] extensively. Recently we extended our aforesaid calculation [49] for an isotropic medium to a medium which exhibits a local anisotropy in the momentum space by correcting the full Cornell potential through the hard-loop resumed gluon propagator [59]. The presence of anisotropy introduces an angular dependence, in addition to inter-particle separation, to the potential which is manifested in weakening the screening of the potential. As a result the resonances become more bound than in isotropic medium. Since the weak anisotropy represents a perturbation to the (isotropic) spherical potential, we obtained the first-order correction due to the small anisotropic contribution to the energy eigenvalues of spherically-symmetric potential and explored how the properties of quarkonium states change in the anisotropic medium. For example, the dissociation temperatures are found minimum for the isotropic case and increase with the increase of anisotropy.

Now we plan to continue our work to calculate the imaginary part, in addition to the real part of the potential both in isotropic and anisotropic medium by correcting the full Cornell potential, not its Coulomb part alone. Therefore, we first revisit the leading anisotropic corrections to the real and imaginary part of the retarded, advanced and symmetric propagators through their self energies, and then plug in their static limit to evaluate the real and imaginary part of the potential, respectively. This imaginary part provides a contribution to the width (Γ) of quarkonium bound states [13, 27, 14] which in turn determines their dissociation temperatures by the criterion: dissociation point of a particular resonance is defined as the temperature where the twice of the binding energy equals to Γ [20, 26, 60, 61]. The structure of our paper is as follows. Section 2 is devoted to the formalism of the potential in both isotropic and anisotropic medium. So we have started with a review of the retarded, advanced and symmetric propagators and self energies in Keldyash representation and their evaluation in HTL resummed theory in both isotropic and anisotropic medium in Section 2.1. With these ingredients, we calculate the real and imaginary part of the (static) potential and subsequently studied the dissociation of charmonium and bottomonium states by calculating their binding energies and widths for isotropic and anisotropic medium in subsection(s) 2.2 and 2.3, respectively. Moreover we have shown our results and try to explain them in terms of various effects: the contribution of the non-perturbative (string) term, the anisotropy, the screening scale etc. Finally, we conclude our main results in Section 3.

2 Potential in a hot QCD medium

As discussed earlier, any meaningful discussion of quarkonium properties in thermal medium should include both real and imaginary parts for the temperature-dependent potential. The hierarchy of scales assumed in weak coupling calculations may not be satisfied, thus one has to rely on the lattice calculation which cannot
yield the imaginary part unambiguously, so we rely on the potential model to circumvent the problem.

Because of the heavy quark mass \((m_Q)\), the requirement: \(m_Q \gg \Lambda_{QCD}\) and \(T \ll m_Q\) is satisfied for the description of the interactions between a pair of heavy quarks and antiquarks at finite temperature, in terms of a quantum mechanical potential. So we can obtain the medium-modification to the vacuum potential by correcting its both short and long-distance part with a dielectric function \(\epsilon(p)\) encoding the effect of deconfinement \([49]\).  

\[
V(r, T) = \int \frac{d^3p}{(2\pi)^{3/2}} (e^{ip\cdot r} - 1) \frac{V(p)}{\epsilon(p)},
\]

where we have subtracted an \(r\)-independent term (to renormalize the heavy quark free energy) which is the perturbative free energy of quarkonium at infinite separation \([62]\). The functions, \(V(p)\) and \(\epsilon(p)\) are the Fourier transform (FT) of the Cornell potential and the dielectric permittivity, respectively.

To obtain the FT of the potential, we regulate both terms with the same screening scale. However, the different scales for the Coulomb and linear pieces \([63, 64]\) are also studied. At present, we regulate both terms by multiplying with an exponential damping factor and is switched off after the FT is evaluated. This has been implemented by assuming \(r\)- as distribution \((r \to r\exp(-\gamma r))\). The FT of the linear part \(\sigma r\exp(-\gamma r)\) is

\[
\tilde{\sigma}r = -\frac{i}{p\sqrt{2\pi}} \left( \frac{2}{(\gamma - ip)^2} - \frac{2}{(\gamma + ip)^2} \right).
\]

After putting \(\gamma = 0\), we obtain the FT of the linear term \(\sigma r\) as,

\[
\tilde{\sigma}r = -\frac{4\sigma}{p^4\sqrt{2\pi}}.
\]

The FT of the Coulomb piece is straightforward, thus the FT of the full Cornell potential becomes

\[
V(p) = -\sqrt{(2/\pi)} \frac{\alpha}{p^2} - \frac{4\sigma}{\sqrt{2\pi}p^4}.
\]

The dielectric permittivity will be calculated once the self energies and propagators are obtained in HTL resummation theory.

### 2.1 HTL self-energies and propagators

The naive perturbative expansion, when applied to gauge fields, suffers from various singularities and even some physical quantity \textit{viz.} damping rate becomes gauge dependent. Diagrams which are of higher order in the coupling constant \(g\) contribute to leading order. These problems can be partly avoided by using the hard thermal loop (HTL) resummation technique \([65]\) to obtain the consistent results, which are complete to leading-order and also gauge independent. At the same time the infrared behavior is improved by the presence of effective masses in the HTL propagators. The HTL technique has been shown to be equivalent to the transport approach \([66, 67]\) and is more advantageous because it can be naturally extended to fermionic self-energies and to higher-order diagrams beyond the semiclassical approximation.
We shall now calculate the finite temperature self energies and propagator in real-time formalism \cite{68} where the propagators acquire a $2 \times 2$ matrix structure:

\begin{equation}
D^0 = \begin{pmatrix}
D_{11}^0 & D_{12}^0 \\
D_{21}^0 & D_{22}^0
\end{pmatrix},
\end{equation}

where each component has zero and finite temperature part which contains the distribution functions. In equilibrium, the distribution functions correspond to either (isotropic) Bose ($f_B$) or Fermi distribution ($f_F$) function. Away from the equilibrium, the distribution function needs to be replaced by the corresponding non-equilibrium one extracted from viscous hydrodynamics. The nonequilibrium situation arises due to preferential expansion and non zero viscosity and as a consequence, a local anisotropy in momentum space sets in. However we consider a system close to equilibrium where the distribution function can be obtained from an isotropic one by removing particles with a large momentum-component along the direction of anisotropy \cite{51,69}, \textbf{n}, i.e.

\begin{equation}
f_{\text{aniso}}(p) = f_{\text{iso}}\left(\sqrt{p^2 + \xi(p.n)^2}\right) \approx f_{\text{iso}}(p) \left[1 - \xi \frac{(p.n)^2}{2\tau T} (1 \pm f_{\text{iso}}(p))\right].
\end{equation}

The anisotropy parameter $\xi$ is related to the shear viscosity-to-entropy density ($\eta/s$) through the one-dimensional Navier Stokes formula by

\begin{equation}
\xi = \frac{10}{T \tau} \frac{\eta}{s},
\end{equation}

where $1/\tau$ denotes the expansion rate of the fluid element. The degree of anisotropy is generically defined by,

\begin{equation}
\xi = \frac{\langle k_L^2 \rangle}{2 \langle k_T^2 \rangle} - 1,
\end{equation}

where $k_L = \textbf{k}.\textbf{n}$ and $k_T = \textbf{k} - \textbf{n}(\textbf{k}.\textbf{n})$ are the components of momentum parallel and perpendicular to the direction of anisotropy, \textbf{n}, respectively. The positive and negative values of $\xi$ correspond to the squeezing and stretching of the distribution function in the direction of anisotropy, respectively. However, in relativistic nucleus-nucleus collisions, $\xi$ is found to be positive. A useful representation of the propagators in real-time formalism is the Keldysh representation where the linear combinations of four components of the matrix, of which only three are independent, give the relation for the retarded (R), advanced (A) and symmetric (F) propagators, respectively:

\begin{equation}
D_R^0 = D_{11}^0 - D_{12}^0, \quad D_A^0 = D_{11}^0 - D_{21}^0, \quad D_F^0 = D_{11}^0 + D_{22}^0.
\end{equation}

