In a recent paper we claimed that there are no slowly rotating, stationary, axisymmetric black holes in the infrared limit of Hořava-Lifshitz gravity, provided that they are regular everywhere apart from the central singularity. Here we point out a subtlety in the relation between Einstein-aether theory and the infrared limit of Hořava-Lifshitz gravity which was missed in our earlier derivation and drastically modifies our conclusion: our earlier calculations (which are otherwise technically correct) do not really imply that there are no slowly rotating black holes in Hořava-Lifshitz gravity, but that there are no slowly rotating black holes in the latter that are also solutions of Einstein-aether theory and vice versa. That is, even though the two theories share the static, spherically symmetric solutions, there are no slowly rotating black holes that are solutions to both theories. We proceed to generate slowly rotating black-hole solutions in the infrared limit of Hořava-Lifshitz gravity, and we show that the configuration of the foliation-defining scalar remains the same as in spherical symmetry, thus these black holes are expected to possess a universal horizon.

I. INTRODUCTION

In Ref. [1] we considered slowly rotating, stationary, axisymmetric black holes which are regular everywhere apart from the central singularity, and we claimed that such solutions do not exist in the infrared limit of Hořava-Lifshitz (HL) gravity. This claim is actually incorrect. As we explain below, our derivation was implicitly using the relation between the infrared limit of HL gravity and Einstein-aether theory (æ-theory). However, a subtle point in this relation has been missed, which effectively implies that we were implicitly requiring our solutions to be solutions of æ-theory with a hypersurface-orthogonal aether configuration. The purpose of this note is threefold: (a) to clarify how this oversight affected our calculations; (b) to reinterpret our existing results, given that the calculations of Ref. [1] are actually technically correct and lead to some meaningful statements about æ-theory; (c) to correct our claims about HL gravity, point out that there are indeed slowly rotating black holes in Hořava-Lifshitz gravity, but that there are no slowly rotating black holes in Hořava-Lifshitz gravity, and we show that the configuration of the foliation-defining scalar remains the same as in spherical symmetry, thus these black holes are expected to possess a universal horizon.

II. A SUBTLETY IN THE RELATION BETWEEN HL GRAVITY AND Æ-THEORY

Einstein-aether theory is described by the action

$$S_\text{æ} = \frac{M_\text{æ}}{2} \int d^4x \sqrt{-g} \left( -R + M^\alpha_\beta_{\mu \nu} \nabla_\alpha u^\mu \nabla_\beta u^\nu \right), \quad (1)$$

where $g$ is the determinant of the metric $g_{\mu \nu}$, $\nabla_\mu$ is the associated covariant derivative, $R$ is the Ricci scalar of this metric,

$$M^\alpha_\beta_{\mu \nu} \equiv c_1 g^\alpha_\beta g_{\mu \nu} + c_2 \delta^\alpha_\mu \delta^\beta_\nu + c_3 \delta^\alpha_\nu \delta^\beta_\mu + c_4 u^\alpha u^\beta g_{\mu \nu}, \quad (2)$$

c_1$ to $c_4$ are dimensionless parameters, and the aether $u^\mu$ is assumed to satisfy the constraint

$$u^\mu u_\mu = 1. \quad (3)$$

This constraint can be enforced either by considering restricted variations of the action which respect it, or by adding to the action explicitly the Lagrange multiplier $\xi (u^\mu u_\mu - 1)$.

It has been shown in Ref. [2] that æ-theory is equivalent to the infrared limit of HL gravity if the aether is assumed to be hypersurface orthogonal before the variation. Locally, hypersurface orthogonality can be imposed through the condition

$$u_\mu = \frac{\partial_\mu T}{\sqrt{g^{\alpha \beta} \partial_\alpha T \partial_\beta T}}. \quad (4)$$

where $T$ is a scalar field that defines a foliation. Choosing $T$ as the time coordinate, one selects the preferred foliation of HL gravity, and the action (1) reduces to the action of the infrared limit of HL gravity, whose Lagrangian is denoted as $L_2$ and given in Eq. (2) of Ref. [1], and the correspondence of the parameters of the two theories is given in Eq. (6) of the same paper.

