(Received 22 June 2018; published 8 November 2018)

We study the theoretical and phenomenological constraints imposed on the scalar sector of the gauged two Higgs doublet model proposed recently as a variant of the popular inert Higgs doublet model of dark matter. The requirements of tree-level vacuum stability and perturbative unitarity in the scalar sector are analyzed in detail. Furthermore, taking into account the constraints from the 125 GeV Higgs boson measurements at the Large Hadron Collider, we map out the allowed ranges for the fundamental parameters of the scalar potential in the model.

DOI: 10.1103/PhysRevD.98.095006

I. INTRODUCTION

Despite the plentiful and cogent evidences of dark matter (DM) from astrophysical and cosmological observations over several decades, the identity of DM is still unknown. Whether the solution should reside on the particle physics side or belong to the pure gravity doctrine is not settled. Perhaps this dilemma will not be resolved anytime soon and will continue baffling us for a while. On the other hand, after the monumental discovery of the 125 GeV Higgs boson [1–5], where the neutral component of the second Higgs doublet can be a DM candidate, while in G2HDM the whole neutral component of H2 can be a DM candidate.

Vacuum stability comes from the requirement that the potential has to be bounded from below, while perturbative unitarity demands the amplitudes of all scattering processes in the scalar sector to lie within the unitarity circle.
In G2HDM, the VEVs of various scalars in the extended Higgs sector will induce complicated mixings among the scalars in the flavor basis. In particular, the discovered 125 GeV boson at the LHC is in general a linear combination of the three neutral components of $H_1$, $\Phi_H$ and $\Delta_H$, where $\Phi_H$ and $\Delta_H$ are the $SU(2)_R$ doublet and triplet respectively. These extra scalars are necessarily introduced in G2HDM for various phenomenological reasons, as explained in detail in [13]. Only in the absence of mixings, would the neutral component of $H_1$ be identified as the observed 125 GeV Higgs boson. As a result, we have to include these mixing effects when imposing the constraints from the measurements of the Higgs boson mass and the diphoton signal strength. The contributions to the diphoton final state from the charged Higgs bosons and new heavy fermions in G2HDM will be carefully scrutinized. There are also mixings between $H^0_2$, $G^0_2$ and $\Delta_m$, the lower components of $H_2$, $\Phi_H$ and $\Delta_H$ respectively, rendering the analysis of DM physics more involved. We will discuss the extended scalar sector of G2HDM in more detail in the next section. However, the thorough study of DM phenomenology in G2HDM will be carried out in a separate work.

The content of the paper is laid out as follows. In Sec. II, we review some crucial features of the G2HDM, with a thorough study of DM phenomenology in G2HDM will be carried out in a separate work. We review some crucial features of the G2HDM, with a thorough study of DM phenomenology in G2HDM will be carried out in a separate work. In Sec. II, we review some crucial features of the G2HDM, with a thorough study of DM phenomenology in G2HDM will be carried out in a separate work.

There are different ways of introducing new heavy fermions in the model but we choose a simplest realization: the heavy fermions together with the SM right-handed fermions comprise $SU(2)_R$ doublets, while the SM left-handed doublets are singlets under $SU(2)_R$. We note that heavy right-handed neutrinos paired up with a mirror charged leptons forming $SU(2)_L$ doublets was suggested before in [20]. To render the model anomaly-free, four additional chiral (left-handed) fermions for each generation, all singlets under both $SU(2)_L$ and $SU(2)_R$, are included. For the Yukawa interactions that couple the fermions to scalars in G2HDM, we refer our readers to [13] for more details.

To avoid some unwanted pieces in the scalar potential and construct gauge invariant Yukawa couplings, we require the matter fields to carry extra $U(1)_X$ charges. Thus the complete gauge groups in G2HDM consist of $SU(3)_c \times SU(2)_L \times U(1)_Y \times SU(2)_R \times U(1)_X$. Apart from the matter content of G2HDM summarized in Table I,\(^\dagger\) there also exist the gauge bosons corresponding to the SM and the extra gauge groups.

The salient features of G2HDM are: (i) it is free of gauge and gravitational anomalies; (ii) renormalizable; (iii) without resorting to the previous ad-hoc $Z_2$ symmetry, an inert Higgs doublet $H_2$ can be naturally realized, providing a DM candidate; (iv) due to the gauge symmetries,\(^\ddagger\) dangerous flavor-changing neutral currents vanish at tree level for the SM sector; (v) the VEV of the triplet can trigger $SU(2)_L$ symmetry breaking while that of $\Phi_H$ provides a

\(\dagger\)We note that $u^H_L$, $d^H_L$, $e^H_L$, $\nu^H_L$ were denoted as $\chi^v$, $\chi^d$, $\chi^e$, respectively in [13].

\(\ddagger\)For using Abelian $U(1)$ symmetry to avoid flavor-changing neutral currents in 2HDM at tree level, see e.g., [21,22].
mass to the new fermions through $SU(2)_H$-invariant Yukawa couplings; etc.

**B. Higgs potential**

The Higgs potential invariant under both $SU(2)_L \times U(1)_Y$ and $SU(2)_H \times U(1)_X$ can be decomposed into four different terms as

$$V_T = V(H) + V(\Phi_H) + V(\Delta_H) + V_{\text{mix}}(H, \Delta_H, \Phi_H),$$

with

$$V(H) = \mu_1^2(H^a H^a) + \lambda_2 \left(\frac{1}{2} H^a H^a H^a H^a\right),$$

$$V(\Phi_H) = \mu_0^2(\Phi_H \Phi_H) + \lambda_3 \left(\frac{1}{2} \Phi_H \Phi_H \Phi_H \Phi_H\right),$$

where $(\alpha, \beta, \gamma, \delta)$ and $(i, j)$ refer to the $SU(2)_H$ and $SU(2)_L$ indices respectively, all of which run from one to two, and $H^a = H^a$.}

$$V(\Phi_H) = \mu_3^2(\Phi_1^1 \Phi_1^2 + \Phi_2^1 \Phi_2^2) + \lambda_4 (\Phi_1^1 \Phi_1^2 + \Phi_2^1 \Phi_2^2),$$

with $\Phi_H = (\Phi_1^1 \Phi_2^2)^T$.

$$V(\Delta_H) = -\mu_5^2 \text{Tr}(\Delta_H^2) + \lambda_5 (\text{Tr}(\Delta_H^2))^2,$$

$$= -\mu_5^2 \left(\frac{1}{2} \Delta_H^2 + \Delta_m \Delta_m\right) \left(\frac{1}{2} \Delta_H^2 + \Delta_m \Delta_m\right),$$

where

$$\Delta_H = \left(\begin{array}{cc} \Delta_1/2 & \Delta_p/\sqrt{2} \\ \Delta_m/\sqrt{2} & -\Delta_3/2 \end{array}\right) = \Delta_H^\dagger$$

and finally the mixed term

$$V_{\text{mix}}(H, \Delta_H, \Phi_H)$$

$$= +M_{\Delta H}(H^\dagger \Delta_H H) - M_{\Phi \Delta}(\Phi_1^1 \Phi_1^2 \Phi_H) + \lambda_{\Delta}(H^\dagger H^\dagger \Delta_H H) + \lambda_{\Phi \Delta}(\Phi_1^1 \Phi_1^2 \Phi_H)(\Phi_1^1 \Phi_1^2 \Phi_H)$$

In terms of the component fields of $H$, $\Delta_H$ and $\Phi_H$, the mixed potential term $V_{\text{mix}}(H, \Delta_H, \Phi_H)$ reads

$$V_{\text{mix}}(H, \Delta_H, \Phi_H) = +M_{\Delta H}(\text{Tr}(\Delta_H^2)) + \lambda_{\Delta}(H^\dagger H^\dagger \Delta_H H) + \lambda_{\Phi \Delta}(\Phi_1^1 \Phi_1^2 \Phi_H)(\Phi_1^1 \Phi_1^2 \Phi_H)$$

One can further substitute the component fields of the two doublets $H_1$ and $H_2$ into Eq. (7). However the resulting expression is tedious and not illuminating, and so will not be shown here.

Before moving to the next subsection on spontaneous symmetry breaking and minimization of the potential, we would like to make some general comments regarding the G2HDM potential.

---

3. Here, we consider renormalizable terms only. In addition, while the $SU(2)_H$ multiplication is explicitly shown, the $SU(2)_L$ multiplication is implicit and suppressed.

4. We should point out that the $\lambda_H$ term in $V(H)$ was missing in earlier studies [13,14] and $V(H)$ contains just three terms (1 mass term and 2 quartic terms) as compared to 8 terms (3 mass terms and 5 quartic terms) in general 2HDM [1].

5. We note that the $\lambda_H$ term in (6) was not included in the original work [13]. Also another invariant operator $(\Phi_1^1 \Phi_1^2 \Phi_H)(\Phi_1^1 \Phi_1^2 \Phi_H)\Phi_H)$, where $e$ is the second-rank totally antisymmetric tensor acting on the $SU(2)_H$ space, can be written down. But this term can be expressed as $(H^\dagger H)(\Phi_1^1 \Phi_1^2 \Phi_H)$, and therefore is not linearly independent.
(i) $U(1)_X$ is introduced to simplify the Higgs potential $V_T$ in Eq. (1). For example, a term $\Phi_I^2 \Delta_H \Phi$ obeying the $SU(2)_H$ symmetry would be allowed in the absence of $U(1)_X$. Note that as far as the scalar potential is concerned, treating $U(1)_X$ as a global symmetry is sufficient to kill this and other unwanted terms. However having a global symmetry lying around in the model defeats our original purpose of gauging the discrete global $Z_2$ symmetry. Therefore we prefer to treat $U(1)_X$ as a local symmetry.