Only the symmetric component involves the distribution functions and is of particular advantage for the HTL diagrams where the terms containing distribution functions dominate. The similar relations for the self energies are:

\begin{equation}
\Pi_R = \Pi_{11} + \Pi_{12}, \quad \Pi_A = \Pi_{11} + \Pi_{21}, \quad \Pi_F = \Pi_{11} + \Pi_{22}.
\end{equation}

Resumming the propagators through the Dyson-Schwinger equation, the retarded (advanced) and symmetric propagators can be written as

\begin{align}
D_{R,A} &= D_{R,A}^0 + D_{R,A}^0 \Pi_{R,A} D_{R,A}, \\
D_F &= D_F^0 + D_R^0 \Pi_R D_F + D_F^0 \Pi_A D_A + D_R^0 \Pi_F D_A.
\end{align}
Substituting the symmetric propagator $D^0_F(P)$ in terms of the retarded and advanced propagator, the resummed symmetric propagator can be expressed as

$$D_F(P) = (1 + 2f_B) \text{sgn}(p_0) [D_R(P) - D_A(P)]$$

$$+ D_R(P) [\Pi_F(P) - (1 + 2f_B) \text{sgn}(p_0) [\Pi_R(P) - \Pi_A(P)]] D_A(P).$$  \hspace{1cm} (13)

To calculate the static potential in isotropic medium, only the temporal component (L) of the propagator is needed so the retarded (advanced) propagator in the simplest Coulomb gauge can be written as

$$D^L_{R,A}(\text{iso}) = D^L_{R,A} + D^L_{R,A}(\text{ iso}) D^L_{R,A}(\text{ iso}) \cdot (14)$$

So far the resummation is done in isotropic medium, however we now extend them in a medium which exhibits a weak anisotropy ($\xi \ll 1$). Therefore we first expand the propagators and self energies around isotropic limit and retain only the linear term:

$$D = D_{\text{iso}} + \xi D_{\text{aniso}}, \quad \Pi = \Pi_{\text{iso}} + \xi \Pi_{\text{aniso}}.$$  \hspace{1cm} (15)

Thus in the presence of small anisotropy, the temporal component of the retarded (advanced) propagator becomes

$$D^L_{R,A(\text{aniso})} = D^L_{R,A(\text{iso})} + D^L_{R,A(\text{iso})} [\Pi^L_{R,A(\text{iso})}(P)] \cdot (16)$$

whereas with the notations for the difference of propagators and self-energies: $\Delta D^L_{R,A(\text{aniso})} = [D^L_{R}(P) - D^L_{A}(P)]$, $\Delta \Pi^L_{R,A(\text{aniso})} = [\Pi^L_{R}(P) - \Pi^L_{A}(P)]$, and $\Delta \Pi^L_{R,A(\text{iso})} = [\Pi^L_{R}(P) - \Pi^L_{A}(P)]$, the symmetric propagator can be obtained [62],

$$D^L_{F(\text{aniso})}(P) = (1 + 2f_B(\text{iso})) \text{sgn}(p_0) \Delta^L_{R,A(\text{aniso})} + 2f_B(\text{iso}) \text{sgn}(p_0) \Delta^L_{R,A(\text{iso})} + D^L_{R}(P) \left[ \Pi^L_{F(\text{aniso})}(P) \right.$$

$$\left. - (1 + 2f_B(\text{iso})) \text{sgn}(p_0) \Delta \Pi^L_{R,A(\text{aniso})} - 2f_B(\text{iso}) \text{sgn}(p_0) \Delta \Pi^L_{R,A}(P) \right] D^L_{A}(P).$$  \hspace{1cm} (17)

To solve the propagators, we will now calculate the gluon self energy from the quark and gluon loops. The contribution of the quark loop [62] to the self energy with external and internal momenta as $P(p_0, p)$ and $K(k_0, k)$, respectively (with $Q = K - P$):

$$\Pi^{\mu\nu}(P) = -\frac{i}{2} N_f g^2 \int \frac{d^4 K}{(2\pi)^4} \text{tr}[\gamma^\mu S(Q)\gamma^\nu S(K)]$$  \hspace{1cm} (18)

gives the retarded self energy

$$\Pi^{\mu\nu}_R(P) = -\frac{i}{2} N_f g^2 \int \frac{d^4 K}{(2\pi)^4} (\text{tr}[\gamma^\mu S_{11}(Q)\gamma^\nu S_{11}(K)] - \text{tr}[\gamma^\mu S_{21}(Q)\gamma^\nu S_{12}(K)])$$  \hspace{1cm} (19)

Redefining the fermionic propagators: $S_{R,A,F}(K) \equiv K \tilde{\Delta}_{R,A,F}(K)$, the longitudinal-part of the self energy becomes, in the limit of massless quarks

$$\Pi^{\mu}_R(P) = -i N_f g^2 \int \frac{d^4 K}{(2\pi)^4} (q_0 k_0 + q \cdot k) \left[ \tilde{\Delta}_F(Q)\tilde{\Delta}_R(K) + \tilde{\Delta}_A(Q)\tilde{\Delta}_F(K) + \tilde{\Delta}_A(Q)\tilde{\Delta}_A(K) + \tilde{\Delta}_R(Q)\tilde{\Delta}_R(K) \right]$$  \hspace{1cm} (20)
In the weak-coupling limit, the internal momentum \((T)\) is much larger than the external momentum \((gT)\), so the retarded self energy in the HTL-approximation simplifies into [62]

\[
\Pi^L_R(P) = \frac{4\pi N_f g^2}{(2\pi)^4} \int dk \int d\Omega f_F(k) \frac{1 - (k \cdot \hat{p})^2}{(k \cdot \hat{p} + p_0 + i\epsilon)^2}.
\]

After convoluting the distribution function, \(f_F\) for quarks in an (weakly) anisotropic medium from (6) the retarded quark self energy becomes

\[
\Pi^L_R(P) = \frac{g^2}{2\pi^2} N_f \sum_{i=0,1} \int_0^\infty k \Phi_{(i)}(k) dk \int_{-1}^1 \Psi_{(i)}(s) ds,
\]

with

\[
\Phi_{(0)}(k) = n_F(k),
\]

\[
\Phi_{(1)}(k) = -\xi n_F(k) \frac{k e^{k/T}}{2T},
\]

\[
\Psi_{(0)}(s) = \frac{1 - s^2}{(s + \frac{p_0 + i\epsilon}{p})^2},
\]

\[
\Psi_{(1)}(s) = \cos^2 \theta_p \frac{s^2(1 - s^2)}{(s + \frac{p_0 + i\epsilon}{p})^2} + \frac{\sin^2 \theta_p}{2} \frac{(1 - s^2)^2}{(s + \frac{p_0 + i\epsilon}{p})^2}.
\]

Here, the angle \((\theta_p)\) is between \(n\) and \(p\) and \(s \equiv \hat{k} \cdot \hat{p}\). After decomposing into isotropic \((\xi = 0)\) and anisotropic \((\xi \neq 0)\) pieces, the isotropic and anisotropic terms become

\[
\Pi^L_{R,(iso)}(P) = N_f g^2 T^2 \left( \frac{p_0}{2p} \ln \frac{p_0 + p + i\epsilon}{p_0 - p + i\epsilon} - 1 \right),
\]

\[
\Pi^L_{R,(aniso)}(P) = N_f g^2 T^2 \left( \frac{1}{6} + \frac{\cos 2\theta_p}{2} \right) + \Pi^L_{R,(iso)}(P) \left( \cos 2\theta_p - \frac{p_0^2}{2p^2} (1 + 3 \cos 2\theta_p) \right),
\]

respectively. In HTL-limit, the structure of gluon-loop contribution is the same as the quark-loop, apart from the degeneracy factor and distribution function, so the quark and gluon loops together give the isotropic part of retarded (advanced) self-energy

\[
\Pi^L_{R, (iso)}(P) = m_D^2 \left( \frac{p_0}{2p} \ln \frac{p_0 + p + i\epsilon}{p_0 - p + i\epsilon} - 1 \right),
\]

with the prescriptions +\(i\epsilon\) (−\(i\epsilon\)), for the retarded (advanced) self-energies, respectively whereas the anisotropic part for the retarded (advanced) self energies are

\[
\Pi^L_{R, (aniso)}(P) = \frac{m_D^2}{6} \left( 1 + \frac{3}{2} \cos 2\theta_p \right) + \Pi^L_{R, (iso)}(P) \left( \cos (2\theta_p) - \frac{p_0^2}{2p^2} (1 + 3 \cos 2\theta_p) \right)
\]

where \(m_D^2 = \frac{2\pi T^2}{6} (N_f + 2N_c)\) is the square of Debye mass.