We consider now the corresponding field equations. Obviously, the equations of HL gravity will not be the equations of æ-theory with the aether expressed as in Eq. (4), as the equivalence only holds if the hypersurface-orthogonality condition is imposed at the level of the action.
Let us consider the variation. Adding to action (1) the Lagrange multiplier in order to enforce the unit constraint leads to

\[ S = S_x + \int d^4x \sqrt{-g} \zeta (u^\mu u_\mu - 1), \quad (5) \]

and then variation yields

\[ \delta S = \int d^4x \sqrt{-g} \left[ (E_{\mu \nu} + \xi u_\mu u_\nu - \frac{1}{2} g_{\mu \nu} \zeta (u^4 u_\lambda - 1)) \delta g^{\mu \nu} + (\mathcal{A}^{\mu} + 2 \xi u^{\mu}) \delta u_\mu + (u^4 u_\lambda - 1) \delta \zeta \right], \quad (6) \]

where

\[ E^{\mu \nu} = \frac{\delta S_x}{\delta g^{\mu \nu}}, \quad \mathcal{A}^{\mu} = \frac{\delta S_x}{\delta u_\mu}. \quad (7) \]

Then the field equations are

\[ E_{\mu \nu} + \xi u_\mu u_\nu - \frac{1}{2} g_{\mu \nu} \zeta (u^4 u_\lambda - 1) = 0, \quad (8) \]

\[ \mathcal{A}^{\mu} + 2 \xi u^{\mu} = 0, \quad (9) \]

\[ u^4 u_\lambda = 1, \quad (10) \]

being the æ-theory field equation for the metric and the aether, respectively. Contracting Eq. (9) with \( u_\mu \) and using the unit constraint, the equation can be rewritten as

\[ E_{\mu \nu} - \frac{1}{2} \mathcal{A}^{\lambda} u_\lambda u_\mu u_\nu = 0, \quad (11) \]

\[ \mathcal{A}^{\mu} - \mathcal{A}^{\nu} u_\nu u_\mu = 0, \quad (12) \]

\[ u^4 u_\lambda = 1. \quad (13) \]

These are the exact same equations one would obtain if, instead of the Lagrange multiplier, one had performed a restricted variation that implies the unit constraint (as in Ref. [2]).

If the hypersurface-orthogonality condition is imposed at the level of the action then the variation of \( u_\mu \) has to be expressed in terms of \( \delta T \) and \( \delta g^{\mu \nu} \), i.e.,

\[ \delta u_\mu = - \frac{1}{2} u_\mu u_\nu u_\lambda \delta g^{\nu \lambda} + \frac{1}{\sqrt{g^{\alpha \beta} \partial_\alpha T \partial_\beta T}} (\delta g^{\nu \mu} - u^{\nu} u_\mu) \partial_\nu \sqrt{g} \partial T. \quad (14) \]

So, for (covariantized) HL gravity or hypersurface orthogonal æ-theory, one has

\[ \delta S_{\text{h.o.}} = \int \sqrt{-g} (E_{\mu \nu} \delta g^{\mu \nu} + A^{\lambda} \delta u_\lambda) \]

\[ = \int \sqrt{-g} \left[ (E_{\mu \nu} - \frac{1}{2} A^{\lambda} u_\lambda u_\nu) \delta g^{\mu \nu} - \nabla_\nu \left( \frac{1}{\sqrt{g^{\alpha \beta} \partial_\alpha T \partial_\beta T}} (\delta g^{\nu \mu} - u^{\nu} u_\mu) A^{\mu} \right) \delta T \right], \quad (15) \]

which leads to the equations

\[ E_{\mu \nu} - \frac{1}{2} A^{\lambda} u_\lambda u_\nu = 0, \quad (16) \]

\[ \nabla_\nu \left( \frac{1}{\sqrt{g^{\alpha \beta} \partial_\alpha T \partial_\beta T}} (\delta g^{\nu \mu} - u^{\nu} u_\mu) A^{\mu} \right) = 0. \quad (17) \]

The unit constraint is automatically satisfied, and this is why it is not present in the action or the field equations.

It should be clear then that Eq. (16) is identical to Eq. (11) and hence, if one just starts with the æ-theory metric field equation and just imposes that the aether is given by Eq. (4), then one obtains the HL gravity metric field equation. Obviously, the aether equation (12) is different than the equation of motion for \( T \), Eq. (17).\(^1\)