(ii) Note that the $\mu_H^2$ and $\mu_\Phi^2$ terms in $V(H)$ and $V(\Phi_H)$ have the “right” signs while the $\mu_\Phi^2$ in $V(\Delta_H)$ has the “wrong” sign.

(iii) The quadratic terms for $H_1$ and $H_2$ have the following coefficients

$$
\mu_H^2 = \frac{1}{2} M_{H \Delta} \cdot v_\Delta + \frac{1}{2} \lambda_{H \Delta} \cdot v^2 + \frac{1}{2} \lambda_{H \Phi} \cdot v_\Phi^2,
$$

$$
\mu_\Phi^2 = \frac{1}{2} M_{H \Delta} \cdot v_\Delta + \frac{1}{2} \lambda_{H \Delta} \cdot v^2 + \frac{1}{2} (\lambda_{H \Phi} + \lambda'_{H \Phi}) \cdot v_\Phi^2.
$$

respectively. Since the four parameters $M_{H \Delta}$, $\lambda_{H \Delta}$, $\lambda_{H \Phi}$ and $\lambda'_{H \Phi}$ can take on either positive or negative values, even with a positive $\mu_H^2$, Eqs. (8) and (9) can be negative and positive respectively so that one can achieve $\langle H_1 \rangle \neq 0$ and $\langle H_2 \rangle = 0$ to break $SU(2)_L$. Because the doublet $H_2$ does not obtain a VEV, its neutral component, if lighter than the charged Higgs, can potentially be a DM candidate whose stability is protected by the $SU(2)_H$ gauge symmetry.

(iv) Similarly, the quadratic terms for two fields $\Phi_1$ and $\Phi_2$ have the coefficients

$$
\mu_\Phi^2 = \frac{1}{2} M_{\Phi \Delta} \cdot v_\Delta + \frac{1}{2} \lambda_{\Phi \Delta} \cdot v^2 + \frac{1}{2} (\lambda_{\Phi \Phi} + \lambda'_{\Phi \Phi}) \cdot v_\Phi^2,
$$

$$
\mu_\Phi^2 = -\frac{1}{2} M_{\Phi \Delta} \cdot v_\Delta + \frac{1}{2} \lambda_{\Phi \Delta} \cdot v^2 + \frac{1}{2} \lambda_{\Phi \Phi} \cdot v_\Phi^2.
$$

respectively. As in the above cases of $H_1$ and $H_2$, even with a positive $\mu_\Phi^2$, one can achieve $\langle \Phi_1 \rangle = 0$ and $\langle \Phi_2 \rangle \neq 0$ by judicious choices of the parameters.

(v) In (4), if $-\mu_\Phi^2 < 0$, $SU(2)_H$ is spontaneously broken by the VEV $\langle \Delta_\Phi \rangle = -v_\Phi \neq 0$ with $\langle \Delta_{\mu,m} \rangle = 0$ by applying an $SU(2)_H$ rotation. In fact, this also triggers the symmetry breaking of the other gauge symmetries as discussed in the next subsection.

(vi) All terms in $V(H)$, $V(\Phi_I)$, $V(\Delta_H)$ and $V_{\text{mix}}(H, \Delta_H, \Phi)$ are Hermitian, implying all the coefficients are necessarily real. Thus the scalar potential in G2HDM is $CP$-conserving.

(vii) Classification of all the symmetry breaking patterns of G2HDM like the analysis made in [2] for 2HDM would be very interesting but nevertheless beyond the scope of this work. We would like to address this issue in the future.

### C. Spontaneous symmetry breaking

To facilitate spontaneous symmetry breaking, let us shift the fields as follows

$$
H_1 = \left( \frac{G^+}{\sqrt{2}} + i \frac{G^0}{\sqrt{2}} \right), \quad H_2 = \left( \frac{H^+}{H^0} \right),
$$

$$
\Phi_H = \left( \frac{G_H^0}{\sqrt{2}} + i \frac{G_H^0}{\sqrt{2}} \right), \quad \Delta_H = \left( \frac{-v_\mu + \delta_1}{\sqrt{2}} \Delta_{\mu}, \frac{v_\nu - \delta_1}{2} \right).
$$

Here $v$, $v_\Phi$ and $v_\Delta$ are VEVs to be determined by minimization of the potential. The set $\Psi_G = \{G^+ , G^0 , G_H^0 , G_H^0 \}$ are Goldstone bosons, to be absorbed by the longitudinal components of $W^+, W^3, W^\nu, W^\nu_\nu$ respectively.

Substituting the VEVs in the potential $V_T$ in Eq. (1) leads to

$$
V_T(v, v_\Delta, v_\Phi) = \frac{1}{4} \left[ \lambda_{H \Phi} v^4 + \lambda_\Phi v_\Phi^4 + \lambda_\Delta v_\Delta^4 \right.
$$

$$
+ 2(\mu_H^2 v^2 + \mu_\Phi^2 v_\Phi^2 - \mu_\Delta^2 v_\Delta^2) - (M_{H \Delta} v^2 + M_{\Phi \Phi} v_\Phi^2) v_\Delta + \lambda_{H \Phi} v_\Delta v_\Phi^2
$$

$$
+ \lambda_{H \Delta} v^2 v_\Delta + \lambda_{H \Phi} v_\Phi v_\Phi^2 \bigg].
$$

Note that the two new couplings $\lambda_{H \Phi}$ and $\lambda'_{H \Phi}$ do not appear in Eq. (13). Thus minimization of the potential in Eq. (13) yield the same set of VEV equations as in [13]. For convenience, we here list them again

$$
(2\lambda_{H \Phi} v_\Delta^2 v_\Phi^2 - 2\mu_\Phi^2 v_\Phi^2 - \mu_\Delta^2 v_\Delta^2) = 0, \quad \lambda_{H \Delta} v_\Delta v_\Phi^2 = 0,
$$

$$
(2\lambda_{H \Phi} v_\Phi v_\Phi^2 + 2\mu_\Phi^2 v_\Phi^2 - \mu_\Delta^2 v_\Delta^2) = 0, \quad \lambda_{H \Delta} v^2 v_\Delta + \lambda_{H \Phi} v_\Phi^2 v_\Phi = 0.
$$

One can solve for nontrivial $v^2$ and $v_\Phi^2$ in terms of $v_\Delta$ and other parameters using Eqs. (14) and (15). Substituting these solutions of $v^2$ and $v_\Phi^2$ into Eq. (16) gives rise to a cubic equation of $v_\Delta$ which can be solved either analytically or numerically. Once $v_\Delta$ is known, one can substitute its value back to Eqs. (14) and (15) to determine $v$ and $v_\Phi$, respectively. In this way, one can explicitly see the effects of the triplet’s VEV $v_\Delta$ on the breaking of the SM $SU(2)_L \times U(1)_Y$ and the $U(1)_X$, after it first triggers $SU(2)_H$ symmetry breaking.
In Sec. IV, we will study numerically if this trigger mechanism can indeed happen for \( \mu_2^2 > 0 \) and \( \mu_3^2 > 0 \).

As pointed out before, the scalar potential of G2HDM is CP-conserving, since all the coefficients in the scalar potential are real. Since the triplet VEV \( v_\Delta \) satisfies a cubic equation, it may have one real and two complex solutions. The complex solutions are nevertheless unphysical and we will discard such solutions in our numerical scans described in later sections. In the cases where there are three real solutions, we will pick the one that has the lowest energy as long as it is consistent with the SM Higgs VEV \( v = 246 \text{ GeV} \).

### D. Scalar mass spectrum

The scalar boson mass spectrum can be obtained from taking the second derivatives of the potential with respect to the various fields and evaluating the results at the minimum of the potential. The mass matrix thus obtained contains three diagonal blocks. The first block is \( 3 \times 3 \). In the basis of \( S = \{ h, \phi_2, \delta_3 \} \) it is given by

\[
\mathcal{M}_0^2 = \begin{pmatrix}
2\lambda_H v^2 & \lambda_{HH} vv \phi & \frac{3}{2} \left( M_{H\Delta} - 2\lambda_{H\Delta} v_\Delta \right) \\
\lambda_{HH} vv \phi & 2\lambda_{H\Phi} v_\Phi^2 & \frac{3}{2} \left( M_{\Phi\Delta} - 2\lambda_{\Phi\Delta} v_\Delta \right) \\
\frac{3}{2} \left( M_{H\Delta} - 2\lambda_{H\Delta} v_\Delta \right) & \frac{3}{2} \left( M_{\Phi\Delta} - 2\lambda_{\Phi\Delta} v_\Delta \right) & \frac{1}{4\lambda_{v_\Delta}} \left( 8\lambda_{v_\Delta} v_\Delta^3 + M_{H\Delta} v_\Delta^2 + M_{\Phi\Delta} v_\Phi^2 \right)
\end{pmatrix}.
\]

This matrix can be diagonalized by a similarity transformation with an orthogonal matrix \( O \), defined as \( \{ f \}_i \equiv O_{ij} \{ m \}_j \) with \( \{ f \}_i \) and \( \{ m \}_j \) referring to the flavor and mass eigenstates respectively,

\[
O^T \cdot \mathcal{M}_0^2 \cdot O = \text{Diag}(m_{h_1}^2, m_{h_2}^2, m_{h_3}^2),
\]

where the three eigenvalues are in ascending order: \( m_{h_1} \leq m_{h_2} \leq m_{h_3} \). The lightest eigenstate \( h_1 \) will be identified as the 125 GeV Higgs observed at the LHC while \( h_2 \) and \( h_3 \) are the heavier Higgs bosons. The physical Higgs \( h_1 \) is a linear combination of the three components of \( S \): \( h_1 = O_{ji} S_j \). Thus the 125 GeV scalar boson could be a mixture of the neutral components of \( H_1 \) and the \( SU(2)_H \) doublet \( \Phi_\mu \), as well as the real component \( \delta_3 \) of the \( SU(2)_H \) triplet \( \Delta_H \).