Similarly the isotropic and anisotropic terms for the temporal component of the symmetric part are given by

\[
\Pi^L_{F,(iso)}(P) = -2\pi im_D^2 T \frac{p}{p} \Theta(p^2 - p_0^2),
\]

\[
\Pi^L_{F,(aniso)}(P) = \frac{3}{2} \pi im_D^2 T \frac{p}{p} \left( \sin^2 \theta_p + \frac{p_0^2}{p^2} (3 \cos^2 \theta_p - 1) \right) \Theta(p^2 - p_0^2).
\]
Thus the gluon self-energy is found to have both real and imaginary part which are responsible for the Debye screening and the Landau damping, respectively where the former is usually obtained from the retarded and advanced self energy and the later is obtained from the symmetric self energy alone.

So, to evaluate the real part of the static potential, the real part of the temporal component of retarded (or advanced) propagator (in static limit) is needed

\[ \Re D_{00}^{R,A}(0,p) = -\frac{1}{(p^2 + m_D^2)} + \xi \frac{m_D^2}{6(p^2 + m_D^2)^2} (3\cos2\theta_p - 1), \tag{29} \]

while for the imaginary part of the potential, the imaginary part of the temporal component of symmetric propagator is given by

\[ \Im D_{00}^F(0,p) = -\frac{2\pi T m_D^2}{p(p^2 + m_D^2)} + \xi \left( \frac{3\pi T m_D^2}{2p(p^2 + m_D^2)^2} \sin^2 \theta_p - \frac{4\pi T m_D^4}{p(p^2 + m_D^2)^3} \left( \sin^2 \theta_p - \frac{1}{3} \right) \right) \tag{30} \]

With these real and imaginary part of the self energies and propagators, we will obtain the (complex) potential in subsection(s) 2.2 and 2.3 for isotropic and anisotropic medium, respectively.

### 2.2 Potential in isotropic medium

#### 2.2.1 Real Part

The real part of the static potential can thus be obtained from eq.(1) by substituting the dielectric permittivity \( \epsilon(p) \) in terms of the physical “11”- component of the gluon propagator. The relation between the dielectric permittivity and the static limit of the “00”-component of gluon propagator in Coulomb gauge is

\[ \epsilon^{-1}(p) = -\lim_{\omega \to 0} \frac{p^2 D_{00}^{00}(\omega,p)}{p^2 + m_D^2}, \tag{31} \]

where the later can be separated into real and imaginary parts:

\[ D_{00}^{00}(\omega,p) = \Re D_{11}^{00}(\omega,p) + \Im D_{11}^{00}(\omega,p). \tag{32} \]

The real and imaginary parts can be further recast in terms retarded/advanced and symmetric parts, respectively

\[ \Re D_{11}^{00}(\omega,p) = \frac{1}{2} (D_{R}^{00} + D_{A}^{00}) \quad \text{and} \quad \Im D_{11}^{00}(\omega,p) = \frac{1}{2} D_{F}^{00}. \tag{33} \]

Therefore, using the real part of retarded (advanced) propagator in isotropic medium

\[ \Re D_{R,A}^{00}(0,p) = -\frac{1}{(p^2 + m_D^2)}, \tag{34} \]

the real-part of the potential becomes

\[ \Re V_{(iso)}(r,T) = \int \frac{d^3p}{(2\pi)^{3/2}} (e^{ip \cdot r} - 1) \left( -\sqrt{\frac{2}{\pi}} \frac{\alpha}{p^2} - \frac{4\pi}{\sqrt{2}p}\right) \left( \frac{p^2}{(p^2 + m_D^2)} \right) \equiv \Re V_{1(iso)}(r,T) + \Re V_{2(iso)}(r,T) \tag{35} \]
Figure 1: The real-part of the static potential with (σ = 0) and without (σ ≠ 0) non-perturbative term in the potential. The left (right) panel of the figure denote the results obtained with the leading-order and lattice-fitted Debye masses, respectively.

where \( \Re V_1(\text{iso}) (r, T) \) and \( \Re V_2(\text{iso}) (r, T) \) correspond to the medium modifications to the Coulomb and string term, respectively. After performing the momentum integration, the Coulomb term becomes

\[
\Re V_1(\text{iso}) (r, T) = -\alpha m_D \left( \frac{e^{-\hat{r}}}{\hat{r}} + 1 \right)
\]

and the string term simplifies into

\[
\Re V_2(\text{iso}) (r, T) = \frac{2\sigma}{m_D} \left( \frac{(e^{-\hat{r}} - 1)}{\hat{r}} + 1 \right)
\]

The full potential in isotropic medium becomes (with \( \hat{r} = rm_D \))

\[
\Re V(\text{iso}) (\hat{r}, T) = \left( \frac{2\sigma}{m_D} - \alpha m_D \right) \frac{e^{-\hat{r}}}{\hat{r}} - \frac{2\sigma}{m_D} \hat{r} + \frac{2\sigma}{m_D} - \alpha m_D,
\]

which is found to have an additional long range Coulomb term, in addition to the conventional Yukawa term. In the small-distance limit (\( \hat{r} \ll 1 \)), the above potential reduces to the Cornell potential, i.e. the \( Q\bar{Q} \)-pair does not see the medium. On the other hand, in the long-distance limit (\( \hat{r} \gg 1 \)), the potential is simplified into, with high temperature approximation:

\[
\Re V(\text{iso}) (r, T) \approx -\frac{2\sigma}{m_D^2} r - \alpha m_D,
\]

which, apart from a constant term, is Coulomb-like potential by identifying \( 2\sigma/m_D^2 \) with the square of the strong coupling \( (g^2) \).

To see the effect of the linear term on the potential, in addition to the Coulomb term, we have plotted the (real-part) potential (in Fig.1) with (σ ≠ 0) and without string term (σ = 0). We found that the inclusion of the linear term makes the potential attractive, compared to potential with the Coulomb term only. Furthermore, to see the effects of the screening scale, we have also computed the potential with the Debye mass in next-to-leading order \( (1.4m_D^{10}) \) which is seen less stronger than the leading-order result.
We have also checked the variation of potential with different temperatures \( \text{viz.} \) at \( 1.2T_c \), \( 2.0T_c \) and \( 2.5T_c \), where the potential is found to decrease with the temperature at large distances and becomes short-range. Thus the deconfinement is reflected clearly in the large-distance behavior of heavy quark potential at finite temperature, where the screening is operative. That is why the in-medium behavior of heavy quark bound states is used to probe the state of matter in QCD thermodynamics. \(^1\)

### 2.2.2 Binding Energy

To understand the in-medium properties of the quarkonium states, one need to solve the Schrödinger equation with the finite temperature potential \((38)\) to obtain the energy eigen values. As seen earlier, in the short-distance limit, the vacuum contribution dominates over the medium contribution whereas in other limit the Coulomb like potential \((39)\) yields the binding energies:

\[
E_{\text{bin}} = \left( \frac{m_Q \sigma^2}{m_\rho^2 n^2} + \alpha m_\rho \right) ; \quad n = 1, 2, \ldots
\]

However in the intermediate-distance \((r \cong D \sim 1)\) scale, the interaction becomes complicated and the potential does not look simpler in contrast to the asymptotic limits, so this limit needs to be dealt numerically with the full potential in a Schrödinger equation.

