Abstract: The present investigation was carried out to study the food grain production trends in different states in India based on Panel Regression Model for the period 2001-02 to 2020-2021. The results reveal that between state-to-state food grain production is highly significant the highest food grain production was registered in Uttar Pradesh followed by Punjab and Madhya Pradesh. Very lowest was registered in Kerala and Himachal Pradesh. The findings reveal that the highly significant fixed effect model was found to be suitable to study the trend and this model explains the 82 % of variations in food grain production. Over all increasing in food grain production is noted.

Keywords: Panel Regression Model, Least-Squares Dummy Variable, Fixed-Effect Model, Random-Effect Model, Wald Test, Hausman Test.

Conflicts of Interest: Authors have no Conflict of Interest

1. Introduction

Over the last few decades, regression modelling has traditionally been employed in agricultural production prediction and classification. For agricultural planning purposes, decision-makers need simple and reliable estimation techniques for crop production prediction. Multiple regressions, Discriminant analysis, factor analysis, principal component analysis, cluster analysis and logistic regression analysis are the most commonly used statistical techniques for the prediction and classification of agricultural-related production. In agricultural production time series data, the problems of multicollinearity, autocorrelation and extreme values are unavoidable. In such complex situations, regression models may not provide accurate predictions. Regression models need to fulfil regression assumptions such as autocorrelation and multiple colinearity between the independent variables, which causes the estimated regression models to be unfit and the estimated parameter values obtained based on these models to be inefficient. In most agricultural practices, crop production is influenced by a great variety of interrelated factors such as autocorrelation, and it is difficult to describe their relationships using conventional methods (Zaefizadah et al., [1]).
In this study, panel data regression model is used to combat the complicated relations and strong autocorrelation present in the crop production data.

Panel data is a combination of cross-sectional and time series data. Therefore, using a regression suited to panel data has the advantage of distinguishing between fixed and random effects. Fixed effects, effects that are independent of random disturbances, e.g. observations independent of time. Random effects, effects that include random disturbances. Panel data is more informative since it includes more information, but it has to be modeled correctly by taking into account fixed vs. random effects.

Panel data helps us to controls heterogeneity of cross-section units such as individuals, states, firms, countries etc., over time. Panel data estimation considers all cross-section units as heterogeneous. It helps us to get unbiased estimation. There are time invariant and state invariant variables which we observe or not. As compared to pure cross section and time series, panel data estimation is better to identify and measure effects of independent variables on dependent variables what we cannot measure using time series and cross section data. In addition to this “Panel data give more informative data, more variability, less colinearity among the variables, more degree of freedom and more efficiency”. It is also better estimation method to study the duration of economic states and the “dynamics of change”, over time. It is a good estimation method to ‘construct and test complicated behavioral models’, (Baltagi, [2]).

Based on the above discussion, the present study is aimed to study the trends in food grain production in different states in India over the period 2001-02 to 2020-2021 based on panel regression model.

2. Materials and Methods

2.1. Materials: The present investigation was carried out to study the trends in food grain production in India based on Panel Regression model. The cross-sectional time series data on food grain production for the period 2001-02 to 2020-2021 (twenty years) have been collected from Reserve Bank of India - Handbook of Statistics on Indian Economy (rbi.org.in). The food grain production in eighteen states of India viz. Andhra Pradesh, Karnataka, Kerala, Tamil Nadu, Gujarat, Chhattisgarh, Bihar, Haryana, Himachal Pradesh, Jharkhand, Madhya Pradesh, Maharashtra, Odisha, Punjab, Rajasthan, Uttar Pradesh, Uttarakhand and West Bengal have been considered.
2.2. **Methods:** Panel data are a type of data that contain observations of multiple phenomena collected over different time periods for the same group of individuals, units, or entities. In short, econometric panel data are multidimensional data collected over a given period.

A simple panel data regression model is specified as

\[ Y_{it} = \alpha + \beta X_{it} + \nu_{it} \] (1)

where \( \nu_{it} \) are the estimated residuals from the panel regression analysis. Here, \( Y \) is the dependent variable, \( X \) is the independent or explanatory variable, \( \alpha \) and \( \beta \) are the intercept and slope, \( i \) stands for the \( i^{th} \) cross-sectional unit and \( t \) for the \( t^{th} \) month, and \( X \) is assumed to be non-stochastic and the error term to follow classical assumptions, namely, \( E(\nu_{it}) = N(0, \sigma^2) \). In this study, \( i \), the number of cross-sections is 18 (\( i=1, 2, 3, 4, \ldots, 18 \)), and \( t=1, 2, 3, \ldots, 20 \). Detailed discussions of panel data models were given in Hsiao, [3], Greene, [4] and Gujarathi, [5].