The SM Higgs \( h_1 \) tree-level couplings to \( f \bar{f}, W^+ W^-, ZZ \) and \( H^+ H^- \) pairs will all be decreased by an overall factor of \( O_{11} \), implying a reduction by \( |O_{11}|^2 \) on the \( h_1 \) decay branching ratios into these channels. On the other hand, as we shall see later, \( h_1 \to \gamma \gamma \) (and also \( h_1 \to Z \gamma \)) involves extra contributions from the \( \delta_3 \) and \( \phi_2 \) components, which could lead to either enhancement or suppression with respect to the SM prediction.

The second block is also \( 3 \times 3 \). In the basis of \( G = \{ G^{p}_H, H^{0_\pm}_2, \Delta_p \} \), it is given by

\[
\mathcal{M}^2 = \begin{pmatrix}
M_{\Phi\Delta} v_\Delta + \frac{1}{2} \lambda_{H\Phi} v_\phi^2 & \frac{1}{2} \lambda_{H\Phi} v_\phi v_\Phi & -\frac{1}{2} \lambda_{H\Phi} v_\phi v_\Phi \\
\frac{1}{2} \lambda_{H\Phi} v_\phi v_\Phi & M_{H\Delta} v_\Delta + \frac{1}{2} \lambda_{H\Phi} v_\phi^2 & \frac{1}{2} \lambda_{H\Phi} v_\phi v_\Phi \\
-\frac{1}{2} \lambda_{H\Phi} v_\phi v_\Phi & \frac{1}{2} \lambda_{H\Phi} v_\phi v_\Phi & \frac{1}{4\lambda_{v_\Delta}} \left( 8\lambda_{v_\Delta} v_\Delta^3 + M_{H\Delta} v_\Delta^2 + M_{\Phi\Delta} v_\Phi^2 \right)
\end{pmatrix}.
\]

It is straightforward to show that Eq. (19) has a massless eigenstate corresponding to the physical Goldstone boson \( G^p \), which is a mixture of \( G^{p}_H, H^{0_\pm}_2 \) and \( \Delta_p \). The other two eigenvalues are the masses of two physical fields \( D \) and \( \tilde{\Delta} \):

\[
M_{D, \tilde{\Delta}}^2 = -B \pm \sqrt{B^2 - 4AC}.
\]

with

\[
A = 8v_\Delta,
B = -2(M_{H\Delta}(v^2 + 4v_\Delta^2) + M_{\Phi\Delta}(4v_\Delta^2 + v_\Phi^2) + 2\lambda_{H\Phi} v_\Phi (v^2 + v_\Delta^2)),
C = (v^2 + v_\Phi^2 + 4v_\Delta^2)(M_{H\Delta}(\lambda_{H\Phi} v_\Phi^2 + 2M_{\Phi\Delta} v_\Delta) + \lambda_{H\Phi} M_{\Phi\Delta} v_\Phi^2).
\]

The field \( D \) can be a DM candidate in G2HDM. Note that in the parameter space where the quantity inside the square root of Eq. (20) is very small, \( \tilde{\Delta} \) would be nearly degenerate with \( D \). Under this circumstance, we need to include coannihilation processes for relic density calculation. We note that, besides the scalar \( D \), it is possible in G2HDM to have fermionic \( \nu_R, \nu'_R, \nu'_L \) or vector \( W^{(p,m)} \) to be a DM candidate as well, depending on which one is

---

\(^6\)The two physical Goldstone fields are \( \tilde{G}^{p,m} \), \( v_\Phi G^p_H - vH^{0_\pm}_2 + 2v_\Delta \Delta_p \), and \( (v_\phi, -v, 2v_\Delta)^T \).

---

905006-5
the lightest. In this work, we will assume $D$ is the DM candidate. In our numerical scan, detailed in later sections, we will check to make sure $D$ must be lighter than $W^{(p,m)}, H^\pm$ and all heavy fermions.

The final block is $4 \times 4$ and diagonal with
\begin{equation}
    m^2_{H^\pm} = M_{H} + v^2 - \frac{1}{2} \lambda'_{H} v^2 \frac{1}{2} \lambda'_{H\Phi} v_{\Phi}^2, \tag{22}
\end{equation}
for the physical charged Higgs $H^\pm$, and
\begin{equation}
    m^2_{G^\pm} = m^2_{G_0} = m^2_{G_{H}} = 0, \tag{23}
\end{equation}
for the four Goldstone boson fields $G^\pm, G_0, G_{H}^0$. Note that we have used the minimization conditions Eqs. (14)–(16) to simplify various matrix elements of the above mass matrices. If the charged Higgs mass is close to the DM mass, we should include the corresponding coannihilation contributions as well.

The six Goldstone particles $G^\pm, G_0, G_{H}^0$ and $G^{p,m}$ will be absorbed by the longitudinal components of the massive gauge bosons $W^\pm, Z, Z'$ and $W^{(p,m)}$. It implies that there are two unbroken generators and thus two massless gauge particles left over after spontaneous symmetry breaking. One is naturally identified as the photon while the other one could be interpreted as a dark photon $\gamma_D$ or another neutral gauge boson $Z'$. To give a mass to the $\gamma_D$ or $Z'$, one can either use the Stueckelberg mechanism [23–26] or introduce yet another Higgs field $\Phi_X$ solely charged under $U(1)_X$ to break one of the remaining two unbroken generators. Depending on the magnitude of the Stueckelberg mass $M_X$ or the VEV $\langle \Phi_X \rangle$, one can identify the extra neutral gauge boson as either $\gamma_D$ or $Z'$. Only one unbroken generator for the massless photon should remain at the end of this game. The physical neutral gauge bosons $\gamma, Z, Z'$ and $\gamma_D/Z'$ are in principle mixtures of the gauge field components $W^3, B, W^0$ and $X$ [13].

After symmetry breaking, by scrutinizing the whole Lagrangian, one can discover that an effective $Z_2$ parity can be assigned consistently to the physical particle spectrum of the model: All the SM particles (with $h_1$ identified as the 125 GeV Higgs observed at the LHC), $Z', \gamma_D/Z'$, $h_2$ and $h_3$ are even, while $D, \Delta, H^\pm, W^{(p,m)}$ as well as all heavy fermions $f^H$ are odd under this accidental discrete symmetry. As mentioned above, we will assume $D$ is the lightest odd particle and can serve as a DM candidate in this work.

III. THEORETICAL CONSTRAINTS

In this section, we will discuss the theoretical constraints arising from tree-level vacuum stability (VS) and perturbative unitarity (PU) on the scalar sector in G2HDM.

A. Vacuum stability

For the stability of the vacuum we have to examine the scalar potential at large-field values and make sure it is bounded from below. Therefore it is sufficient to consider all the quartic terms in the scalar potential which are
\begin{equation}
    V_4 = +\lambda_H (H^\dagger H)^2 + \lambda'_{H} (H^\dagger H)^2 (H^\dagger H) + \lambda_{H\Phi} (H^\dagger H)^2 + \lambda_{\Delta} (\Delta^2 H^H)^2 + \lambda_{H\Delta} (H^H)^2 (\Delta^2 H^H) + \lambda_{\Delta\Delta} (\Delta^2 H^H)^2 (\Delta^2 H^H). \tag{24}
\end{equation}
Following the methods in [27,28], we introduce the following basis $(x, y, z)$ and two ratios $\xi$ and $\eta$, defined as
\begin{equation}
    x \equiv H^H, \tag{25}
\end{equation}
\begin{equation}
    y \equiv \Phi_H^\dagger \Phi_H, \tag{26}
\end{equation}
\begin{equation}
    z \equiv \text{Tr}(\Delta^2 H^H), \tag{27}
\end{equation}
and
\begin{equation}
    \xi = \frac{(H^H \Phi_H^\dagger \Phi^H H^H)}{(H^H)^2}, \tag{28}
\end{equation}
\begin{equation}
    \eta = \frac{(-H^H_1 H^H_1 H^H_2 + H^H_1 H^H_2 H^H_2)}{(H^H)^2}. \tag{29}
\end{equation}
One can show that the ratios satisfy $0 \leq \xi \leq 1$ and $-1/4 \leq \eta \leq 0$. While $\eta$ is always above $-1/4$, the actual lower bound and its effects will be discussed in more detail below. To deduce the conditions for the potential to be bounded from below, we rewrite the quartic terms $V_4$ in terms of $x, y$ and $z$ with the ratio parameters $\xi$ and $\eta$. That is
\begin{equation}
    V_4 = (x \ y \ z) \cdot Q(\xi, \eta) \cdot \begin{pmatrix} x \\ y \\ z \end{pmatrix}, \tag{30}
\end{equation}
with
\begin{equation}
    Q(\xi, \eta) = \begin{pmatrix} \tilde{\lambda}_H(\eta) & \frac{1}{2} \tilde{\lambda}_{H\Phi}(\xi) & \frac{1}{2} \lambda_{\Delta} \\ \frac{1}{2} \lambda_{H\Phi}(\xi) & \lambda_{\Phi} & \frac{1}{2} \lambda_{\Delta} \\ \frac{1}{2} \lambda_{\Delta} & \frac{1}{2} \lambda_{\Delta} & \tilde{\lambda}_H(\eta) \end{pmatrix}, \tag{31}
\end{equation}
and
\begin{equation}
    \tilde{\lambda}_H(\eta) \equiv \lambda_H + \eta \lambda'_{H\Phi}, \quad \tilde{\lambda}_{H\Phi}(\xi) \equiv \lambda_{H\Phi} + \xi \lambda'_{H\Phi}.
\end{equation}
According to [29,30], using the Sylvester’s criterion or requiring semipositive definite eigenvalues of the quadratic form $Q(\xi, \eta)$, albeit mathematically rigorous,
overly constrain the parameter space in this case. Instead, the notion of copositivity (conditionally positive) criteria was proposed for vacuum stability conditions. This is because the Sylvester’s criterion or positive semidefinite requirement applies to the case that the basis \((x, y, z)\) can be either positive or negative, whereas copositivity is applicable to the situation of positive (or non-negative) \((x, y, z)\) only. As our \(x, y\) and \(z\) are the square of the scalar fields and thus non-negative, we will use the copositivity criteria accordingly.\(^7\) The copositivity criteria for the \(3 \times 3\) symmetric matrix \(Q(\xi, \eta)\) are \([29,30]\)