There are some numerical methods to solve the Schrödinger equation either in partial differential form (time-dependent) or eigen value form (time-independent) by the finite difference time domain method (FDTD) or matrix method, respectively. In the later method, the stationary Schrödinger equation can be solved in a matrix form through a discrete basis, instead of the continuous real-space position basis spanned by the states \( |\vec{x}\rangle \). Here the confining potential \( V \) is subdivided into \( N \) discrete wells with potentials \( V_1, V_2, \ldots, V_{N+2} \) such that for \( i^{\text{th}} \) boundary potential, \( V = V_i \) for \( x_{i-1} < x < x_i ; i = 2, 3, \ldots, (N + 1) \). Therefore for the existence of a bound state, there must be exponentially decaying wave function in the region \( x > x_{N+1} \) as \( x \to \infty \) and has the form:

\[
\Psi_{N+2}(x) = P_E \exp[-\gamma_{N+2}(x-x_{N+1})] + Q_E \exp[\gamma_{N+2}(x-x_{N+1})],
\]

where, \( P_E = \frac{1}{2}(A_{N+2} - B_{N+2}) \), \( Q_E = \frac{1}{2}(A_{N+2} + B_{N+2}) \) and, \( \gamma_{N+2} = \sqrt{2\mu(V_{N+2} - E)} \). The eigenvalues can be obtained by identifying the zeros of \( Q_E \).

The binding energies (in Fig. 2) have mainly two features: First, when the nonperturbative term is included, the binding of \( QQ \) pairs gets stronger with respect to the case where only the Coulomb term is included. Secondly, there is a strong decreasing trend with the temperature. This is due to the fact that the screening becomes always stronger with the temperature, so the potential becomes weaker compared to \( T = 0 \) and results in early dissolution of quarkonia in the medium. Thirdly, the binding energy decreases with the increase of screening scale \((1.4 m_{LO}^D)\). Thus the study of the binding energies is poised to provide a wealth of information about the dissociation pattern of quarkonium states in thermal medium which can further be used to determine the dissociation temperatures.

\(^1\)The real part of the singlet potential indeed coincides with the leading-order result of the so-called singlet free energy \([71]\) because it contain entropy contribution.
Figure 2: Variation of the binding energies for $J/\psi$ (left) and $\Upsilon$ (right) states with the temperature (in units of critical temperature, $T_c$), respectively in an isotropic medium. The Debye mass used in the calculation is at the leading order.

2.2.3 Imaginary Part

The imaginary part of the potential originates from the static limit of symmetric self energy. Cutting rules at finite temperature allows one to obtain the imaginary part by cutting open one of the hard thermal loop of the HTL propagator which represents physically the inelastic scattering of the off-shell gluon off a thermal gluon [9, 14, 27, 60], i.e. $g + (Q\bar{Q}) \rightarrow g + Q + \bar{Q}$. The imaginary part of the potential plays an important role in weakening the bound state peak or transforming it to mere threshold enhancement. It leads to a finite width ($\Gamma$) for the resonance peak in the spectral function, which, in turn, determines the dissociation temperature. Dissociation is expected to occur while the (twice) binding energy decreases with the temperature and becomes equal to $\sim \Gamma$ [20, 26].

To obtain the imaginary part of the potential in isotropic medium, we write the temporal component of the symmetric propagator from (30) for $\xi = 0$, in the static limit,

$$\Im D_{F^{(iso)}}^{00}(0, p) = -\frac{2\pi T m_D^2}{p(p^2 + m_D^2)^2}. \quad (42)$$

However the same (42) could also be obtained for partons with space-like momenta ($p_0^2 < p^2$) from the retarded (advanced) self energy (24), using the relation [14, 56]:

$$\ln \frac{p_0 + p \pm i\epsilon}{p_0 - p \pm i\epsilon} = \ln \frac{p_0 + p}{p_0 - p} \pm i\pi \theta(p^2 - p_0^2). \quad (43)$$

Thus the imaginary part of the symmetric propagator (42) gives the dielectric function in isotropic medium:

$$\epsilon^{-1}(p) = -\pi T m_D^2 \frac{p^2}{p(p^2 + m_D^2)^2}. \quad (44)$$
One can then similarly find the imaginary part of the potential from the definition of potential (1)

$$\Im V(r, T) = -\int \frac{d^3 p}{(2\pi)^3/2} (\exp[i p \cdot r] - 1) \left(-\frac{2 \alpha}{\pi p^2} - \frac{4\sigma}{\sqrt{2\pi p^4}}\right)p^2 \left[\frac{-\pi T m_D^2}{p(p^2 + m_D^2)}\right]$$

$$\equiv \Im V_{1}(r, T) + \Im V_{2}(r, T),$$

(45)

where $\Im V_{1}(r, T)$ and $\Im V_{2}(r, T)$ are the imaginary parts of the potential due to the medium modification to the short-distance and long-distance terms, respectively:

$$\Im V_{1}(r, T) = -\frac{\alpha}{2\pi^2} \int d^3 p (\exp[i p \cdot r] - 1) \left[\frac{\pi T m_D^2}{p(p^2 + m_D^2)}\right]$$

$$\Im V_{2}(r, T) = -\frac{4\sigma}{(2\pi)^2} \int d^3 p (\exp[i p \cdot r] - 1) \frac{1}{p^2} \left[\frac{\pi T m_D^2}{p(p^2 + m_D^2)}\right]$$

(46)

After performing the integration, the contribution due to the short-distance term to imaginary part becomes (with $z = p/m_D$)

$$\Im V_{1}(r, T) = -2\alpha T \int_{0}^{\infty} \frac{dz}{(z^2 + 1)^2} \left(1 - \frac{\sin z\hat{r}}{z\hat{r}}\right)$$

$$\equiv -\alpha T \phi_{0}(\hat{r})$$

(47)

and the contribution due to the string term becomes

$$\Im V_{2}(r, T) = 4\sigma T \int_{0}^{\infty} \frac{dz}{m_D^2 (z^2 + 1)^2} \left(1 - \frac{\sin z\hat{r}}{z\hat{r}}\right)$$

$$\equiv 2\sigma T \psi_{0}(\hat{r}),$$

(48)

where the functions, $\phi_{0}(\hat{r})$ and $\psi_{0}(\hat{r})$ at leading-order in $\hat{r}$ are

$$\phi_{0}(\hat{r}) = -\alpha T \left(-\frac{\hat{r}^2}{9}(-4 + 3\gamma_E + 3\log \hat{r})\right)$$

$$\psi_{0}(\hat{r}) = \frac{\hat{r}^2}{6} + \left(-\frac{107 + 60\gamma_E + 60\log(\hat{r})}{3600}\right) \hat{r}^4 + O(\hat{r}^5).$$

(49)

(50)

In the short-distance limit ($\hat{r} \ll 1$), both the contributions, at the leading logarithmic order, reduce to

$$\Im V_{1}(r, T) = -\alpha T \frac{\hat{r}^2}{3} \log(\frac{1}{\hat{r}})$$

(51)

$$\Im V_{2}(r, T) = 2\sigma T \frac{\hat{r}^4}{m_D^2} \frac{\hat{r}^4}{60} \log(\frac{1}{\hat{r}}),$$

(52)

thus the sum of Coulomb and string term gives the full imaginary part:

$$\Im V_{\text{iso}}(r, \xi, T) = -T \left(\frac{\alpha \hat{r}^2}{3} + \frac{\sigma \hat{r}^4}{30m_D^2}\right) \log(\frac{1}{\hat{r}})$$