2.2.1. **Unit Root Test:** Unit roots for the panel data can be tested using either the Levin-Lin-Chu, [6] test or the Hadri, [7] LM stationarity test. The null hypothesis is that panels contain unit roots, and the alternative hypothesis is that panels are stationary. In the results, if the \( p \) value is less than 0.05, then one can reject the null hypothesis and accept the alternative hypothesis. Similarly, the unit root for the first difference can also be tested using a similar method.

2.2.2. **Constant Coefficients Model:** The Constant Coefficients Model (CCM) assumes that all coefficients (intercept and slope) remain unchanged across cross-sectional units, and over time. In other words, the CCM ignores the space and time dimensions of panel data. Put differently, under the CCM, the cross-sectional units are assumed to be homogeneous such that the values of intercept and slope coefficients are same irrespective of cross-sectional unit being considered. Accepting this homogeneity assumption (also called pooling assumption), the CCM uses the panel (or pooled) data set, and applies Ordinary Least Squares (OLS) method to estimate unknown parameters of the model. Thus, the CCM is nothing but straightforward application of OLS to a given panel or pooled data to obtain estimates for unknown parameters of the model (Bhaumik, [8]).
### 2.2.3. Individual Specific-Effect Model:

Here, it is assumed that there is unobserved heterogeneity across individuals and captured by $\alpha_i$. The main question is whether the individual-specific effects $\alpha_i$ are correlated with the regressor; if they are correlated, a fixed effects model exists. If these factors are not correlated, a random effects model exists.

### 2.2.4. Fixed-Effect OR Least-Square Dummy Variable Regression Model:

Fixed effect regression model indicates that each unit has its own intercept. There will be heterogeneity among the unit due to individual intercepts. Here in fixed effect model the unit intercepts are time-invariant (do not vary over time) even if they might be different among cross-section units. However the fixed effect model believes that the coefficients of the independent variables do not vary across cross-section unit or over time. These fixed effects model can be implemented with the dummy variable technique. Therefore, the fixed effects model can be written as

$$Y_{it} = \alpha_i + \alpha_{2i}D_{2i} + \alpha_{3i}D_{3i} + \alpha_{4i}D_{4i} + \ldots + \alpha_{ni}D_{ni} + \beta_i X_{it} + v_{it}$$

where $D_{2i} = 1$ if the observation is from Karnataka State and is 0 otherwise, $D_{3i} = 1$ if the observation is from Kerala and is 0 otherwise, and $D_{4i} = 1$ if the observation is from Tamil Nadu and is 0 otherwise etc.. Here, $\alpha_i$ represents the intercept of Andhra Pradesh and $\alpha_2$, $\alpha_3$, and $\alpha_4$ are different intercept coefficients that indicate how much the intercepts of Karnataka, Kerala, and Tamil Nadu differ from that of Andhra Pradesh state. Since the dummies are used to estimate the fixed effects, the model is also known as the least-squares dummy variable (LSDV) model; hence, one can conclude that the restricted panel regression model is invalid and that the LSDV model is valid (Bhaumik, [8]).

### 2.2.5. Random-Effect (RE) Model:

Random effects model is also called error component model (ECM). In this model the cross section units will have random intercept instead of fixed intercept. The rationale behind random effects model is that, unlike the fixed effect model, the variation across entities is assumed to be random and uncorrelated with the predictor or independent variables included in the model, the crucial distinction between the fixed and random effects is whether the unobserved individual effects embodies elements that are correlated with regressors in the model, not whether these effects are stochastic or not (Green, [4]). The RE model assumes that individual-specific effects $\alpha_i$ are random and one
should include $\alpha_i$ in the error term. Each cross-section has the same slope parameters and a
composite error term. So the model (1) become Random-Effect Model (REM):

$$y_{it} = x_i \beta + (\alpha_i + \nu_{it})$$

Let $\epsilon_{it} = \alpha_i + \nu_{it}$.