\[
\tilde{\lambda}_H(\eta) \geq 0, \quad \lambda_\Phi \geq 0, \quad \lambda_\Delta \geq 0, \quad (32)
\]

\[\Lambda_{H\Phi}(\xi, \eta) = \tilde{\lambda}_H(\xi) + 2\sqrt{\tilde{\lambda}_H(\eta)\lambda_\Phi} \geq 0,\]

\[\Lambda_{H\Delta}(\eta) = \tilde{\lambda}_H + 2\sqrt{\tilde{\lambda}_H(\eta)\lambda_\Delta} \geq 0,\]

\[\Lambda_{\Phi\Delta} = \lambda_\Phi + 2\sqrt{\lambda_\Phi\lambda_\Delta} \geq 0, \quad (33)\]

\[\Lambda_{H\Phi\Delta}(\xi, \eta) = \sqrt{\tilde{\lambda}_H(\eta)\lambda_\Phi\lambda_\Delta} + \frac{1}{2}(\tilde{\lambda}_H(\xi)\sqrt{\tilde{\lambda}_H(\eta)} - \lambda_\Delta)
\]

\[\Lambda_{H\Phi\Delta}(\xi, \eta) = \sqrt{\tilde{\lambda}_H(\eta)\lambda_\Phi\lambda_\Delta} + \frac{1}{2}(\tilde{\lambda}_H(\xi)\sqrt{\tilde{\lambda}_H(\eta)} - \lambda_\Delta)
\]

\[+ \frac{1}{2}\sqrt{\Lambda_{H\Phi}(\xi, \eta)\Lambda_{H\Delta}(\eta)\Lambda_{\Phi\Delta}} \geq 0, \quad (34)\]

with \(0 \leq \xi \leq 1\) and \(-1/4 \leq \eta \leq 0\) as stated before. As shown in \([29]\), these copositivity criteria are necessary and sufficient conditions for the quartic potential to be bounded from below.

It is easy to see that for a given set of \(\tilde{\lambda}\) parameters, the conditions above are monotonic functions of the ratios \(\xi\) and \(\eta\). If this last two ratios were perfectly independent, it would be enough to check Eqs. (32)–(34) only at the boundaries of said ratios. However, in our case there is a correlation between the lower bound of \(\eta\) and the value of \(\xi\) given by \(\eta_{\min} = \xi(\xi - 1)\). Since this constraint limits the value of \(\eta\) to be well inside the rectangle defined by the original boundaries mentioned above, checking the corners of the rectangle would actually yield stronger constraints on the scalar potential parameters. Instead, we should check the boundary defined by \(\eta_{\min} = \xi(\xi - 1)\) for \(\Lambda_{H\Phi}(\xi, \eta_{\min})\) and \(\Lambda_{H\Phi\Delta}(\xi, \eta_{\min})\).

We apply the method outlined in \([32]\) to \(\Lambda_{H\Phi}(\xi, \eta_{\min})\) and \(\Lambda_{H\Phi\Delta}(\xi, \eta_{\min})\) to find the actual conditions to apply. In particular, we need to check the minimum values of \(\Lambda_{H\Phi}(\xi, \eta_{\min})\) and \(\Lambda_{H\Phi\Delta}(\xi, \eta_{\min})\), when necessary, in the boundary mentioned above. Consider the first derivative of \(\Lambda_{H\Phi}(\xi, \eta_{\min})\) with respect to \(\xi\) at the boundary defined by \(\eta_{\min} = \xi(\xi - 1)\).

\[
\frac{d\Lambda_{H\Phi}(\xi, \eta_{\min})}{d\xi} = \lambda'_{H\Phi} \frac{2\xi - 1}{\lambda'_{H\Phi}(\xi^2 - \xi) + \lambda_H}
\]

By solving \(d\Lambda_{H\Phi}(\xi, \eta_{\min})/d\xi = 0\), we find the minimum \(\xi_0\)

\[
\xi_0 = \frac{1}{2} - \frac{\lambda'_{H\Phi}}{2} \sqrt{-\lambda'_{H\Phi} + 4\lambda_H}
\]

For this \(\xi_0\) to be inside the \((0,1)\) range, the absolute value of the second term must be smaller than \(1/2\). This results in the condition \((\lambda'_{H\Phi})^2 \lambda_H < (\lambda'_{H\Phi})^2 \lambda_H\). If \(\xi_0\) is not in the \((0,1)\) range we can skip the following checks.

If \(\xi_0\) is inside the \((0,1)\) range we can check that it is actually a minimum by finding the sign of the second derivative, given by

\[
\frac{d^2\Lambda_{H\Phi}(\xi, \eta_{\min})}{d\xi^2} = \lambda'_{H\Phi} \frac{\lambda_{\Phi}(\lambda'_{H\Phi}(\xi - 1) + \lambda_H)((\lambda'_{H\Phi})^2(2\xi - 1)^2 + 2)}{(\lambda'_{H\Phi}(\xi - 1) + \lambda_H)^2}
\]

By substituting \(\xi = \xi_0\) we find that the sign of the second derivative is given by the sign of \(\lambda'_{H\Phi}\). If \(\lambda'_{H\Phi}\) is negative, then \(\Lambda_{H\Phi}(\xi, \xi^2 - \xi)\) is concave and it is enough to check the boundary points \((\xi, \eta_{\min}) = (0,0)\) and \((1,0)\). But if \(\lambda'_{H\Phi}\) is positive then we have a minimum and we have to check if \(\Lambda_{H\Phi}(\xi_0, \xi^2 - \xi_0) \geq 0\).

In summary, to make sure that \(\Lambda_{H\Phi}(\xi, \eta) \geq 0\) we have to check:

\[
\Lambda_{H\Phi}(\xi = 0, \eta = 0) \geq 0 \quad \text{and} \quad \Lambda_{H\Phi}(\xi = 1, \eta = 0) \geq 0,
\]

\[
\text{for other rigorous method to deduce the necessary and sufficient conditions for various scalar potentials in BSM to be bounded from below, see e.g., [31].}
\]

\(\text{for other rigorous method to deduce the necessary and sufficient conditions for various scalar potentials in BSM to be bounded from below, see e.g., [31].}\)
and only in the cases that both conditions \( \lambda_H^\prime > 0 \) and \( (\lambda_H^\prime)^2 \lambda_H < (\lambda_H^\prime)^2 \lambda_\Phi \) apply we also need to check:

\[
\Lambda_H(\xi_0, \xi_0^\prime - \xi_0) = \lambda_H + \frac{\lambda_H^\prime}{2} + \frac{1}{4} \sqrt{4 \lambda_H^\prime (\lambda_H^\prime)^2 - \left( \frac{4 \lambda_H^\prime \lambda_\Phi}{\lambda_H^\prime} - 1 \right)} \geq 0.
\]  

(39)

This same procedure can be applied to \( \Lambda_H(\xi_0, \eta_{\text{min}}) \) defined by Eq. (34) but the resulting expressions are far more complicated and add little to nothing to the discussion. However we follow the same procedure and, in addition to the boundary points at \((\xi, \eta) = (0, 0)\) and \((1, 0)\), we also check the corresponding minimum when needed.

For the rest of the conditions, if such a minimum exists, it corresponds to the point \((\xi, \eta) = (1/2, -1/4)\), which we also check together with the \((0, 0)\) and \((1, 0)\) boundary points.

### B. Perturbative unitarity

To infer the tree-level perturbative unitarity constraints on the scalar potential parameters, similar to the discussion of vacuum stability above it is sufficient to focus on the quartic couplings. The reason is that at high energies the \( 2 \to 2 \) scatterings induced by either the scalar cubic couplings or gauge interactions are suppressed by the propagator (which is inversely proportional to momentum transfer squared) compared to those induced by the quartic couplings which do not have such a momentum dependence. We will follow the same procedures adopted in \cite{17,19,33} that deduce the perturbative unitarity constraints for the SM, 2HDM and IHDM.

In terms of the physical and Goldstone bosons defined in Eq. (12), the quartic terms \( V_4 \) can be written as

\[
V_4 = + \frac{1}{4} \lambda_H (h^2 + (G^0)^2 + 2G^+ G^- + 2H^0 H^0 + 2H^+ H^-)^2 + \frac{1}{4} \lambda_H (h^2 + (G^0)^2 + 2G^+ G^- + 2H^0 H^0 + 2H^+ H^-)^2 \\
+ \frac{1}{4} \lambda_{\phi^2} (\delta_\phi^2 + 2\Delta_\phi \Delta_m)^2 + \frac{1}{4} \lambda_H (h^2 + (G^0)^2 + 2G^+ G^- + 2H^0 H^0 + 2H^+ H^-)^2 (\delta_\phi^2 + (G_\phi^0)^2) \\
+ \lambda_H \left\{ \left( \frac{1}{2} (h^2 + (G^0)^2 + 2G^+ G^-) G_H^0 G_H^0 + (H^+ H^- + H^0 H^0) G_H^0 \right) \right. \\
+ \left. \left( G^- H^+ + \frac{1}{2} (h - i G_0) H_2^0 \right) G_H^0 \right\} \frac{1}{\sqrt{2}} (\phi_2 - i G_0^0) + \left( G^+ H^- + \frac{1}{2} (h + i G_0) H_2^0 \right) G_H^0 \frac{1}{\sqrt{2}} (\phi_2 + i G_0^0) \\
+ \frac{1}{4} \lambda_{\phi^2} (h^2 + (G^0)^2 + 2G^+ G^- + 2H^0 H^0 + 2H^+ H^-)^2 (\delta_\phi^2 + 2\Delta_\phi \Delta_m) \\
+ \frac{1}{4} \lambda_{\phi^2} (\delta_\phi^2 + (G_\phi^0)^2) + 2G_H^0 G_H^0 (\delta_\phi^2 + 2\Delta_\phi \Delta_m)).
\]  

(40)

We now analyze all the \( 2 \to 2 \) scalar scatterings induced by the above quartic potential.