(53)

One thus immediately observes that for small distances the imaginary part vanishes and its magnitude is larger than the case where only the Coulombic term is considered [62] and thus enhances the width of the resonances in thermal medium.
The imaginary part of the potential, in small-distance limit, is a perturbation to the vacuum potential and thus provides an estimate for the width ($\Gamma$) for a resonance state and can be calculated, in a first-order perturbation, by folding with the unperturbed (1S) Coulomb wavefunction

$$\Gamma_{(\text{iso})} = \left( \frac{4T}{2m_Q^2} + \frac{12\sigma T}{\alpha^2 m_Q^2} \right) m_D^2 \log \frac{\alpha m_Q}{2m_D}. \quad (54)$$

The main features of our results (Fig. 3) are: First the width always increases with the temperature. Secondly the inclusion of non vanishing nonperturbative string term, in addition to the Coulomb term, makes the width larger than the earlier result with the perturbative Coulomb term \cite{74} only and thus the damping of the exchanged gluon in the heat bath provides larger contribution to the dissociation rate and consequently reduce the yield of dileptons in the peak. The effect of nonperturbative term on the width is relatively more on $J/\psi$ than $\Upsilon$ state because the binding of $\Upsilon$ (1S) state is more Coulombic than $J/\psi$ (1S) state. This has far reaching conclusion on their dissociation. Thirdly the width is also affected by the screening scale we chose to regulate the potential, $V(p)$, namely the width with the higher screening scale ($1.4 m_D^{\text{LO}}$) is more than the leading-order result.

We will now study the dissociation in thermal medium with both the real and imaginary part of the potential where someone calculates the dissociation temperature ($T_d$) from the intersection of the binding energies obtained from the real and imaginary part of the potential \cite{37, 58}, respectively whereas others use the conservative criterion on the width of the resonance as: $\Gamma \geq 2B.E. \ [20]$. Although both definitions are physically equivalent but they are numerically different, so we reported both results. For example, $J/\psi$ is dissociated at $2.45 T_c$ obtained from the intersection of binding energies while the condition on width gives much lower temperature ($1.40 T_c$) (Table 1). Correspondingly $\Upsilon$ (1S) is dissociated at $3.40 T_c$ and $3.10 T_c$, respectively. Our results are found relatively higher compared to similar calculation \cite{37, 58}, which may be due to the absence of three-dimensional medium modification of the linear term in their calculation.

**Figure 3:** Decay width of $J/\psi$ (left) and $\Upsilon$ (right) states with and without nonperturbative (string) term in an isotropic medium with the Debye masses in leading-order and the lattice fitted result.
Finally we explore the sensitivity of the screening scale on the dissociation mechanism where the dissociation temperatures computed with the next-to-leading order (1.4 $m_D^{LO}$) Debye mass are found smaller than the leading-order result. For example, $J/\psi$ and $\Upsilon$ are now dissociated 1.33 $T_c$ and 1.91$T_c$, respectively (Table 2).

### 2.3 Potential in anisotropic medium

The space-time evolution of QGP relies on the viscous hydrodynamical treatment where the system assumes a local thermal equilibrium, i.e. close to isotropic in momentum space. However, this assumption breaks down at the earliest time in the collision of two nuclei, due to large momentum-space anisotropies [52, 53, 69]. The degree of anisotropy increases as the shear viscosity increases and thus one must address it while calculating the heavy quark potential in the presence of momentum-space anisotropies. The real-part of the heavy quark potential was first considered in [54] and then the imaginary part was obtained theoretically [56, 57, 70] as well as phenomenologically [55, 37, 58]. The main effect of the anisotropy is to reduce Debye screening which, in turn has the effect that heavy quarkonium states can survive up to higher temperatures.

The works referred above are limited to the medium-modification of the perturbative part only and the nonperturbative string term was assumed to zero. However, the string-tension is non vanishing even at temperatures much beyond the deconfinement point [44, 45, 46], so one should study its effect on the heavy quark potential in anisotropic medium too.

#### 2.3.1 Real Part

In analogy to the isotropic case, we obtain the real-part of the potential in weakly-anisotropic medium [59] from the anisotropic corrections to the (temporal component) real-part of retarded propagator (29)

$$
\Re V_{\text{aniso}}(r, \xi, T) = \int \frac{d^3p}{(2\pi)^{3/2}} (e^{ip\cdot r} - 1) \left( -\sqrt{\frac{2}{\pi}} \frac{\alpha}{p^2} - \frac{4\sigma}{\sqrt{2}\pi p^4} \right) \times 
\left[ \frac{1}{p^2 \left[ (p^2 + m^2_D) \right]} - \frac{\xi m^2_D}{6(p^2 + m^2_D)^2} (3 \cos 2\theta_p - 1) \right]
$$

$$
\equiv \Re V_{1\text{aniso}}(r, \xi, T) + \Re V_{2\text{aniso}}(r, \xi, T),
$$

where $\Re V_{1\text{aniso}}(r, \xi, T)$ and $\Re V_{2\text{aniso}}(r, \xi, T)$ are the medium modifications corresponding to the Coulomb and string term, respectively, are given by

$$
\Re V_{1\text{aniso}}(r, \xi, T) = -\frac{\alpha}{2\pi^2} \int d^3p (e^{ip\cdot r} - 1) \left[ \frac{1}{(p^2 + m^2_D)} - \frac{\xi m^2_D}{6(p^2 + m^2_D)^2} (3 \cos 2\theta_p - 1) \right]
$$

$$
\Re V_{2\text{aniso}}(r, \xi, T) = -\frac{4\sigma}{2\pi^2} \int d^3p (e^{ip\cdot r} - 1) \frac{1}{p^2} \left[ \frac{1}{(p^2 + m^2_D)} - \frac{\xi m^2_D}{6(p^2 + m^2_D)^2} (3 \cos 2\theta_p - 1) \right].
$$

To perform the momentum integration, we use the transformation $\cos \theta_p = \cos \theta_r \cos \theta_{pr} + \sin \theta_r \sin \theta_{pr} \cos \phi_{pr}$, where $\theta_p$ and $\theta_r$ are the angles between $p, n$ and $r, n$, respectively and $\theta_{pr}, \phi_{pr}$ are the angular variables.
Thus the full (real-part) potential in anisotropic medium becomes

\[ \Re V_{1(\text{aniso})}(r, \xi, T) = -\alpha m_D \left[ \frac{e^{-\hat{r}}}{\hat{r}} + 1 + \xi \left[ \frac{(e^{-\hat{r}} - 1)}{6} + \frac{e^{-\hat{r}}}{12} + \frac{e^{-\hat{r}}}{12} \right] \right] \times (1 - 3 \cos^2 \theta_r) \]  

and the string contribution is

\[ \Re V_{2(\text{aniso})}(r, \xi, T) = \frac{2\sigma}{m_D} \left[ \frac{(e^{-\hat{r}} - 1)}{\hat{r}} + 1 + 2\xi \left[ \frac{(e^{-\hat{r}} - 1) + e^{-\hat{r}}}{12} + \frac{e^{-\hat{r}}}{12} \right] \right] + \left( e^{-\hat{r}} \left( \frac{1}{\hat{r}^2} + \frac{5}{12r} + \frac{1}{12r} + \frac{(e^{-\hat{r}} - 1)}{\hat{r}^2} \right) (1 - 3 \cos^2 \theta_r) \right) . \]  