Here $\epsilon_{it}$, $\alpha_i$, and $\nu_i$ are normally distributed with zero means and constant variances $\sigma^2_{\epsilon}$, $\sigma^2_{\alpha}$
and $\sigma^2_{\nu}$, respectively.

Hence: $\text{var}(\epsilon_{it}) = \sigma^2_{\alpha} + \sigma^2_{\nu}$, and $\text{cov}(\epsilon_{it}, \epsilon_{iu}) = \sigma^2_{\nu}$; therefore, $\rho_{\epsilon} = \text{cor}(\epsilon_{it}, \epsilon_{iu}) = \frac{\sigma^2_{\nu}}{\sigma^2_{\alpha} + \sigma^2_{\nu}}$.

Rho is the interclass correlation of the error or the fraction of the variance in the error term
due to individual-specific effects. These variable approaches 1 if individual effects dominate
the idiosyncratic error (Bhaumik, [8]).

2.2.6. Hausman test: The Hausman test (Hasman, [9]) is the standard procedure used in
empirical panel data analysis to distinguish between the fixed effects and random effects. In
the Hausman test the null hypothesis signifies that there is no significant difference in the
estimator of fixed effect model and random effect model. If we reject the null hypothesis the
fixed effect model will be the appropriate model. Rejecting the null hypothesis shows that
there might be correlation between the error term and dependent variable. The test statistic
can be calculated is given as follows:

$$H = \left( \hat{\beta}_{RE} - \hat{\beta}_{FE} \right) \left( V(\hat{\beta}_{RE}) - V(\hat{\beta}_{FE}) \right) \left( \hat{\beta}_{RE} - \hat{\beta}_{FE} \right)$$

Here, $\hat{\beta}_{RE}$ and $\hat{\beta}_{FE}$ are the vector of parameter estimates of random effect and fixed effect,
respectively. Under the null hypothesis, this statistic has asymptotically the chi-squared
distribution with the number of degrees of freedom equal to the rank of the matrix:

$$\left( V(\hat{\beta}_{RE}) - V(\hat{\beta}_{FE}) \right)$$

2.2.7. Wald Test: The Wald test (Wald, [10]) can determine which model variables make
significant contributions. The Wald test (also called the Wald chi-squared test) is a way to
determine if explanatory variables in a model are significant, meaning that they add
something to the model; variables that add nothing can be deleted without affecting the model
in a meaningful way. The test can be used for a multitude of different models, including those
with binary variables or continuous variables. The null hypothesis for the test is: some
parameter = some value.
2.2.8. Breusch-Pagan Lagrange Multiplier Test: The Breusch-Pagan-Godfrey test (Breusch and Pagan, [11]) is a Lagrange multiplier test of the null hypothesis of no heteroskedasticity, i.e., constant variance among residuals.

\textbf{Ho}: The null hypothesis of the test states that there is constant variance among residuals.

3. Results and Discussion

The results obtained in this paper based on applying different statistical tools related to panel regression models are discussed in subsequent sections.

3.1. Summary Statistics: The descriptive statistics results presented in Table 1 and depicted in Fig.1., reveal that state wise food grain production are normally distributed as indicated by Jarque-Bera statistic’s p-values except for the states Himachal Pradesh and Odisha. Highest food grain production was registered in Uttar Pradesh followed by Punjab and Madhya Pradesh. Very lowest production is registered in Kerala, and Himachal Pradesh. The Fig.2 depicts that highest food grain production is registered during year 2018-19 and the year wise production shows the increasing trend.

| Method             | Individual Effect | Individual effects, linear trends |
|--------------------|-------------------|-----------------------------------|
|                    | Statistic         | Prob.**                           | Statistic | Prob.** |
| Levin, Lin & Chu t*| 3.05481           | 0.0011                            | 9.12116   | 0.0000  |