(1) The scattering amplitudes with the initial and final states containing one of the following states

\[
\left\{ \frac{h h}{\sqrt{2}}, \frac{G^0 G^0}{\sqrt{2}}, G^+ G^-, H^0 H^0, H^+ H^-, \frac{\phi_2 \phi_2}{\sqrt{2}}, \frac{G_H^0 G_H^0}{\sqrt{2}}, \frac{G_H^0 G_H^0}{\sqrt{2}}, \frac{\delta_\phi \delta_\phi}{\sqrt{2}}, \Delta_\phi \Delta_m \right\}
\]

(41)

can be straightforwardly computed based on Eq. (40). The corresponding amplitude matrix \( M_i \) in the basis of Eq. (41) is

\[\text{We have included in the amplitude a symmetry factor of } 1/\sqrt{2} \text{ for identical particles in the initial and final states.}\]
\[
M_1 = \begin{pmatrix} 
3\lambda_H & \lambda_H & \frac{3}{\sqrt{2}} \lambda_H & \frac{3}{\sqrt{2}} \lambda_H & \frac{3}{2} \lambda_H & \frac{3}{2} \lambda_H & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} \\
\lambda_H & 3\lambda_H & \frac{3}{\sqrt{2}} \lambda_H & \frac{3}{\sqrt{2}} \lambda_H & \frac{3}{2} \lambda_H & \frac{3}{2} \lambda_H & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} \\
\frac{3}{2} \lambda_H & \frac{3}{2} \lambda_H & 4\lambda_H & 2\lambda_H & \frac{1}{\sqrt{2}} \lambda_H & \frac{1}{\sqrt{2}} \lambda_H & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} \\
\frac{3}{2} \lambda_H & \frac{3}{2} \lambda_H & 2\lambda_H & 4\lambda_H & \frac{1}{\sqrt{2}} \lambda_H & \frac{1}{\sqrt{2}} \lambda_H & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} \\
\frac{3}{2} \lambda_H & \frac{3}{2} \lambda_H & 2\lambda_H & 4\lambda_H & \frac{1}{\sqrt{2}} \lambda_H & \frac{1}{\sqrt{2}} \lambda_H & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} \\
\frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \lambda_H & \lambda_H & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} \\
\frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} & \lambda_H & \lambda_H & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} \\
\lambda_H & \lambda_H & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} & \lambda_H & \lambda_H & \lambda_H & \lambda_H & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} \\
\frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} & \lambda_H & \lambda_H \\
\frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Phi} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} & \frac{1}{2} \lambda_{H\Delta} & \lambda_H \\
\end{pmatrix},
\]

where the \((i, j)\) element corresponds to the amplitude between the states of the \(i\)th and \(j\)th element of the basis; for instance, the \((1,1)\) element represents the amplitude of the process \(hh \rightarrow hh\). Here \(\tilde{\lambda}_H = \lambda_H - \lambda_H'/2\), \(\tilde{\lambda}_{H\Phi} = \lambda_{H\Phi} + \lambda_{H\Phi}'/2\).

There are 10 eigenvalues in total and seven of them are given by:

\[
\lambda_1 = 2\lambda_H, \quad \lambda_2 = 2\lambda_{H\Phi}, \quad \lambda_3 = 2\lambda_{H\Delta}, \quad \lambda_4, 5 = 2\lambda_H \pm \lambda_H',
\]

\[
\lambda_{6, 7} = \tilde{\lambda}_H + \lambda_{\Phi} \pm \sqrt{2\lambda_H^2 + (\tilde{\lambda}_H - \lambda_{\Phi})^2},
\]

where \(\tilde{\lambda}_H = \lambda_H + \lambda_H'/2\). The rest of the eigenvalues are the three roots of the equation \(\lambda^3 + a\lambda^2 + b\lambda + c = 0\) with

\[
a = -5\lambda_H - 6\lambda_{H\Phi} - 10\lambda_{H\Delta} + \lambda_H',
\]

\[
b = -6\lambda_{H\Delta}^2 - 3\lambda_{H\Phi}^2 + 5\lambda_{H\Phi}(10\lambda_{H\Phi} - \lambda_H - 6\lambda_H\Phi),
\]

\[
c = 36\lambda_{H\Phi}\lambda_{H\Delta}^2 - 24\lambda_{H\Delta}\lambda_{H\Phi}(\lambda_{H\Phi} + \lambda_{H\Phi}'/2),
\]

\[
+ 40\lambda_{H\Delta}(\lambda_{H\Phi} + \lambda_{H\Phi}'/2)^2 + (3\lambda_{H\Phi}^2 - 30\lambda_{H\Phi}\lambda_{H\Delta})(10\lambda_{H\Phi} - \lambda_{H\Phi}').
\]

which can be solved either numerically or analytically. Since at very high center-of-mass energies all masses can be ignored, one can take \(\sqrt{3} \rightarrow \infty\). The \(2 \leftrightarrow 2\) scatterings among the scalars are then governed by the quartic couplings. The amplitudes are all constants without energy dependence and we can focus on the \(s\)-wave [17]. Unitarity constraints then require all the 10 real eigenvalues \(\lambda_i\) of the Hermitian \(M_1\) to satisfy [17–19,33]

\[
|\lambda_i(M_1)| \leq 8\pi, \quad \forall \ i = 1, \ldots, 10.
\]

There also exist processes involving different particles in the initial and final states that can be divided into the following groups:

(II) For the basis \(\{hH^{0+}, G^0H^{0+}, G^+H^-\}\) as initial and final states, we have the following scattering matrix

\[
M_2 = \begin{pmatrix} 
2\lambda_H & 0 & \frac{\sqrt{3}}{2} \lambda_H' \\
0 & 2\lambda_H & \frac{\sqrt{6}}{2} \lambda_H' \\
\frac{\sqrt{6}}{2} \lambda_H' & -\frac{\sqrt{6}}{2} \lambda_H' & 2\lambda_H \\
\end{pmatrix},
\]

with eigenvalues \(2\lambda_H\) and \(2\lambda_H \pm \lambda_H'\).

(III) For the basis \(\{hG^+, H^{0+}_2, H^{0+}_2, G^0H^+\}\), we find the scattering matrix is the same as that in Eq. (45).

(IV)
\[
M(hG^0 \leftrightarrow hG^0) = M(G^+H^+ \leftrightarrow G^+H^+) = 2\lambda_H.
\]

(V)
\[
M(hH^+ \leftrightarrow hH^+) = M(G^0H^+ \leftrightarrow G^0H^+)
\]

\[
= M(H^{0+}_2G^+ \leftrightarrow H^{0+}_2G^+) = 2\lambda_H.
\]

(VI)
\[
M(G^+H^0 \leftrightarrow hH^+, G^0H^+) = \frac{1}{\sqrt{2}} (1, -i)\lambda_H'.
\]

(VII)
\[
M(\phi_2G^{0+}_1 \leftrightarrow \phi_2G^{0+}_1) = M(\phi_2G^{0+}_1 \leftrightarrow \phi_2G^{0+}_1)
\]

\[
= M(G^{0+}_1H^{0+}_2 \leftrightarrow G^{0+}_1H^{0+}_2)
\]

\[
= 2\lambda_{\Phi}.
\]

(VIII)
\[
M(\delta_3 \Delta_p \leftrightarrow \delta_3 \Delta_p) = 2\lambda_{\Delta}.
\]
The scattering amplitudes of the following processes
\[ h\phi_2 \leftrightarrow h\phi_2, \quad hG_H^p \leftrightarrow hG_H^p, \]
\[ G_H^0 \phi_2 \leftrightarrow G_H^0 \phi_2, \quad G_H^0 G_H^0 \leftrightarrow G_H^0 G_H^0, \]
\[ G_H^+ \phi_2 \leftrightarrow G_H^+ \phi_2, \quad G_H^+ G_H^0 \leftrightarrow G_H^+ G_H^0, \]
are all equal to \( \tilde{\lambda}_{H\Phi} \).

The scattering amplitudes of the following processes
\[ hG_H^p \leftrightarrow hG_H^p, \quad G_H^0 G_H^0 \leftrightarrow G_H^0 G_H^0, \]
\[ G_H^+ G_H^0 \leftrightarrow G_H^+ G_H^0, \]
are all equal to \( \tilde{\lambda}_{H\Phi} \).

The scattering amplitudes of the following processes
\[ H_2^0 G_H^0 \leftrightarrow H_2^0 G_H^0, \quad H_2^0 G_H^0 \leftrightarrow H_2^0 G_H^0, \]
\[ H_2^+ \phi_2 \leftrightarrow H_2^+ \phi_2, \quad H_2^+ G_H^0 \leftrightarrow H_2^+ G_H^0, \]
are all equal to \( \tilde{\lambda}_{H\Phi} \).