Thus the full (real-part) potential in anisotropic medium becomes

\[ \Re V_{\text{aniso}}(r, \theta_r, T) = \left( \frac{2\sigma}{m_D} - \alpha m_D \right) \frac{e^{-\hat{r}}}{\hat{r}} - \frac{2\sigma}{m_D} + \frac{2\sigma}{m_D} - \alpha m_D \]
\[ + \xi \left( \frac{2\sigma}{m_D} \frac{e^{-\hat{r}}}{\hat{r}} \left[ \frac{e^\hat{r} - 1}{\hat{r}^2} + \frac{5e^\hat{r}}{12} + \frac{e^\hat{r}}{3} - \frac{1}{\hat{r}^2} + \frac{\hat{r}}{1} - \frac{\hat{r}}{12} \right] \right) \]
\[ - \frac{\alpha m_D e^{-\hat{r}}}{\hat{r}} \left[ \frac{e^\hat{r} - 1}{\hat{r}^2} + \frac{5e^\hat{r}}{12} + \frac{e^\hat{r}}{3} - \frac{1}{\hat{r}^2} + \frac{\hat{r}}{1} - \frac{\hat{r}}{12} \right] \]
\[ + \left( \frac{2\sigma}{m_D} \frac{e^{-\hat{r}}}{\hat{r}} \left[ \frac{e^\hat{r} - 1}{\hat{r}^2} + \frac{5e^\hat{r}}{12} + \frac{e^\hat{r}}{3} - \frac{1}{\hat{r}^2} + \frac{\hat{r}}{1} - \frac{\hat{r}}{12} \right] \right) \cos 2\theta_r \]
\[ = \Re V_{\text{iso}}(r, T) + V_{\text{tensor}}(r, \theta_r, T) \]  

Thus the anisotropy in the momentum space introduces an angular ($\theta_r$) dependence, in addition to the interparticle separation ($r$), to the potential, in contrast to the $r$-dependence only in an isotropic medium. The potential becomes stronger with the increase of anisotropy because the (anisotropic) Debye mass $\mu_D(\xi, T)$ (or equivalently angular-dependent Debye mass $\mu(\theta_r, T)$) in an anisotropic medium is always smaller than in an isotropic medium. As a result the screening of the Coulomb and string contribution are less accentuated, compared to the isotropic medium. In particular, the potential for quark pairs aligned in the direction of anisotropy are stronger than the pairs aligned in the transverse direction.

In short-distance limit, the vacuum contribution dominates over the medium contribution even for the weakly anisotropic medium and in long-distance limit, the potential in high temperature approximation results a Coulomb plus a subleading anisotropic contribution:

\[ \Re V_{\text{aniso}}(r, \theta_r, T) \underset{r \gg 1}{=} -\frac{2\sigma}{m_D^2} - \alpha m_D - \frac{5\xi}{12} \frac{2\sigma}{m_D^2} \left( 1 + \frac{3}{5} \cos 2\theta_r \right) \]
\[ \equiv \Re V_{\text{iso}}(r \gg 1, T) + V_{\text{tensor}}(r \gg 1, \theta_r, T) . \]
2.3.2 Binding Energy

The potential thus obtained in anisotropic medium (60), in contrast to the (spherically symmetric) potential in isotropic medium, is non-spherical and so one cannot simply obtain the energy eigen values by solving the radial part of the Schrödinger equation alone because the radial part is no longer sufficient due to the angular dependence in the potential. Other way to understand is that because of the anisotropic screening scale, the wave functions are no longer radially symmetric for $\xi \neq 0$. So one has to solve the potential in three dimension but in the small $\xi$-limit, the non-symmetric component $V_{\text{tensor}}(r, \theta, T)$ is much smaller than the symmetric (isotropic) component $\Re V_{\text{iso}}(r, T)$ and thus can be treated as perturbation.

Therefore, the corrected energy eigen value comes from the solution of Schrödinger equation of the isotropic component by the matrix method plus the first-order perturbation due to the anisotropic component $V_{\text{tensor}}(r, \theta, T)$. However, the approximated form (61) gives an analytical estimate of the binding energy, in weakly-anisotropic medium:

$$E_{\text{bin}} = \left( \frac{m_Q \sigma^2}{m_b^2 n^2} + \alpha m_D \right) + \frac{2 \xi}{3} \frac{m_Q \sigma^2}{m_b^2 n^2},$$

where the first term is the solution of (radial-part) of the Schrödinger equation with the isotropic part ($\Re V_{\text{iso}}(r \gg 1, T)$) and the second term is due to the anisotropic perturbation of the tensorial component ($V_{\text{tensor}}(r \gg 1, \theta, T)$) calculated from the first-order perturbation theory.

The binding energies for $J/\psi$ and $\Upsilon$ state are computed numerically in Fig 5 for different values of anisotropies. The main features are: like isotropic medium, the inclusion of nonperturbative string term makes the quarkonium states more bound in the anisotropic medium too. Secondly the binding of $Q\bar{Q}$ pairs becomes stronger with respect to their isotropic counterpart and increases with the increase of anisotropy because the potential becomes deeper due to the weaker screening. Last but not the least, as the screening scale increases the binding gets weakened even in anisotropic medium.
2.3.3 Imaginary Part

Recently the imaginary part with a momentum-space anisotropy and its effects on the thermal widths of the resonance states have been studied [58, 62, 73, 74] in the weak-coupling regime. The imaginary part of the potential arises because of the singlet-octet transitions induced by the dipole vertex as well as due to the Landau damping in the plasma, i.e., scattering of the gluons with space-like momentum off the thermal excitations in the plasma. We continue the same by including the medium corrections to both non-perturbative part (string term) and perturbative part (Coulombic term) in a weakly anisotropic medium. Like in isotropic medium, we can obtain the imaginary part of the potential by the leading anisotropic correction to the imaginary part of the (temporal component) symmetric propagator as

\[
\Im V_{(\text{aniso})}(r, \xi, T) = -\int \frac{d^3p}{(2\pi)^{3/2}} (e^{ip\cdot r} - 1) \left(-\frac{2}{\pi} \frac{\alpha}{p^2} - \frac{4\sigma}{\sqrt{2}\pi p^4}\right) p^2 \left[-\pi T m_J^2 \frac{2}{p(p^2 + m_J^2)^2}\right.
\]
\[
+ \xi \left[\frac{3\pi T m_J^3}{2p(p^2 + m_J^2)^2} \sin^2 \theta_p - \frac{4\pi T m_J^3}{p(p^2 + m_J^2)^3} (\sin^2 \theta_p - \frac{1}{3})\right]
\]
\[
\equiv \Im V_{1(\text{aniso})}(r, \xi, T) + \Im V_{2(\text{aniso})}(r, \xi, T),
\]

(64)
where $\Im V_{1(\text{aniso})}(r, \xi, T)$ and $\Im V_{2(\text{aniso})}(r, \xi, T)$ are the imaginary contributions corresponding to the Coulombic and linear terms in an anisotropic medium, respectively:

$$\Im V_{1(\text{aniso})}(r, \xi, T) = \frac{\alpha}{2\pi^2} \int d^3p (e^{ip \cdot r} - 1) \left[ \frac{-\pi T m_D^2}{p(p^2 + m_D^2)^2} + \xi \left( \frac{3\pi T m_D^2}{4p(p^2 + m_D^2)^2} \sin^2 \theta_p \right) \right. $$

$$\left. - \frac{2\pi T m_D^4}{p(p^2 + m_D^2)^3} \left( \sin^2 \theta_p - \frac{1}{3} \right) \right] \quad (65)$$

where the functions $\phi_1(\hat{r}, \theta_r)$ and $\phi_2(\hat{r}, \theta_r)$ are

$$\phi_1(\hat{r}, \theta_r) = \frac{\hat{r}^2}{600} \left[ 123 - 90\gamma_E - 90 \log \hat{r} + \cos(2\theta_r) (-31 + 30\gamma_E + 30 \log \hat{r}) \right]$$

$$\phi_2(\hat{r}, \theta_r) = \frac{\hat{r}^2}{90} (-4 + 3 \cos(2\theta_r)) \quad (68)$$

