COMMON BOUNDARY VALUES OF HOLOMORPHIC FUNCTIONS
FOR TWO-SIDED COMPLEX STRUCTURES

FLORIAN BERTRAND, XIANGHONG GONG*, AND JEAN-PIERRE ROSAY

ABSTRACT. Let $\Omega_1, \Omega_2$ be two disjoint open sets in $\mathbb{R}^{2n}$ whose boundaries share a smooth real hypersurface $M$ as a relatively open subset. Assume that $\Omega_i$ is equipped with a complex structure $J_i$ which is smooth up to $M$. Suppose that at each point $x \in M$ there is a vector $v \in T_xM$ such that $J_1^xv$ and $J_2^xv$ are in the same connected component of $T_x\mathbb{R}^{2n} \setminus T_xM$. If $f$ is holomorphic with respect to both structures in the open sets, then $f$ must be smooth on the union $\Omega_1 \cup M$. Although the result, as stated, is far more meaningful for integrable structures, our methods make it much more natural to deal with the general almost complex structures without the integrability condition. The result is therefore proved in the framework of almost complex structures.

1. Introduction

In this paper, we study the regularity of boundary values of two functions which are holomorphic with respect to two complex structures defined on two domains separated by a real hypersurface. We are interested in the situation where the two functions have the same continuous boundary values on the hypersurface. Notice that the regularity property becomes an interior regularity problem when the two structures are the restriction of the same complex structure, which is well established by the Newlander-Nirenberg theorem; our results are concerned with a pair of distinct structures. To highlight the relevance of our problem to yet another classical regularity problem, we recall the edge-of-the-wedge theorem, which deals with two holomorphic functions on two wedges in $\mathbb{C}^n$ that have the same appropriate boundary values on the edge. Under suitable assumptions on the

1. INTRODUCTION

In this paper, we study the regularity of boundary values of two functions which are holomorphic with respect to two complex structures defined on two domains separated by a real hypersurface. We are interested in the situation where the two functions have the same continuous boundary values on the hypersurface. Notice that the regularity property becomes an interior regularity problem when the two structures are the restriction of the same complex structure, which is well established by the Newlander-Nirenberg theorem; our results are concerned with a pair of distinct structures. To highlight the relevance of our problem to yet another classical regularity problem, we recall the edge-of-the-wedge theorem, which deals with two holomorphic functions on two wedges in $\mathbb{C}^n$ that have the same appropriate boundary values on the edge. Under suitable assumptions on the

wedges, the theorem concludes that both functions are actually the restriction of the same holomorphic function defined on a domain containing the edge. The edge-of-the-wedge theorem, originally due to Bogoljubov, has been extended in great generality by many authors. For instance, see Rudin [19] and references therein, Morimoto [14], Pinčuk [17], Bedford [1], Straube [22], Rosay [18], Forstnerič [7], and Eastwood-Graham [6]. Despite some similarity between the classical edge-of-the-wedge theorem and our results, the study of the regularity in this paper apparently gives rise to a new type of boundary regularity problem even in one complex variable. Our methods are effective to study the case of not necessarily integrable almost complex structures, and they allow us to deal with a pair of systems of non-homogeneous equations.

Our main result is the following theorem.

**Theorem 1.1.** Let \( \Omega_1, \Omega_2 \) be disjoint open subsets of \( \mathbb{R}^{2n} \) such that their boundaries \( \partial \Omega^1, \partial \Omega^2 \) share a \( C^\infty \) smooth real hypersurface \( M \). Suppose that \( M \) is relatively open in each \( \partial \Omega^l \). For \( l = 1, 2 \), let \( J^l \) be an almost complex structure of class \( C^\infty \) on \( \Omega_l \cup M \). Suppose that at each point \( x \in M \), there is a vector \( v \) tangent to \( M \) at \( p \) such that \( J_1^x v \) and \( J_2^x v \) belong to the same connected component of \( T_x \mathbb{R}^{2n} \setminus T_x M \). Let \( f \) be a continuous function on \( \Omega_1 \cup M \cup \Omega_2 \). Suppose that \( (\partial_{x_j} + i J^l \partial_{x_j}) f \) and \( (\partial_{y_j} + i J^l \partial_{y_j}) f \), originally defined on \( \Omega_l \), extend to functions of class \( C^\infty \) on \( \Omega_l \cup M \) for \( l = 1, 2 \) and \( 1 \leq j \leq n \). Then \( f \) is of class \( C^\infty \) on \( \Omega_1 \cup M \).