Above we performed the variation keeping \( u_\mu \) fixed in æ-theory. Things become much more subtle if one attempts to keep \( u^\mu \) fixed instead. In particular, starting from Eq. (6) and taking into account that

\[ \delta u_\mu = g_{\mu \nu} \delta u^\nu - u^\nu g_{\nu \lambda} \delta g^{\nu \lambda}, \quad (18) \]

one has

\[ \delta S_x = \int \sqrt{-g} \left[ (E_{\mu \nu} - \mathcal{A}^{\lambda} u_\lambda) \delta g^{\mu \nu} - \left( \xi u_\mu u_\nu + \frac{1}{2} g_{\mu \nu} \zeta (u^4 u_\lambda - 1) \right) \delta g^{\mu \nu} + (\mathcal{A}^{\mu} + 2 \xi u^{\mu}) \delta u^\mu + (u^4 u_\lambda - 1) \delta \zeta \right], \quad (19) \]

where \( E_{\mu \nu} \) and \( A^{\mu} \) are the same quantities as above. Then the equations are

\[ E_{\mu \nu} - \mathcal{A}(\mu u_\nu) = \xi u_\mu u_\nu - \frac{1}{2} g_{\mu \nu} \zeta (u^4 u_\lambda - 1) = 0, \quad (20) \]

\[ \mathcal{A}^{\mu} + 2 \xi u_\mu = 0, \quad (21) \]

\(^1\)Actually, it can be shown that diffeomorphism invariance (or the contracted Bianchi identity) implies that Eq. (17) follows directly from the Einstein equations (16) [2].
black holes in HL gravity is not supported. So, in the rest of the paper we readdress the question of finding slowly rotating solutions in HL gravity.

As discussed in Ref. [1] the most general ansatz for the metric and $u_\mu$ for a slowly rotating, stationary, axisymmetric black hole are without loss of generality $^2$

$$ds^2 = f(r)dt^2 - \frac{B(r)}{f(r)}dr^2 - r^2(d\theta^2 + \sin^2 \theta d\phi^2)$$

$$+ \epsilon r^2 \sin^2 \theta \Omega(r, \theta)dt d\phi + O(\epsilon^2),$$

$$u = 1 + \frac{fA^2}{2A}dr + \frac{B}{2A} \left(1 - A^2\right)dr + O(\epsilon^2),$$

where $\epsilon$ is the book-keeping parameter of the expansion in the rotation, and $A(r), B(r),$ and $f(r)$ are given by the static, spherically symmetric seed solutions (see Ref. [4]). Note in particular that hypersurface orthogonality implies $u_\varphi = 0$ [at least to $O(\epsilon)$] [1].

In Ref. [1] we found it convenient to perform a field redefinition to the spin-0 metric $g_{\alpha \beta} = g_{\alpha \beta} + (s_0^2 - 1)u_\alpha u_\beta$ ($s_0$ being the speed of the spin-0 mode) and to the rescaled aether vector $u^\alpha = s_0^{-1}u^\alpha$ [6] and perform the analysis in terms of the redefined fields. The analysis for HL gravity actually turns out to be slightly simpler in the original variables $g_{\alpha \beta}$ and $u_\mu$, so we will avoid the field redefinitions here. The key difference from the analysis of Ref. [1] is the issue discussed above. As a result, the $r \phi$ and $t \phi$ components of the Einstein equations get modified and become

$$k_0 \Omega + \frac{c_{13} (A^4 f^2 - 1)}{8r^2 A^2 B f} (\partial_\theta^2 \Omega + 3 \cot \theta \partial_\theta \Omega) = 0,$$

$$(\partial_\theta^2 \Omega + 3 \cot \theta \partial_\theta \Omega) \left(\frac{c_{13} A^4 f^2 + 2 A^2 (c_{13} - 2)f + c_{13}}{8A^2 f}\right)$$

$$+ \frac{q_0 \Omega - \frac{r(c_{13} - 1)f(rB' - 4B)\partial_\theta \Omega}{2B^3}}{2B^2} = 0,$$

which replace Eqs. (12) and (13) of our paper. Equation (11) of Ref. [1], which is the $\theta \varphi$ component of the Einstein equations, instead remains unchanged at linear order in $\epsilon$ and is still given by

$$\frac{c_{13}}{8r^3 A^2 B f^2} \left[f[2\partial_\theta \Omega(r, \theta)(A - rA') + rA\partial_r \partial_\theta \Omega(r, \theta)]ight.$$

$$- f^3 A^4 \left[2(rA' + A)\partial_\theta \Omega(r, \theta) + rA\partial_r \partial_\theta \Omega(r, \theta)\right]$$

$$- rA f^2 \partial_\theta \Omega(r, \theta)(1 + A^4 f^2)\right] = 0.$$  

---

$^2$Here $u_\mu$ is given in terms of $T$ by Eq. (4) but it is still more convenient to discuss the ansatz in terms of $u_\mu$. 