The scattering amplitudes of the following processes
\[ M(G_H^p G^- \leftrightarrow H^- \phi_2) = \frac{1}{\sqrt{2}} \tilde{\lambda}_{H\Phi}, \]
\[ M(G_H^p H_2^0 \leftrightarrow h\phi_2) = -M(G_H^p H_2^0 \leftrightarrow G_H^0 G_H^0) = \frac{1}{2} \tilde{\lambda}_{H\Phi}, \]
are all equal to \( \lambda_{H\Delta} \).

To summarize: For the above 13 groups of scattering processes, perturbative unitarity requires the following constraints
\[ |\lambda_i(M_1)| \leq 8\pi, \quad \forall \ i = (1, \ldots, 10), \]
\[ |\lambda_H| \leq 4\pi, |\lambda_H'| \leq 8\sqrt{2}\pi, |2\lambda_H \pm \lambda_H'| \leq 8\pi, |\lambda_H| \leq 4\pi, |\lambda_{H\Delta}| \leq 4\pi, \]
\[ |\lambda_{H\Phi}| \leq 8\pi, |\tilde{\lambda}_{H\Phi}| = |\lambda_{H\Phi} + \lambda_{H\Phi}'| \leq 8\pi, |\lambda_{H\Phi}| \leq 8\sqrt{2}\pi, \]
\[ |\lambda_{H\Delta}| \leq 8\pi, |\lambda_{H\Delta}| \leq 8\pi. \]

In fact, the allowed regions projected on to the \( \lambda_H - \lambda_{H\Phi} \) and \( \lambda_{H\Phi} - \lambda_{H\Delta} \) plane behave quite similarly to those of \( \lambda_{H\Phi} - \lambda_{H\Phi}' \) and \( \lambda_{H\Phi}' - \lambda_{H\Delta} \). The green and blue regions are the allowed regions by VS and PU respectively, while only the red regions are allowed when both VS and PU are considered. Clearly, the constraints from PU [Eq. (60)] alone will impose upper limits on all diagonal couplings \( \lambda_i \), where \( i = (H, \Phi, \Delta) \), as shown by the blue regions for the cases of \( \lambda_{H\Phi} \) and \( \lambda_{H\Delta} \). On the other hand, the green regions from the constraints of VS Eqs. (32)–(34) restrict the off-diagonal \( \lambda_{H\Phi} \) and \( \lambda_{H\Delta} \) to be greater than –2 for the diagonal \( \lambda_i < 0.1 \). In contrast, for larger \( \lambda_i \), the windows for negative values of \( \lambda_{H\Phi} \) and \( \lambda_{H\Delta} \) are widened.

The small wedgelike regions bounded by the green, blue and red contours with negative \( \lambda_{H\Phi} - \lambda_{H\Delta} \) and \( 0.1 \gtrless \lambda_H \), \( \lambda_{H\Phi} \leq 4 \) are allowed by either VS or PU alone. However
as both the VS and PU constraints are imposed, this region is excluded as the two constraints are in tension. We found that this tension is mainly caused by a nontrivial combination of the copositive conditions in Eq. (33) and the unitarity constraints in Eq. (60). Loosely speaking, if the off-diagonal $\lambda_{ij}$ is negative, then larger $\lambda_i$ and $\lambda_j$ are needed as indicated in Eq. (33). However, the PU conditions set limits on the size of the diagonal couplings $|\lambda_{H\Delta}|$ which in turn implies lower limits on the off-diagonal $\lambda_{ij}$ via the VS constraint in Eq. (33). The last VS constraint of Eq. (34) actually does not yield much more information since the only couplings therein that can be negative are $\tilde{\lambda}_{H\Phi}(\xi)$, $\tilde{\lambda}_{H\Delta}$ and $\tilde{\lambda}_{\Phi\Delta}$, whose lower limits are already constrained by Eq. (33).

In the upper- and lower-right panels of Fig. 1, the allowed regions on the $(\lambda_{H\Phi}, \lambda_{H\Delta})$ and $(\lambda_{H}, \lambda_{H\Phi})$ plane are presented. As in the left panels, the green boundaries are constrained by VS. However, unlike $\lambda_{H}$ constrained to be positive, a negative value of $\lambda_{H}$ is more favored. Recall that $\tilde{\lambda}_{H}(\eta) = \lambda_{H} + \eta \lambda_{0H}$ with $-0.25 \leq \eta \leq 0$. $\tilde{\lambda}_{H}(\eta)$ would turn negative if $\lambda_{0H}$ becomes too positive. This violates one of the VS constraints, $\tilde{\lambda}_{H}(\eta) \geq 0$ in Eq. (32). Similar to the two left panels, the small wedgelike regions surrounded by blue and red contours are excluded when the both VS and PU constraints are taken into account.

In Fig. 2, we present the allowed regions for the off-diagonal terms $\lambda_{ij}$. Obviously, smaller $\lambda_{ij}$ are always allowed by all the theoretical constraints. The limits of $\lambda_{ij}$ obtained from the PU conditions are $|\lambda_{H\Phi}| \lesssim 18$, $|\lambda_{H\Delta}| \lesssim 18$, $|\lambda_{\Phi\Delta}| \lesssim 15$, and $|\lambda_{H\Delta}| \lesssim 11$. Interestingly,
\( \lambda_{H\Delta} \) is slightly more stringent than others because it has relatively large coefficients inside the scattering matrix \( M_1 \) in Eq. (42).

On the other hand, effects of the VS condition are hardly visible in the parameter space except for the \( \lambda_{H\Phi} - \lambda'_{H\Phi} \) plane. The constraints originate from the parameter \( \bar{\lambda}_{H\Phi}(\xi) \). Recall that \( \bar{\lambda}_{H\Phi}(\xi) \equiv \lambda_{H\Phi} + \lambda'_{H\Phi} \xi \) with \( 0 \leq \xi \leq 1 \). From the first inequality of Eq. (33) \( \bar{\lambda}_{H\Phi}(\xi) \geq -2\sqrt{\bar{\lambda}_{H}(\eta)\lambda_{H\Phi}} \), it implies \( \lambda_{H\Phi} \) and \( \lambda'_{H\Phi} \) cannot be too negative at the same time, leading to the blank bottom-left corner in the bottom-left panel of Fig. 2. As already explained in Fig. 1, when we combine both constraints from VS and PU, the allowed region is further shrunk due to the tension between the copositive conditions Eq. (33) and the unitarity limits Eq. (60).

IV. HIGGS PHENOMENOLOGY

In this section, we will consider the phenomenological constraints from the Higgs physics at the LHC.

A. Higgs diphoton decay

In G2HDM, as explained above the 125 GeV Higgs boson \( h_1 \) is a linear combination of \( h, \phi_2 \) and \( \delta_3 \):

\[
h_1 = O_{11} h + O_{21} \phi_2 + O_{31} \delta_3, \tag{61}
\]

where \( O_{ij} \) are the elements of the orthogonal matrix \( O \) that diagonalizes the mass matrix \( \mathcal{M}_0^2 \) displayed in Eq. (18). The mixing has an impact on both the \( ggH \) production and Higgs decay branching ratio into two photons.
Due to the narrow Higgs decay width, the Higgs production will be dominated by the resonance region and thus the cross section \(\sigma(pp \to h_1 \to \gamma\gamma)\) can be well approximated by [34]

\[
\sigma(gg \to h_1 \to \gamma\gamma) = \frac{\pi^2}{8 \sin \theta_{h_1}} f_{gg}(\sqrt{s}) \left(\frac{m_{h_1}}{\sqrt{s}}\right) \times \Gamma(h_1 \to gg) \Gamma(h_1 \to \gamma\gamma),
\]

with the center of mass energy \(\sqrt{s} = 13\) TeV and the integral of the parton (gluon in this case) distribution function product

\[
f_{gg}(\sqrt{s}) = \int_1^\infty dx \frac{1}{x} g(x, \mu^2) g\left(\frac{y}{x}, \mu^2\right),
\]

evaluated at the scale of \(\mu = m_{h_1} = 125\) GeV. The corresponding signal strength for \(ggH\) production is

\[
\mu_{ggH} = \frac{\Gamma_{SM}(h_1 \to gg) \Gamma(h_1 \to \gamma\gamma)}{\Gamma_{h_1} \Gamma_{SM}(h \to gg) \Gamma(h \to \gamma\gamma)}
\]

where the superscript SM refers to the SM Higgs boson \(h\). In G2HDM, \(\Gamma(h_1 \to gg)\) receives additional contributions from the new colored heavy fermions while \(\Gamma(h_1 \to \gamma\gamma)\) has extra contributions from both the new charged heavy fermions and the charged Higgs \(H^\pm\). As a result, one has [13,35-38]

\[
\Gamma(h_1 \to \gamma\gamma) = \frac{G_F \alpha^2 m_{h_1}^3 O_{12}^2}{128 \sqrt{2} \pi^3} A_1(\tau_{W^\pm}) + \sum_F N_C Q_F^2 A_{1/2}(\tau_F)
\]

\[+ C_h \frac{\lambda_H v^2}{m_{H^\pm}^2} \left[ A_0(\tau_{H^\pm}) + \frac{O_{21} v}{O_{11} \phi} \sum_F N_C Q_F^2 A_{1/2}(\tau_F) \right]^2,
\]

with \(N_C\) being the number of color and

\[
C_h = 1 + \frac{O_{21}(\lambda_H + \lambda_H') v \phi}{O_{11} 2(\lambda_H + \lambda_H') v \phi} - \frac{O_{31}}{O_{11}} \frac{2(\lambda_H + \lambda_H') v \phi + M_{H^\pm}}{4 \lambda_H v}
\]

where \(\lambda_H = \lambda - \lambda_H' / 2\). The symbol \(f\) refers to the SM fermions while \(F\) denotes the heavy fermions. The form factors for spins 0, \(\frac{1}{2}\) and 1 particles are given by

\[
\begin{align*}
A_0(\tau) &= -|\tau - f(\tau)| \tau^2, \\
A_{1/2}(\tau) &= 2|\tau + (\tau - 1)f(\tau)| \tau^2, \\
A_1(\tau) &= -2\tau^2 + 3\tau + 3(\tau - 1)f(\tau) |\tau|^2,
\end{align*}
\]

with the function \(f(\tau)\) defined as

\[
f(\tau) = \begin{cases} 
\arcsin^2 \sqrt{\tau} & \text{for } \tau \leq 1, \\
\frac{1}{4} \left[ \log \frac{1+\sqrt{1-\tau}}{1-\sqrt{1-\tau} - i\pi} \right]^2 & \text{for } \tau > 1.
\end{cases}
\]