We will actually prove a more precise version of Theorem 1.1 under finite smoothness assumptions made on the hypersurface, the structures, and the set of the derivatives of \( f \) in the theorem. We emphasize that we make no convexity assumption on \( M \) with respect to either of the almost complex structures. Therefore, it is not clear if the smoothness of the function restricted to the hypersurface can be achieved via classical one-sided techniques such as of Bishop discs; and, although it leads to a loss of regularity, the use of the Fourier transform appears to be essential in our approach to the boundary value problem. We also point out that our results in Section 6 for one complex dimension are sharp under finite smoothness assumptions.

As mentioned earlier, the interior regularity of \( f \) for integrable almost complex structures is ensured by the well-known Newlander-Nirenberg theorem [15] (see also Nijenhuis-Woolf [16] and Webster [25]). There are results on Newlander-Nirenberg theorem for pseudoconvex domains with boundary by Catlin [4] and Hanges-Jacobowitz [9]. See earlier work of Hill [10] on failure of Newlander-Nirenberg type theorem with boundary.

As an application of our main theorem, let us observe how the common boundary values arise from the Cauchy-Green operator for \( \overline{\partial} \) in \( \mathbb{C} \). Let \( X = \partial_{\overline{z}} + a \partial_z \) with \( a, |a| < 1 \), being a \( C^\infty \) function on the closure of a bounded domain \( \Omega \) with smooth boundary in \( \mathbb{C} \). To seek new coordinates \( z + f(z) \) to transform \( \partial_{\overline{z}} + a \partial_z \) into a multiple of \( \partial_{\overline{z}} \), we consider the equation

\[
\partial_{\overline{z}} f + a(z) \partial_z f + b(z) = 0, \quad z \in \Omega.
\]

where \( b \) is \( C^\infty \) on the closure of \( \Omega \). To solve it, one considers the integro-differential equation

\[
f(z) + T(a \partial_z f)(z) + Tb(z) = 0, \quad z \in \Omega.
\]
Here $T = T_\Omega$ is the Cauchy-Green operator
\[ Tf(z) = \frac{1}{\pi} \int_{\Omega} \frac{f(\zeta)}{z - \zeta} \, d\xi \, d\eta. \]

The equation (1.2) is equivalent to (1.1) and an extra equation
\[ \int_{\partial \Omega} \frac{f(\zeta)}{\zeta - z} \, d\zeta = 0, \quad z \in \Omega. \]

When $f \in C(\partial \Omega)$, the jump formula implies that (1.3) is equivalent to $f$ being the boundary values of a function that is holomorphic on $\Omega' = \mathbb{C} \setminus \overline{\Omega}$, continuous on $\overline{\Omega}$, and vanishing at $\infty$. See Lemmas 6.3 and 6.6 for details. To find a solution $f$ that is $C^\infty$ on $\overline{\Omega}$ for the equation (1.1), we would like to invert the operator $I + T_\alpha \partial_z$ in $C^k$ space for each finite $k$.

As an application of our main result, we will prove the following.

**Theorem 1.2.** Let $0 < \alpha < 1$ and let $\Omega \subset \mathbb{C}$ be a bounded domain with $C^{1+\alpha}$ boundary. Let $a, b \in C^\alpha(\overline{\Omega})$. There exists $\epsilon_0 > 0$ such that if $\|a\|_\alpha < \epsilon_0$, then (1.2) admits a unique solution $f \in C^{1+\alpha}(\overline{\Omega})$. Assume further that $a, b \in C^{k+\alpha}(\overline{\Omega})$ and $\partial \Omega \in C^{k+\alpha}$ for an integer $k \geq 0$. Then $f \in C^{k+1+\alpha}(\overline{\Omega})$. Consequently, the linear map $I + T_\alpha \partial_z$ from $C^{k+1+\alpha}(\overline{\Omega})$ into itself has a bounded inverse.