Similarly the imaginary contribution due to the nonperturbative (linear) term can also separated into the isotropic and anisotropic term. The isotropic part is already calculated in Sec.2.2.3 and the anisotropic part is calculated as

$$\Im V_{2(\text{aniso})}(r, \xi, T) = -\frac{2\sigma T}{m_D^2} \xi \left[ \psi_1(\hat{r}, \theta_r) + \psi_2(\hat{r}, \theta_r) \right] \quad , (69)$$
where the function, \( \psi_1(\hat{r}, \theta_r) \) is given by

\[
\psi_1(\hat{r}, \theta_r) = \int \frac{dz}{z(z^2 + 1)^2} \left[ 1 - \frac{3}{2} \left( \frac{\sin(z\hat{r})}{z\hat{r}} + \cos(z\hat{r}) \frac{\cos(z\hat{r})}{z\hat{r}} - \sin(z\hat{r}) \right) \right] \text{ with (70)}
\]

\[
G(\hat{r}, z) = \frac{\hat{r} \cos(z\hat{r}) - \sin(z\hat{r})}{(z\hat{r})^3} \quad (71)
\]

Substituting \( G(\hat{r}, z) \), \( \psi_1(\hat{r}, \theta_r) \) can be decomposed into \( \theta_r \)- dependent and independent terms:

\[
\psi_1(\hat{r}, \theta_r) = \int \frac{dz}{z(z^2 + 1)^2} \left[ 1 - \frac{3}{2} \left( \frac{\sin(z\hat{r})}{z\hat{r}} + \cos(z\hat{r}) \frac{\cos(z\hat{r})}{z\hat{r}} - \sin(z\hat{r}) \right) \right]
+ \frac{3}{2} \left( \frac{\sin(z\hat{r})}{z\hat{r}} + \frac{3 \cos(z\hat{r})}{z\hat{r}} - \frac{3 \sin(z\hat{r})}{z\hat{r}} \right) \frac{\cos^2 \theta_r}{(z\hat{r})^3} \right]
\equiv \psi_1^{(1)}(\hat{r}) + \psi_1^{(2)}(\hat{r}, \theta_r) , \quad (72)
\]

where the functions \( \psi_1^{(1)}(\hat{r}) \) and \( \psi_1^{(2)}(\hat{r}, \theta_r) \) are given by

\[
\psi_1^{(1)}(\hat{r}) = \int \frac{dz}{z(z^2 + 1)^2} \left[ 1 - \frac{3}{2} \left( \frac{\sin(z\hat{r})}{z\hat{r}} + \frac{\cos(z\hat{r})}{z\hat{r}} - \frac{\sin(z\hat{r})}{z\hat{r}} \right) \right]
= \frac{\hat{r}^2}{10} + \frac{(-739 + 420 \gamma_E + 420 \log(\hat{r}))\hat{r}^4}{39200} + O(\hat{r}^3), \quad (73)
\]

and

\[
\psi_1^{(2)}(\hat{r}, \theta_r) = \frac{3}{2} \int \frac{dz}{z(z^2 + 1)^2} \left[ \left( \frac{\sin(z\hat{r})}{z\hat{r}} + \frac{3 \cos(z\hat{r})}{z\hat{r}} - \frac{3 \sin(z\hat{r})}{z\hat{r}} \right) \cos^2 \theta_r \right]
= \frac{3}{2} \int \frac{dz}{z(z^2 + 1)^2} \left[ \left( \frac{\sin(z\hat{r})}{z\hat{r}} + \frac{3 \cos(z\hat{r})}{z\hat{r}} - \frac{3 \sin(z\hat{r})}{z\hat{r}} \right) \cos^2 \theta_r \right]
= \left( -\frac{\hat{r}^2}{20} + \frac{(176 - 105 \gamma_E - 105 \log(\hat{r}))\hat{r}^4}{14700} + O(\hat{r}^5) \right) \cos^2 \theta_r . \quad (74)
\]

The remaining function in the imaginary part of the linear term (69) can similarly be isolated into \( \theta_r \)- dependent and independent terms:

\[
\psi_2(\hat{r}, \theta_r) = -\frac{4}{3} \int \frac{dz}{z(z^2 + 1)^3} \left[ 1 - \frac{3}{2} \left( \frac{2}{3} - \frac{\cos^2 \theta_r}{z\hat{r}} \right) \frac{\sin(z\hat{r})}{z\hat{r}} \right] + (1 - 3 \cos^2 \theta_r)G(\hat{r}, z) \]
= -\frac{4}{3} \int \frac{dz}{z(z^2 + 1)^3} \left[ 1 - 2 \frac{\sin(z\hat{r})}{z\hat{r}} + \frac{3 \cos(z\hat{r})}{z\hat{r}} - \frac{3 \sin(z\hat{r})}{z\hat{r}} \right]
+ 3 \left( \frac{\sin(z\hat{r})}{z\hat{r}} + \frac{3 \cos(z\hat{r})}{z\hat{r}} - \frac{3 \sin(z\hat{r})}{z\hat{r}} \right) \frac{\cos^2 \theta_r}{(z\hat{r})^3} \right]
\equiv \psi_2^{(1)}(\hat{r}) + \psi_2^{(2)}(\hat{r}, \theta_r) , \quad (75)
\]

where the functions \( \psi_2^{(1)}(\hat{r}) \) and \( \psi_2^{(2)}(\hat{r}, \theta_r) \) are

\[
\psi_2^{(1)}(\hat{r}) = \frac{4}{3} \int \frac{dz}{z(z^2 + 1)^3} \left( 1 - 2 \frac{\sin(z\hat{r})}{z\hat{r}} + \frac{3 \cos(z\hat{r})}{z\hat{r}} - \frac{3 \sin(z\hat{r})}{z\hat{r}} \right)
= \frac{4}{3} \left[ \frac{7\hat{r}^2}{120} - \frac{11\hat{r}^4}{3360} + O(\hat{r}^5) \right] \quad (76)
\]
and

\[ \psi^{(2)}(\hat{r}, \theta_r) = -4 \int \frac{dz}{z(z^2 + 1)^3} \left( \frac{\sin z\hat{r}}{z\hat{r}} + \frac{3\cos(z\hat{r})}{(z\hat{r})^2} - \frac{3\sin(z\hat{r})}{(z\hat{r})^3} \right) \cos^2 \theta_r \]

\[ = -4 \left\{ \frac{\hat{r}^2}{60} + \frac{\hat{r}^4}{840} + O(\hat{r}^5) \right\} \cos^2 \theta_r \]

\[ (77) \]

So the functions \( \psi_1(\hat{r}, \theta_r) \) and \( \psi_2(\hat{r}, \theta_r) \) can be written as

\[ \psi_1(\hat{r}, \theta_r) = \frac{\hat{r}^2}{10} + \left( \frac{-739 + 420\gamma_E + 420 \log(\hat{r})}{39200} \hat{r}^2 \right) \cos^2 \theta_r \]

\[ + \left( \frac{-\hat{r}^2}{20} \left( \frac{176 - 105\gamma_E - 105 \log(\hat{r})}{14700} \right) \hat{r}^4 \right) \cos^2 \theta_r \]

\[ (78) \]

\[ \psi_2(\hat{r}, \theta_r) = -4 \left\{ \frac{7\hat{r}^2}{120} + \frac{11\hat{r}^4}{3360} + O(\hat{r}^5) \right\} \]

\[ -4 \left\{ \frac{\hat{r}^2}{60} + \frac{\hat{r}^4}{840} + O(\hat{r}^5) \right\} \cos^2 \theta_r \]

\[ (79) \]

respectively and \( \gamma_E \) is the Euler-Gamma constant.