** Probabilities are computed assuming asymptotic normality.

**Constant Coefficient Model (Panel OLS):** The CCM es method is employed considering the food grain production (PRODN) as the dependent variable and X, time, as the independent variables; the results are presented in Table 4. The result reveals that the intercepts and slopes are positive and highly significant at the 1% level of significance. The positive slope indicates that the food grain production is an increasing trend. The model is highly significant at the1% level of significance with an incredibly low $R^2$ value of 15% which is very low. Additionally, the estimated Durbin-Watson value of 0.043090 is quite low, which suggests the presence of autocorrelation in the data.
Table 4: Characteristics of the fitted panel least-squares method

| Variable | Coefficient | Std. Error | t-Statistic | Prob. |
|----------|-------------|------------|-------------|-------|
| C        | 5384.438    | 1092.674   | 4.927761    | 0.0000|
| X        | 41.81541    | 5.246203   | 7.970603    | 0.0000|
| Root MSE | 10315.66    | R-squared  | 0.150714    |       |
| Mean dependent var | 12932.12 | Adjusted R-squared | 0.148342 | |
| S.D. dependent var | 11209.18 | S.E. of regression | 10344.43 | |
| Akaike info criterion | 21.33182 | Sum squared resid | 3.83E+10 | |
| Schwarz criterion | 21.35341 | Log likelihood | -3837.728 | |
| Hannan-Quinn criter. | 21.34041 | F-statistic | 63.53052 | |
| Durbin-Watson stat | 0.043090 | Prob(F-statistic) | 0.000000 | |

The estimated model assumes that the slope coefficients of time variables X are all identical in all eighteen states. Therefore, despite its simplicity, the CCM may distort the true relationship between the dependent variable — food grain production (PRODN)—and time, the independent variable X, across the states.

**Fixed-Effect OR Least-Square Dummy Variable Regression Model:** The result presented in Table 5 reveals that the fixed effect model explains the 82% of variations in the dependent variable. The model is highly significant at 1% level of significance. All the dummy variables also highly significant at 1% level of significant. The value of root mean square error is 2609.55 with the S.E. of regression is 2681.27.

Based on the statistical significance at the 1% level of significance of the estimated coefficients and the substantial increase in the $R^2$ value to 95% (significant at the 1% level of significance), one can conclude that the fixed effects model or the LSDSV regression model performs better than the panel least-squares regression model (CCM).

Table 5: Characteristics of the fixed effects or LSDSV regression model

PRODN=C(1)+C(2)*X+C(3)*(D2)+C(4)*(D3)+C(5)*(D4)+C(6)*(D5)+C(7)*(D6)+C(8)*(D7)+C(9)*(D8)+C(10)*(D9)+C(11)*(D10)+C(12)*(D11)+C(13)*(D12)+C(14)*(D13)+C(15)*(D14)+C(16)*(D15)+C(17)*(D16)+C(18)*(D17)+C(19)*(D18)

| Coefficient | Std. Error | t-Statistic | Prob. |

| C(10)       | -57424.43  | 4011.77     | -14.31400 | 0.0000|
The cross-section fixed effects (as deviations from common intercept) in the context of fixed effect model are calculated and presented in the Table 6. The fixed effects are positive in Andhra Pradesh, Karnataka, Kerala, Tamil Nadu, Gujarat, Chhattisgarh, Bihar, Haryana and Madhya Pradesh. The fixed effect is negative in Himachal Pradesh, Jharkhand, Maharashtra, Odisha, Punjab, Rajasthan, Uttar Pradesh, Uttarakhand, and West Bengal have been considered. In Andhra Pradesh the fixed effect is 48704.08 which is highest in comparison to that of in other states.

**Table 6: Cross-Section Fixed Effects Values**

| Sr.No. | CROSSID | Effect   |
|-------|--------|----------|
| 1     | 1      | 48704.08 |
| 2     | 2      | 39104.18 |
| 3     | 3      | 23203.00 |
| 4     | 4      | 25115.36 |
| 5     | 5      | 18631.08 |
| 6     | 6      | 12708.84 |
| 7     | 7      | 13416.63 |
| 8     | 8      | 10996.32 |
| 9     | 9      | -8720.35 |
| 10    | 10     | -11899.43|

| 12    | 12     | -14281.14|
| 13    | 13     | -24484.48|
| 14    | 14     | -9947.343|
| 15    | 15     | -25864.95|
| 16    | 16     | -1893.496|
| 17    | 17     | -52167.48|
| 18    | 18     | -42766.37|
The diagrammatic representation of fixed effects in all eighteen states is depicted in Fig. 3. Based on this result it is concluded that the Fixed effect model is better than CCM.

![Fixed effect in different states](image)

**Fig.3. Fixed effect in different states**

To confirm the presence of Fixed Effect, the Redundant Fixed Effect test has been carried out and the results are presented in Table 7.