---

**III. REINTERPRETATION OF EARLIER RESULTS**

When the aether is hypersurface orthogonal, Eqs. (16) and (23) differ only by terms that vanish when the aether’s equation, Eq. (24), is satisfied. This implies that by considering in Ref. [1] the system of Eqs. (23), (4), and (17), we effectively considered solutions of $\varphi$-theory for which the aether is hypersurface orthogonal (at the level of the solution). Therefore, our earlier results imply that no such solutions exist, and $\varphi$-theory can only admit slowly rotating black-hole solutions where the aether is not hypersurface orthogonal. In HL gravity, instead, $u_\mu$ is by construction a hypersurface orthogonal vector. This implies that, even though the two theories share the static, spherically symmetric black-hole solutions [1,3], they do not share any slowly rotating solution.

Another interesting implication of the fact that $\varphi$-theory does not admit slowly rotating solutions where the aether is hypersurface orthogonal is that slowly rotating black-hole spacetimes in $\varphi$-theory do not have a preferred foliation (but just a preferred frame locally). The existence of the universal horizons found in Refs. [4,5] for static, spherically symmetric black holes appears to be related with the existence of a preferred foliation.

**IV. SLOWLY ROTATING BLACK HOLES IN HL GRAVITY**

Having reinterpreted the results of Ref. [1], it should now be clear that the claim that there are no slowly rotating
(Also, note that the equation of motion of \( T \), Eq. (17), is identically satisfied at linear order in \( \epsilon \)).

Just as in Ref. [1], here \( k_0 \) and \( q_0 \) are complicated functions of the couplings \( c_i \), as well as of \( A, f, \) and \( B \) and their derivatives, but they must evaluate identically to zero when one uses the spherically symmetric static solution, because \( \Omega = \text{const} \) must be a solution to the field equations [1].

Combining Eqs. (29) and (30), we then immediately obtain

\[
- \frac{r(rB' - 4B)\partial_t \Omega}{2B^3} + \frac{r\partial_r^2 \Omega}{2B^2} = 0,
\]

while from Eq. (31), as in Ref. [1], one can conclude that if the black-hole horizon is to be regular and located at \( r = r_H \), one must have \( \Omega(r_H, \theta) = \text{constant} \). Alternatively, one can observe that \( \Omega(r, \theta) = \Omega(r) \) is the only solution to Eq. (29) that is regular at the poles \( \theta = 0, \pi \).

We can then integrate Eq. (32) and obtain

\[
\Omega(r, \theta) = \Omega(r) = -12J \int_{r_H}^{r} \frac{B(\rho)}{\rho^2} d\rho + \Omega_0,
\]

where \( J \) and \( \Omega_0 \) are integration constants. In particular, because with asymptotically flat boundary conditions one has \( B \sim 1 \) far from the black hole, a comparison to the slowly rotating Kerr metric highlights that \( J \) plays the role of the spin of the black hole, while \( \Omega_0 \) can be eliminated from the metric with a coordinate change \( \phi' = \phi - \Omega_0 t/2 \).

V. CONCLUSIONS

Our claim, in Ref. [1], that no slowly rotating regular black-hole solutions exist in HL gravity was incorrect. Such solutions actually exist and are given by Eq. (33), as our amended analysis indicates. It goes beyond the scope of this manuscript to study the characteristics of these slowly rotating black holes, their deviations from the slowly rotating Kerr spacetime, and any related astrophysical implications. We will address this question in a separate publication. It is, however, obvious, that the existence of these solutions implies that there is no \textit{a priori} tension between the prediction of HL gravity and astrophysical evidence for the existence of spinning black holes, in contrast with our previous claim.

It is worth noting that the configuration of the foliations defining scalar \( T \) (or \( u_\mu \)) in these solutions receives no correction at first order in the rotation, and hence it is effectively the same as in their spherically symmetric seed solution. Hence, we expect these solutions to possess a universal horizon.

The results found in Ref. [1], when appropriately reinterpreted, imply that the slowly rotating solutions of HL gravity are not solutions of æ-theory and that the latter has no slowly rotating solution with a hypersurface-orthogonal aether configuration. Hence, æ-theory does not have slowly rotating black holes with a preferred foliation. Even though the two theories share the static, spherically symmetric, asymptotically flat solutions, they do not share slowly rotating solutions.