Finally the short and long-distance contributions, in the leading logarithmic order

\[ \Im V_{1(aniso)}(r, \theta_r, T) = -\alpha T \hat{r}^2 \log(\frac{1}{\hat{r}}) \left( \frac{1}{3} - \frac{2}{3} \cos 2\theta_r \right) \]

\[ (80) \]

\[ \Im V_{2(aniso)}(r, \theta_r, T) = -2\sigma T \frac{\hat{r}^4}{m_D^2} \log(\frac{1}{\hat{r}}) \left( \frac{1}{3} - \frac{2}{14} \cos 2\theta_r \right) \]

\[ (81) \]

gives the full imaginary part in anisotropic medium

\[ \Im V_{aniso}(r, \theta_r, T) = -T \left( \frac{\alpha\hat{r}^2}{3} + \frac{\sigma\hat{r}^4}{30m_D^2} \right) \log(\frac{1}{\hat{r}}) \]

\[ + \xi T \left( \frac{\alpha\hat{r}^2}{5} + \frac{3\sigma\hat{r}^4}{140m_D^2} \right) - \cos^2 \theta_r \left( \frac{\alpha\hat{r}^2}{10} + \frac{\sigma\hat{r}^4}{70m_D^2} \right) \log(\frac{1}{\hat{r}}) \]

\[ (82) \]

which is found to be smaller than the isotropic medium and decreases with the increase of anisotropy.
| Method          | State | $\xi = 0.0$ | $\xi = 0.3$ | $\xi = 0.6$ |
|-----------------|-------|-------------|-------------|-------------|
| Re B.E. = Im B.E. | $J/\psi$ | 2.45        | 2.46        | 2.47        |
|                 | $\Upsilon$ | 3.40        | 3.45        | 3.46        |
| $\Gamma = 2\text{B.E.}$ | $J/\psi$ | 1.40        | 1.46        | 1.54        |
|                 | $\Upsilon$ | 3.10        | 3.17        | 3.26        |

Table 1: Dissociation temperatures of $J/\psi$ and $\Upsilon$ states for different anisotropies with the Debye mass in leading-order and the running coupling up to one-loop.

| Method          | State | $\xi = 0.0$ | $\xi = 0.3$ | $\xi = 0.6$ |
|-----------------|-------|-------------|-------------|-------------|
| Re B.E. = Im B.E. | $J/\psi$ | 1.33        | 1.34        | 1.35        |
|                 | $\Upsilon$ | 1.91        | 1.93        | 1.94        |
| $\Gamma = 2\text{B.E.}$ | $J/\psi$ | 1.02        | 1.06        | 1.12        |
|                 | $\Upsilon$ | 1.88        | 1.92        | 2.02        |

Table 2: The same as Table 1 but the lattice parametrized form of Debye mass ($1.4 m_D^{1/2}$) has been used.

Like in isotropic medium, in weakly anisotropic medium too, the imaginary part is found to be a perturbation to the potential and thus provides an estimate for the (thermal) width for a particular resonance state:

$$
\Gamma_{\text{(aniso)}} = \int d^3r |\Psi(r)|^2 \left[ \frac{\alpha T r^2 \log \left( \frac{1}{r} \right)}{\frac{1}{2} - \frac{2 - \cos 2\theta_r}{10}} \right.
\left. + \frac{2\sigma T}{m_D^2} r^4 \log \left( \frac{1}{r} \right) \frac{1}{20} \left( \frac{1}{3} - \frac{2 - \cos 2\theta_r}{14} \right) \right]
= T \left( \frac{1}{\alpha m_Q^2} + \frac{12\sigma T}{\alpha^2 m_Q^4} \right) \left( 1 - \frac{\xi}{2} \right) m_D^2 \log \frac{\alpha m_Q}{2m_D},
$$

which shows that the width in anisotropic medium becomes smaller than isotropic medium and gets narrower with the increase of anisotropy, just opposite to the binding energies. This is due to the fact that the Debye mass decreases in the anisotropic medium because the effective local parton density around a test (heavy) quark is smaller compared to isotropic medium.

We have now computed the dissociation temperatures at different anisotropies where $J/\psi$ is dissociated at 2.46 $T_c$ and 2.49 $T_c$, respectively for $\xi = 0.3$ and 0.6, respectively, obtained from the intersection of binding energies whereas $\Upsilon$ are correspondingly dissociated at 3.45 $T_c$ and 3.46 $T_c$, respectively (Table 1). Thus the presence of anisotropy enhances the dissociation point to the resonances. Like isotropic medium, we also computed the dissociation temperatures from the criterion on width and found the temperatures become smaller. For example, $J/\psi$ is now dissociated at 1.46 $T_c$ and 1.54 $T_c$ and $\Upsilon$ is dissociated at 3.17$T_c$ and 3.26 $T_c$, for the same anisotropies.

3 Conclusion

We have investigated the properties of charmonium and bottomonium states through the in-medium modifications to both perturbative and nonperturbative of the Cornell potential, not its perturbative term alone as usually done in the literature. For this purpose we have derived both the real and imaginary part of
the potential within the framework of real-time formalism, in both isotropic and anisotropic medium. In isotropic medium, the inclusion of the linear term, in addition to the Coulomb term, makes the real part of the potential more attractive. So, as a consequence the quarkonium states become more bound compared to the medium modification to the Coulomb term alone. Moreover the string term affects the imaginary part too where its magnitude is increased by the string contribution. As a result, the (thermal) width of the states are broadened due to the presence of string term and makes the competition between the screening and the broadening due to damping interesting which plays an important role in the dissociation mechanism. With these cumulative observations, we studied the dissociation in a medium where a resonance is said to be dissolved in a medium [27, 56] when its binding energy decreases with temperature and becomes equal to its width. We have found that the quarkonium states are dissociated at higher temperature compared to the medium-consideration of the Coulomb term only.

We have then extended our exploration of quarkonium in a medium which exhibits a local anisotropy in the momentum space. This may arise due to the rapid expansion in the beam direction compared to its transverse direction, at the early stage of the evolution in ultra-relativistic heavy-ion collisions. For that, we have first revisited the anisotropic corrections to the retarded, advanced and symmetric propagators through their self-energies in the hard-loop resummation technique and apply these results to calculate the medium-corrections to the perturbative and nonperturbative term of the Cornell potential. We are however restricted to a medium close to equilibrium because although the system was initially anisotropic but by the time quarkonium resonances are formed in plasma ($t_F = \gamma \tau_F$, $\tau_F$ is the formation time in the rest frame of quarkonium), the plasma becomes almost isotropic.

The effect of nonvanishing nonperturbative term on the quarkonium properties, as seen earlier, remains the same even in the presence of momentum anisotropy. However, the anisotropy behaves as an additional handle to decipher the properties of quarkonium states, namely, in anisotropic medium, the binding of $Q\bar{Q}$ pairs gets stronger with respect to their isotropic counterpart because the potential becomes deeper with the increase of anisotropy. This is due to the fact that the (effective) Debye mass in anisotropic medium is always smaller than in isotropic medium. As a result the screening of the Coulomb and string contributions is less accentuated and thus quarkonium states are bound more strongly than in isotropic medium. The overall observation is that the dissociation temperature increases with the increase of anisotropy. For example, $J/\psi$ is dissociated at 2.45 $T_c$, 2.46 $T_c$, and 2.49 $T_c$ for the anisotropies $\xi = 0.0$, 0.3, and 0.6, respectively. Similarly, $\Upsilon$ is dissociated at 3.40 $T_c$, 3.45 $T_c$, and 3.46 $T_c$ for $\xi = 0.0$, 0.3, and 0.6, respectively.

Our results are found relatively higher compared to similar calculation [37, 58], which may be due to the absence of three-dimensional medium modification of the linear term in their calculation. In fact, one-dimensional Fourier transform of the Cornell potential yields the similar form used in the lattice QCD in which one-dimensional color flux tube structure was assumed [47]. However, at finite temperature that may not be the case since the flux-tube structure may expand in more dimensions [48]. Therefore, it would be better to consider the three-dimensional form of the medium modified Cornell potential which has been done exactly in the present work.
In brief, the properties of quarkonium states are affected by the inclusion of the non-perturbative (string) term in the potential, in addition to the anisotropic medium effects.