### Table 7: Results of Redundant Fixed Effects Test

| Redundant Fixed Effects Tests | Statistic   | d.f.   | Prob.  |
|------------------------------|-------------|--------|--------|
| Cross-section F              | 293.390789  | (17,341) | 0.0000 |
| Cross-section Chi-square     | 989.629016  | 17     | 0.0000 |

**PRODN=C(1)+C(2)*X**

| Coefficient     | Std. Error | t-Statistic | Prob.  |
|-----------------|------------|-------------|--------|
| C(1)            | 5384.438   | 4.927761    | 0.0000 |
| C(2)            | 41.81541   | 7.970603    | 0.0000 |

Root MSE 10315.66
Mean dependent var 12932.12
S.D. dependent var 11209.18
Akaike info criterion 21.33182
Schwarz criterion 21.35341
Hannan-Quinn criter. 21.34041
Durbin-Watson stat 0.043090
The test results reveal the Cross-section F and Chi-square statistic’s values are significant at 1 % level of significance indicates that the presence of fixed effects and it is different from one state to another.

**Wald Test:** To compare between fixed effect model with CCM, the Wald test has been carried out. The null hypothesis of the Wald test is $H_0=C(3)=C(4)=C(5)=...=C(18)=0$ i.e. all three dummy variables values are zero (there is no fixed effect). The result presented in Table 8 reveals that, since the F and Chi-square statistics values are significant at 1 % level of significance the null hypothesis $H_0=C(3)=C(4)=C(5)=...=C(18)=0$ is rejected which indicates that the values of the dummy variables are not equal to zero which confirms fixed effects or LSDV regression model is an appropriate model in comparisons to CCM.

### Table 8: Characteristics of the Wald test

| Test Statistic | Value   | df    | Probability |
|----------------|---------|-------|-------------|
| F-statistic    | 292.7218| (16, 341) | 0.0000      |
| Chi-square     | 4683.549| 16    | 0.0000      |

Null Hypothesis: $C(3)=C(4)=C(5)=C(6)=C(7)=C(8)=C(9)=C(10)=C(11)=C(12)=C(13)=C(14)=C(15)=C(16)=C(17)=C(18)=C(19)$

Null Hypothesis Summary:

| Normalized Restriction ($= 0$) | Value   | Std. Err. |
|--------------------------------|---------|-----------|
| $C(3) - C(19)$                 | 81870.55| 7887.99   |
| $C(4) - C(19)$                 | 65969.37| 7400.87   |
| $C(5) - C(19)$                 | 67881.74| 6914.19   |
| $C(6) - C(19)$                 | 61397.45| 6428.02   |
| $C(7) - C(19)$                 | 55475.22| 5942.52   |
| $C(8) - C(19)$                 | 56183.00| 5457.84   |
| $C(9) - C(19)$                 | 53762.70| 4974.23   |
| $C(10) - C(19)$                | 34046.02| 4492.03   |
| $C(11) - C(19)$                | 30866.94| 4011.77   |
| $C(12) - C(19)$                | 42911.94| 3534.22   |
| $C(13) - C(19)$                | 28485.23| 3060.65   |
| $C(14) - C(19)$                | 18281.89| 2593.25   |
| $C(15) - C(19)$                | 32819.03| 2136.06   |
| $C(16) - C(19)$                | 16901.42| 1697.37   |
| $C(17) - C(19)$                | 40872.88| 1296.10   |
| $C(18) - C(19)$                | -9401.19| 979.37    |

Restrictions are linear in coefficients.

**Random-Effect Model:** Finally, the random-effect model is estimated, and the results are presented in Table 9. The result reveal that the model is highly significant at 1 % level of significance with low $R^2$ value of 17 % with S.E. of regression 2845.515, RMSE, 2837.60. As in the case of fixed effect model, the random-effect model’s intercept and slope are highly
significant at 1 % level of significance. The rho value is 0.9385, which indicates that the
individual effects of cross-sections are 0.9%.