The parameters \(\tau_i = m_{h_i}^2 / 4 m_{h_1}^2\) with \(i = H^\pm, f, F, W^\pm\) are related to the corresponding masses of the particles in the loops. Other symbols not defined in Eq. (65) are self-explanatory. As is well known in the SM, even if the W gauge boson or top quark becomes infinitely heavy (\(\tau_i \to 0\)), they do not decouple in the triangle loop and have still finite contributions due to \(A_{1/2}(0) = 4/3\) and \(A_1(0) = -7\). Moreover, \(h_{SM} \to \gamma\gamma\) is dominated by the \(W^\pm\) loop contribution, while the top quark contribution is subdominant and has destructive interference with that of \(W^\pm\). In G2HDM, the extra contributions from charged Higgs and new heavy charged fermions to the diphoton channel can either be constructive or destructive with the SM ones, depending on the signs of \(C_h\) and \(O_{21}/O_{11}\) respectively. However, due to an extra factor of \(1/m_{h_1}^2\) in front of \(A_0(\tau_{W^\pm})\) and the small ratio \(v/\langle \phi \rangle\) in front of \(A_{1/2}(\tau_F)\) in Eq. (65), both the contributions from the very heavy charged Higgs and extra fermions are not significant in the diphoton channel. They are effectively decoupled in the large mass limit in G2HDM.

On the other hand, the partial decay width of \(h_1\) into two gluons mediated by the SM quarks and the new colored fermions is [35-37]

\[
\Gamma(h_1 \to gg) = \frac{\alpha^2 m_{h_1}^3 O_{12}^2}{72 \pi^2 v^3} \sum_F \frac{3}{4} A_{1/2}(\tau_F)
\]

\[+ \frac{O_{21} v}{O_{11} \phi} \sum_F \frac{3}{4} A_{1/2}(\tau_F) \]

(69)

Depending on the sign of \(O_{21}/O_{11}\), the contributions from the new heavy quarks in G2HDM can increase or decrease the branching fraction. Note also the suppression factor of the small ratio \(v/\langle \phi \rangle\) for the contributions from new heavy quarks.

Finally, the SM prediction for the branching ratios of \(h \to gg\) and \(h \to \gamma\gamma\) can be easily obtained from the previous formulas by setting \(O_{11} = 1\) and \(O_{21} = O_{31} = 0\) and neglecting the contributions from the new heavy fermions and \(H^\pm\).

**B. Numerical results from Higgs physics**

In this subsection, we will discuss constraints on the scalar quartic couplings \(\lambda_{ij}\) from Higgs physics only (marked in orange) and from Higgs physics (HP) plus the aforementioned theoretical conditions (marked in magenta). We also colored in red the theoretical constraints alone as before. Here, we include the HP experimental constraints in the 2\(\sigma\) range from the ATLAS experiment [39]:

(i) Higgs mass \(m_h = 125.09 \pm 0.24\) GeV, and
FIG. 3. Allowed regions of the parameter space by the HP, (VS + PU) and (VS + PU + HP) constraints projected onto the planes of $(\lambda_H, \lambda_{HP}), (\lambda_H, \lambda_{H}\Delta), (\lambda_\Phi, \lambda_{HP}), (\lambda_H', \lambda_{H}\Delta)$ and $(\lambda_\Delta, \lambda_{H}\Delta)$. 

ARHRIB, HUANG, RAMOS, TSAI, and YUAN PHYS. REV. D 98, 095006 (2018)
FIG. 4. Allowed regions of the parameter space by the (VS + PU) and (VS + PU + HP) constraints projected onto the $\lambda_{H\Delta}, \lambda_{H\Phi}$ planes.

FIG. 4. Allowed regions of the parameter space by the (VS + PU) and (VS + PU + HP) constraints projected onto the $(\lambda_{H\Phi}, \lambda_{H\Delta}), (\lambda_{H\Phi}, \lambda_{H\Delta}), (\lambda_{H\Phi}, \lambda_{H\Delta}), (\lambda_{H\Phi}, \lambda_{H\Delta})$ and $(\lambda_{H\Phi}, \lambda_{H\Delta})$ planes.
Additional parameters needed to be considered in this value of $\mu^2_H$. These parameters have been chosen, the minimization allowed ranges for all the $\lambda$-parameters from the theoretical VS and PU conditions, one obtains $\lambda_H > 0.13$. To increase $m_h$, one would need $\lambda_H \geq 0.13$. By including the constraints from VS and PU conditions, one obtains $0.13 \leq \lambda_H \leq 4.0$ and $0 \leq \lambda_\Phi \leq 4.19$. The allowed range of $\lambda_H$ is wider than that of $\lambda_H$, which is simply because the value of $v_\phi$ is fixed but $v_\Delta$ is varied in our setup. In general the theoretical (VS + PU) constraints are much stringent than the Higgs data constraint.

Similarly, in the right column of Fig. 3, we plot the allowed regions from top to bottom for the $(\lambda_H, \lambda_\Phi)$, $(\lambda_H, \lambda_{\Delta})$ and $(\lambda_H)$ planes. Since as indicated in the left panels current LHC Higgs data is more sensitive to the parameters $\lambda_H$ and to a lesser extent $\lambda_{\Delta}$ but not others, we will not show the Higgs data constraints in all the subsequent plots. Instead we present only the theoretical (VS + PU) constraints in red and the combined (VS + PU + HP) constraints in magenta. It is clear that

$^{15}$Mixing effects that lead to decreasing the lightest eigenstate mass can also occur in the fermion case. One famous example is the Type-I seesaw mechanism, in which the contribution from the heavy right-handed neutrino to the light neutrino mass is actually negative which can be made positive via field redefinition.
combining the Higgs data constraints with the theoretical constraints can further reduce the allowed regions for these parameters—most significantly on the $(\lambda_0 H, \lambda H \Phi)$ plane. Allowed regions of other two-dimensional planes of diagonal versus off-diagonal parameters will be summarized in the next section.

Next, we present the impacts of HP constraints on some of purely off-diagonal parameter planes $(\lambda_{ij}, \lambda_{kl})$ in Fig. 4. Comparing the two parameters $\lambda_{ij}$ and $\lambda_{kl}$, their favored regions by the Higgs data behave quite differently as they are constrained in different ways. The exclusion of the region $\lambda_{ij} \gtrsim 4$ is owing to the SM Higgs mass, whereas $\lambda_{ij}$ is forced to be greater than $-1$, in light of prohibition of tachyonic modes for any of the scalars. Overall, $\lambda_{ij}$ is more constrained by the Higgs physics data than $\lambda_{ij}$ and $\lambda_{kl}$. Allowed regions on the other planes of off-diagonal versus off-diagonal parameters will be summarized in the next section.

In addition to the above bounds on $\lambda$ s, we find that the mass parameter $M_{\Phi \Delta}$ has a lower limit $\lesssim -0.56$ GeV while the mass parameter $M_{H \Delta}$ and the VEV $v_\Delta$ remain unconstrained within their ranges of scanning. The lower bound on $M_{\Phi \Delta}$ arises from the observation that the $B$ term defined in Eq. (21) must be negative in order to attain positive $M_{\Delta}$ and $M_{\Delta}$. Note that since $v_\Delta$ and $v_\Phi$ are much larger than $v$, $B$ can then be approximated as $-2(4v_\Delta m_{H^*}^2 + M_{\Phi \Delta}(4v_\Delta^2 + v_\Phi^2))$. This means that $M_{\Phi \Delta}$ cannot be too negative. However the lower bound on $M_{\Phi \Delta}$ arises from the observation that the $B$ term defined in Eq. (21) must be negative in order to attain positive $M_{\Delta}$ and $M_{\Delta}$. Note that since $v_\Delta$ and $v_\Phi$ are much larger than $v$, $B$ can then be approximated as $-2(4v_\Delta m_{H^*}^2 + M_{\Phi \Delta}(4v_\Delta^2 + v_\Phi^2))$. This means that $M_{\Phi \Delta}$ cannot be too negative. However the lower bound, $M_{\Phi \Delta} \lesssim -0.56$ GeV, also depends on the chosen range of $-1 \lesssim (M_{H \Delta}/\text{TeV}) \lesssim 1$ in the scans as it may help to cancel a negative $M_{\Phi \Delta}$. If one enlarges the scanning range of $M_{H \Delta}$, the lower bound becomes more negative.