Theorem 1.2 yields a method to solve the equation (1.2) for boundary regularity of the solutions. We will prove a version of the above theorem when the equation (1.2) depends smoothly on a parameter. As a consequence, we will obtain a $C^\infty$ version of the Riemann mapping theorem for complex structures and simply connected bounded domains with smooth boundaries in the complex plane which depend ($C^\infty$) smoothly on a parameter.

Finally, we would like to explain the condition in Theorem 1.1 that $J_2^x v, J_2^y v$ be in the same connected component of $T_x \mathbb{R}^{2n} \setminus T_x M$. In one complex variable, this condition is equivalent to $J^1, J^2$ defining the same orientation for $T_x \mathbb{R}^2$ when $x \in M$. This condition is also necessary as illustrated by the following counter-example. Let $J^1$ be the standard complex structure defined by $\partial_{\overline{z}}$ on the upper half-plane $\Omega^+$. Let $J^2$ be the complex structure defined by $\partial_{\overline{z_1}}$ on the lower half-plane $\Omega^-$. Let $M$ be the real axis, which is the boundary of both $\Omega^+$ and $\Omega^-$. Let $f$ be a holomorphic function on $\text{Im} \, z > 0$ which extends continuously to $\Omega^+ \cup M$. On $\Omega^-$, let $f(z_1) = f(\overline{z_1})$. We can find $f$ which does not extend as a $C^1$ function on $\Omega^+ \cup M$. However, for any integer $n > 1$, the validity of the assertion on the smoothness of $f$ has no obvious connection with the orientations defined by $J^1, J^2$.

It is easy to extend the above counter-example to both cases where $J^1, J^2$ define the same orientation or opposite orientations, by adding $\partial_{z_2}$ or $\partial_{\overline{z_2}}$ to the one-dimensional structures, when $n = 2$.

The paper is organized as follows.

In Section 2 we will recall some basic facts about the solution operator $T$ for $\partial \overline{\partial}$ equations for bounded domains in the complex plane. We will briefly address the invertibility of $I + T_\alpha \partial$ when $a$ has compact support in a domain $\Omega$. The invertibility for this special case will be used in Section 3 to study the interior regularity of $J$-holomorphic curves depending on a parameter.

In Section 3 we give a detailed proof of the existence and the regularity of $J$-holomorphic curves which depend on a parameter. The result is due to Nijenhuis-Woolf in [16] for the
finite smoothness case. We take the opportunity to modify their proof to treat the $C^\infty$ case in the $z$-variable, which is not in [16]. However, the authors do not know if the regularity result holds for $C^\infty$ class in the parameter variable, which is another case left open in [16].

Section 4 contains some elementary estimates for Cauchy integrals for domains depending on a parameter.

In Section 5, we will prove our main theorem by establishing a more precise finite smoothness version of Theorem 1.1. The main step of the proof is to establish the smoothness of $f$ on the common boundary $M$. It is for this step that we need the assumptions on both structures. Our basic technique is the Fourier transform applied on families of lines, or straightened curves, in $M$. We will show that the Fourier transform of $f$ on these lines will decay uniformly within the families as if $f$ is of the desired regularity. To apply the two almost complex structures, we will use the flexibility that we can attach two families of approximate $J$-holomorphic curves, one for each almost complex structure, to the same family of the lines in $M$. After we establish the regularity of $f$ on $M$, we will obtain the regularity of $f$ from one side of $M$ by using families of genuine $J$-holomorphic curves. The regularity in all variables will be obtained after we establish uniform bounds on the derivatives of $f$ on families of $J$-holomorphic curves attached to $M$. We should mention that the methods of establishing the smoothness of a function via uniform boundedness of its derivatives on families of curves have appeared in other works (for instance see Tumanov [23], Coupet-Gaussier-Sukhov [5]).

In Section 6 we treat the one complex variable case, by establishing some sharp regularity results. We will conclude the paper with some open problems.