Table 9: Characteristics of the fitted random effects model

| Variable        | Coefficient | Std. Error | t-Statistic | Prob.  |
|-----------------|-------------|------------|-------------|--------|
| C               | -14867.17   | 3952.539   | -3.761424   | 0.0002 |
| X               | 154.0127    | 17.08422   | 9.014909    | 0.0000 |

Effects Specification

|                  | S.D.    | Rho     |
|------------------|---------|---------|
| Cross-section random | 10472.86 | 0.9385 |
| Idiosyncratic random | 2681.265 | 0.0615 |

Weighted Statistics

|                  | Value     | Description                  | Prob.  |
|------------------|-----------|------------------------------|--------|
| Root MSE         | 2837.599  | R-squared                    | 0.167746 |
| Mean dependent var | 739.1265 | Adjusted R-squared            | 0.165422 |
| S.D. dependent var | 3114.779 | S.E. of regression            | 2845.515 |
| Sum squared resid | 2.90E+09 | F-statistic                  | 72.15735 |
| Durbin-Watson stat | 0.565478 | Prob(F-statistic)            | 0.000000 |

Unweighted Statistics

|                  | Value     | Description                  |
|------------------|-----------|------------------------------|
| R-squared        | -0.934325 | Mean dependent var           |
| Sum squared resid | 8.73E+10 | Durbin-Watson stat           |

The cross-section random effects in the context of random effect model are calculated
and presented in the Table 10. The random effects are positive in Andhra Pradesh, Karnataka,
Kerala, Tamil Nadu, Gujarat, Chhattisgarh, Bihar, Haryana and Madhya Pradesh and Punjab.
The random effects are negative in Himachal Pradesh, Jharkhand, Maharashtra, Odisha,
Rajasthan, Uttar Pradesh, Uttarakhand, and West Bengal have been considered.

Table 10: Cross-Section Random Effects Values

| Sr.No. | CROSSID | Effect     |
|--------|---------|------------|
| 1      | 1       | 28307.42   |
| 2      | 2       | 21119.77   |
| 3      | 3       | 7651.421   |
| 4      | 4       | 11938.43   |
| 5      | 5       | 7856.217   |
| 6      | 6       | 4334.215   |
| 7      | 7       | 7420.576   |
| 8      | 8       | 7389.066   |
| 9      | 9       | -9882.309  |
| 10     | 10      | -10670.12  |
| 11     | 11      | 3716.420   |
| 12     | 12      | -8282.265  |
| 13     | 13      | -16071.39  |
| 14     | 14      | 799.1541   |
| 15     | 15      | -12685.57  |
| 16     | 16      | 13588.47   |
| 17     | 17      | -34140.40  |
| 18     | 18      | -22389.11  |
The diagrammatic representation of random effect in all eighteen states is depicted in Fig. 4. Based on this result the presences of random effects in all four different districts are confirmed.

**Breusch-Pagan Lagrange-Multiplier Test:**

The result presented in Table 11 indicates that the Breusch-Pagan LM, Pesaran scaled LM and Pesaran CD tests statistic values are highly significant at 1% level of significance since both statistics p-values are equal to 0.0000, indicating that the null hypothesis of the test, “H₀: There is constant variance among residuals” is rejected. Hence, the above random effect model having the problem of heteroscedasticity.

**Table 11: Characteristics of the residual cross-section dependence test**

| Test                | Statistic  | d.f. | Prob.  |
|---------------------|------------|------|--------|
| Breusch-Pagan LM    | 566.0751   | 153  | 0.0000 |
| Pesaran scaled LM   | 23.61393   |      | 0.0000 |
| Pesaran CD          | 3.092296   |      | 0.0020 |
**Hausman Test:** The Hausman test result presented in the following Table 12, reveals that the as the Chi-Sq. statistics value 0.0000 with 1 degree of freedom is highly significant at 1% value of significance, the null-hypothesis “H₀: Random Effect Model” is rejected. So, among the three models viz. CCM, Fixed effect and Random effect model, the fixed effect model is emerged as an appropriate model.

Table 12: Characteristics of the Hausman Test

| Test Summary          | Chi-Sq. Statistic | Chi-Sq.D.F. | Prob.  |
|-----------------------|-------------------|-------------|--------|
| Cross-Section Random  | 46.2043           | 1           | 0.0000 |

The following fig 5. depicts and confirms that the coefficients of intercept and slope are lying in the 99% Confidence Interval (CI)

4. **Conclusion**

The present investigation was carried out to study the food grain production trends in different states in India based on Panel Regression Model for the period 2001-02 to 2020-2021. The result reveals that between state-to-state food grain production is highly significant the highest food grain production was registered in Uttar Pradesh followed by Punjab and Madhya Pradesh. Very lowest was registered in Kerala and Himachal Pradesh. The fixed effect model was found to study the trend and this model explains the 82% of variations in food grain production. Increases in food grain production have been observed.