FIG. 6. The correlations of the signal strength $\mu_{ggH}^{\gamma\gamma}$ with the squared mixing matrix element $O_{11}^2$ (upper-left) and the ratio $O_{21}^2/O_{11}$ (upper-right) is shown. The dashed line indicates the most recent ATLAS result for the central value of $\mu_{ggH}^{\gamma\gamma} = 0.81$ [39]. The light and dark gray bands indicate the $2\sigma$ and $1\sigma$ errors in $\mu_{ggH}^{\gamma\gamma}$ respectively. Below, the relative (lower-left) and absolute (lower-right) contribution to $\mu_{ggH}^{\gamma\gamma}$ from new physics and its correlation with the mass of the charged Higgs.
Before leaving this section, we discuss the impact of the measured Higgs diphoton signal strength $\mu_{\gamma\gamma}$ from the LHC. Note that a similar analysis was presented in the previous work \[13\]. We here improve our previous analysis by including effects of the new heavy fermion loops on both the Higgs production and the decay into two photons. In addition, we have also checked the Higgs to $\tau^+\tau^-$ decay channel which has a larger uncertainty (a factor of 2 or so) than the diphoton channel \[42\], as shown in Fig. 5. Note that $\mu_{\gamma\gamma}^{ggH}$ is equal to $\Gamma(h_1 \to gg)/\Gamma^{SM}(h \to gg)$, since the $h_1 \to \tau^+\tau^-$ decay width differs from the SM one by $O_{11}^2$, cancelling the total decay width ratio $\Gamma_h^{SM}/\Gamma_h^{h_1} \approx O_{11}^{-2}$. One can expect a similar behavior in other decay channels such as $b\bar{b}, W^+W^-$ and $ZZ$, which also have bigger uncertainties. We would like to come back to this point for a more complete analysis in the future, when more data are collected at the LHC.

In Fig. 6, we show the scan results of $\mu_{\gamma\gamma}^{ggH}$ versus $O_{11}^2$ (top-left panel) and $O_{21}/O_{11}$ (top-right panel), as well as the relative (bottom-left panel) and absolute (bottom-right panel) contributions from new physics to $\mu_{\gamma\gamma}^{ggH}$. The relative contribution refers to the contribution from either the charged Higgs or heavy fermions to $\mu_{\gamma\gamma}^{ggH}$ divided by the two contributions combined, while the absolute contribution denotes the individual amplitude in Eq. (65) without the common coefficient in front. The Higgs constraints alone are labeled by orange dots, while the combined (VS + PU + HP) constraints are labeled by magenta crosses. Our results indicate that our model has no problem having $\mu_{\gamma\gamma}^{ggH}$ around the experimental central value of 0.81 with the 1$\sigma$ and 2$\sigma$ errors marked by the dark and light gray regions respectively. One can see that there are also points accumulating near the SM value $\mu_{\gamma\gamma}^{ggH} = 1$, which is barely inside the 1$\sigma$ range.
In the top-left panel of Fig. 6, for $O_{11}^2 < 0.75$ we can see that the points allowed by all constraints (magenta cross) split into three branches for small $O_{11}^2$, depending on values of $O_{21}/O_{11}$. The upper, middle and lower branches correspond to $O_{21}/O_{11} > 0.5$, $-0.5 < O_{21}/O_{11} < 0.5$ and $O_{21}/O_{11} < -0.5$, respectively, as can be visually identified from the top-right panel of Fig. 6. While this ratio of $O_{21}/O_{11}$ appears several places in our $\mu_{ggH}$ calculation, this shape is mostly controlled by the heavy colored fermion contributions to the partial decay width of $h_1$ decays into two gluons in Eq. (69). This two gluon partial width is multiplied by the diphoton partial width, which also contains some less significant effects of this ratio through the heavy charged fermions as well as the charged Higgs contributions, communicating the effects of this ratio to the whole signal strength $\mu_{ggH}$ in Eq. (64).

The deviation from the SM predicted $\mu_{ggH} = 1$ has three sources: the overall factor $O_{11}^2$ in Eqs. (65) and (69), and the extra loop contributions from the new heavy fermions and charged Higgs. Figure 6 shows that the combined effects from these three factors tend to decrease the signal strength: $\mu_{ggH} \lesssim 1$. In the end, any enhancement is not strong enough to make $\mu_{ggH} > 1$ as it has to overcome the overall factor $O_{11}^2$. An important reason for $\mu_{ggH} \lesssim 1$ is that the new heavy fermion contributions (in additional to the top quark loop) cancel the dominant contribution of the SM $W^\pm$ loop for $h_1 \rightarrow \gamma\gamma$.

Furthermore, it might seem strange to find that values of $\mu_{ggH}$ do not fall sharply to the SM value of 1 as $O_{11}^2$ grows. However, upon closer inspection of Eq. (65), we notice that the charged Higgs, whether it is heavy or light, will still contribute to the diphoton channel even if $O_{11} = 1$. This is because $O_{21}$ and $O_{31}$ will be vanishing and $C_h$ in Eq. (66) becomes unity. A relatively light charged Higgs mass can indeed move $\mu_{ggH}$ away from the SM value even if the mixing is small, i.e., $O_{11}^2 \approx 1$. When all the constraints are taken into account, the contribution from the charged Higgs dominates over heavy fermion ones completely for $m_{H^\pm} \lesssim 400$ GeV, but they become comparable around $m_{H^\pm} \gtrsim 10^3$ GeV, as demonstrated by the lower-right panel of Fig. 6. It is important to note that while the lower panels of Fig. 6 apparently show an upper bound for the mass of the charged Higgs, this is actually the maximum value reached with our choice of scan range of $v_\Delta$ and has no theoretical implication on the upper limit of the charged Higgs mass.

To further illustrate the role of new physics contributions from the charged Higgs and heavy fermions in G2HDM, we compare the new contributions with the SM contributions in the loops of $\Gamma(h_1 \rightarrow \gamma\gamma)$ in Fig. 7. At the top-left panel the ratio of charged Higgs loop to SM loops is shown, while at the top-right panel we have the ratio of total contributions from new physics loops (charged Higgs plus new heavy fermions) to SM loops. At the two bottom panels we show the ratio of new heavy fermions to SM loops projected on the common heavy fermion mass (left) and charged Higgs mass (right).

Lastly, with the final allowed parameter space determined, we compute the mean values and the standard deviations for all the scalar masses using the allowed points. We thus obtain distributions for the masses of all the scalars in G2HDM. The resulting mass spreads are shown in Fig. 8, with dots indicating their mean values and error bars for the $\pm 1\sigma$ deviation. One can easily see that while the DM candidate $D$ in G2HDM has a mass around 1–3 TeV, all other scalars are much heavier ($\gtrsim 10$ TeV). Note that, while we have constrained all the quartic couplings in the scalar potential, the cubic couplings $M_{H\Delta}$ and $M_{\Phi\Delta}$ remain untamed in a very wide range. By choosing suitable ranges for these parameters, e.g., by tuning them to achieve $4AC \ll B^2$ in Eq. (20), one can give $D$ a much lighter mass.

V. SUMMARY

G2HDM was proposed to promote the discrete $Z_2$ symmetry, that ensures the stability of DM in IHDM, to a local gauge symmetry by embedding the two Higgs doublets into the fundamental representation of the new $SU(2)_H$ gauge group. In this work we have studied the theoretical constraints from vacuum stability and perturbative unitarity imposed on the scalar potential of G2HDM at tree level. The 125 GeV Higgs physics data from the LHC are also taken into account, in particular the Higgs mass and its diphoton signal strength. We have improved the G2HDM scalar potential by including two new couplings $\lambda_{H\Delta}$ and $\lambda_{\Phi\Delta}$, which were missing in our previous
Although these two new couplings do not alter the minimization conditions of the scalar potential, their impacts on the scalar mass spectrum and effects on the VS, PU and HP constraints are analyzed in detail. We have recomputed the diphoton signal strength for the 125 GeV Higgs. We have included the contributions of the new heavy fermions in G2HDM and demonstrated that their effects can be significant in the diphoton channel. The charged Higgs contribution is also found to be significant if its mass is in the range of 100 to 300 GeV. Overall the diphoton signal strength is found to be $\lesssim 1$ in G2HDM. In particular G2HDM can naturally accommodate the current ATLAS central value of 0.81 for the diphoton signal strength from gluon-gluon fusion production. We note that the corresponding central value from CMS is 1.10 which is not favorable in G2HDM with the present numerical setup in this work. However we are quoting the LHC Run II data from ATLAS and CMS in our analysis, while the combined results from both experiments are not available yet.

In Fig. 9, we summarize the allowed regions of the multidimensional parameter space projected on all the two-dimensional planes comprised of the four diagonal couplings $\lambda_{H,\Delta}$, $\lambda'_{H}$ and the four off-diagonal couplings $\lambda'_{H,\Phi,\Delta,}\lambda'_{H,\Phi}$. The upper red triangular block corresponds to (VS + PU) constraints, while the lower magenta triangular...
block corresponds to the (VS + PU + HP) constraints. The diagonal panels indicate the allowed ranges of the eight couplings. One can see that among the eight couplings only two of them $\lambda_{H\Delta}$ and $\lambda_{H\Phi}$ are significantly constrained by (VS + PU + HP). Some of the couplings like $\lambda_{H\Delta}$, $\lambda_{H\Phi}$ and $\lambda_{\Phi\Delta}$ are loosely constrained as shown clearly in Fig. 9.

We emphasize that our analysis in this work is based upon tree-level VS and PU. One loop corrections to the scalar potential in G2HDM is important as it has been demonstrated in [44,45] that such loop corrections may lead to larger potential in G2HDM. Perturbative unitarity constraints can also be improved by including the cubic scalar couplings $M_{H\Delta}$ and $M_{\Phi\Delta}$. Recently, cubic scalar couplings are found to be significantly improved by the unitarity constraints in various models beyond the SM if the center-of-mass energy is not taken asymptotically infinite [46–48]. Further improvement of our current analysis can be carried out by including renormalization group running effects for all the quartic couplings as well as the two cubic couplings. These issues are interesting but beyond the scope of this work. We would like to come back to these issues in the future.

G2HDM is an interesting variant of the popular IHDM with a neutral component in the second Higgs doublet as a DM candidate. It would be interesting to include DM constraints from cosmology, direct and indirect detections as well as collider searches in our analysis. This work is in progress [49] and we will report it elsewhere.