2. Inverting $I + TA\overline{\partial}_z$

In this section, we will recall estimates on the Cauchy-Green operator $T$ and $\partial_z T$. We will discuss the inversion of $I + TA\overline{\partial}_z$ in spaces of higher order derivatives when $A$ has a small $C^\alpha$ norm. When $A$ has compact support, we can invert $I + TA\overline{\partial}_z$ and $I + TA\overline{\partial}_c$ by direct estimates. This is obtained in this section. In Section 6 we will finish the proof that $I + TA\overline{\partial}_z$ is indeed invertible when $A$ is a suitable scalar function, i.e. Theorem 1.2 is valid. In fact, we will prove a parameter version for derivatives of any order by using our main theorem and a method from [16].

We will systematically use the functions that depend on parameters as follows. To prove Theorem 1.1, we need to build up smoothness of a function via its smoothness on a web of curves and on uniform bounds of its derivatives on these curves. We will need two families of curves; one consists of real curves in $M$ and another consists of $J$-holomorphic curves intersecting $M$ transversally. We will need to study the Cauchy-Green operator $T$ on domains in $J$-holomorphic curves which depend on parameters. The regularity of $J$-holomorphic curves which depend on parameters is given by Proposition 3.7. The estimates on operators $T$ on domains depending on parameters are in Lemma 4.1.

Throughout the paper, when a parameter set $P$ is involved in $\Omega \times P$, $\Omega$ is a bounded open set in a Euclidean space and $P$ is the closure of a bounded open set in a Euclidean space. We assume that two points $a, b$ in the interior of $\overline{\Omega} \times P$ can be connected by a smooth curve in the interior of length at most $C|b - a|$. 
We now recall spaces of functions with parameter defined in [16]. Let \( C^k(\overline{\Omega}) \) denote the set of functions \( f \) such that all partial derivatives of order \( k \) are continuous functions on \( \Omega \) which extend continuously to \( \overline{\Omega} \). The usual norm on \( C^{k+\alpha}(\overline{\Omega}) \) is denoted by \( |\cdot|_{k+\alpha} \). For integers \( k, j \geq 0 \) and \( 0 \leq \alpha < 1 \), we define \( \hat{C}^{k+\alpha,j}(\overline{\Omega}, P) \) to be the set of functions \( f \) defined on \( \overline{\Omega} \times P \) such that for all integer \( 0 \leq l \leq j \), the map \( t \mapsto \partial_t^l f(\cdot, t) \) is continuous from \( P \) into \( \hat{C}^k(\overline{\Omega}) \) and such that

\[
\|f\|_{k+\alpha,j} := \max_{0 \leq l \leq j} \sup_{t \in P} |\partial_t^l f(\cdot, t)|_{k+\alpha} < \infty.
\]

Define

\[
\hat{C}^\infty(\overline{\Omega}, P) := \bigcap_{k=1}^{\infty} \hat{C}^{k,j}(\overline{\Omega}, P), \quad C^\infty(\overline{\Omega}, P) := \hat{C}^\infty(\overline{\Omega}, P).
\]

To simplify notation, the parameter set \( P \) will not be indicated sometimes.

Let \( \Omega \) be a bounded domain in \( \mathbb{C} \). The \( \partial \) solution operator \( T \) and \( S = \partial_z T \) are

\[
Tf(z) := \frac{1}{\pi} \int_{\Omega} \frac{f(\zeta)}{z - \zeta} \, d\xi \, d\eta, \quad Sf(z) := \frac{1}{\pi} p.v. \int_{\Omega} \frac{f(\zeta)}{(z - \zeta)^2} \, d\xi \, d\eta.
\]

It is well-known that \( \partial_z T \) is the identity on \( L^p(\Omega) \) when \( p > 2 \). Assume now that \( 0 < \alpha < 1 \). When \( f \in C^\alpha(\overline{\Omega}) \) and \( \partial \Omega \in C^{1+\alpha} \), one has

\[
Sf(z) = -\frac{1}{\pi} \int_{\Omega} \frac{f(\zeta) - f(z)}{(z - \zeta)^2} \, d\xi \, d\eta - \frac{f(z)}{2\pi i} \int_{\partial\Omega} \frac{d\zeta}{\zeta - z}.
\]

If \( f \) has compact support in \( \Omega \), or if \( f \in C^{k+\alpha}(\overline{\Omega}) \) and \( \partial \Omega \in C^{k+1+\alpha} \), then

\[
|Tf|_{k+1+\alpha} \leq C_{k+1+\alpha} |f|_{k+\alpha}, \quad |Sf|_{k+\alpha} \leq C_{k+1+\alpha} |f|_{k+\alpha}.
\]

See Bers [2] and Vekua [24] (p. 56). The above estimates for domains with parameter will be derived in Section 4. Recall that

\[
\partial_z Sf = S \partial_z f, \quad \partial_z Sf = \partial_z f,
\]

where the first identity needs \( f \) to have compact support in \( \Omega \).

For \( f \in \hat{C}^{k+\alpha,j}(\overline{\Omega}, P) \), define \( T f(z, t), S f(z, t) \) by (2.1) and (2.2) by fixing the parameter \( t \).

**Lemma 2.1.** Let \( k, j \geq 0 \) be two integers and let \( 0 < \alpha < 1 \). Let \( \Omega \subset \mathbb{C} \) be a bounded domain with \( \partial \Omega \in \hat{C}^{k+1+\alpha} \). Then

\[
T: \hat{C}^{k+\alpha,j}(\overline{\Omega}, P) \to \hat{C}^{k+1+\alpha,j}(\overline{\Omega}, P), \quad \|Tf\|_{k+1+\alpha,j} \leq C_{k+1+\alpha} \|f\|_{k+\alpha,j},
\]

\[
S: \hat{C}^{k+\alpha,j}(\overline{\Omega}, P) \to \hat{C}^{k+\alpha,j}(\overline{\Omega}, P), \quad \|Sf\|_{k+\alpha,j} \leq C_{k+1+\alpha} \|f\|_{k+\alpha,j},
\]

for some positive constant \( C_{k+1+\alpha} \).

**Proof.** By (2.2), we get \( S(\hat{C}^{k+\alpha,j}) \subset \hat{C}^{k,j} \). We can verify that \( \partial_t S = S \partial_t \) on \( \hat{C}^{\alpha,j} \) for \( j \geq 1 \). Thus \( S(\hat{C}^{k+\alpha,j}) \subset \hat{C}^{k+\alpha,j} \) by (2.3).

The Cauchy kernel is integrable. So \( T(\hat{C}^{0,j}(\overline{\Omega}, P)) \subset \hat{C}^{0,j}(\overline{\Omega}, P) \). Also \( \partial_t T = T \partial_t \) on \( \hat{C}^{0,j} \) for \( j \geq 1 \). The rest of assertions follows from \( \partial_t T = S \) and \( \partial_z T = 1 \). \( \square \)

By an abuse of notation, we define \( \overline{\partial}_z f = \overline{\partial}_z f \).
Lemma 2.2. Let $k, j \geq 0$ be two integers and let $0 < \alpha < 1$. Let $\Omega$ be a bounded domain in $\mathbf{C}$. Let $A \in \mathcal{C}^{k+\alpha,j}(\overline{\Omega}, P)$ be an $m \times m$ matrix. There exists $\epsilon_\alpha > 0$, depending only on $\alpha$, such that the following hold.

(i) If $\partial \Omega \subset \mathcal{C}^{1+\alpha}$ and $|A|_{a,0} < \epsilon_\alpha$, then

$$I + TA_{z_{1}} + TA_{\bar{z}_{2}}: [\partial_{\alpha, j}^{1+\alpha} (\overline{\Omega}, P)]^{m} \to [\partial_{\alpha, j}^{1+\alpha} (\overline{\Omega}, P)]^{m}$$

have bounded inverses.

(ii) If $A(\cdot, t)$ have compact support in $\Omega$ for all $t \in P$ and $|A|_{a,0} < \epsilon_\alpha$, then

$$I + TA_{z_{1}} + TA_{\bar{z}_{2}}: [\partial_{\alpha, j}^{k+1+\alpha} (\overline{\Omega}, P)]^{m} \to [\partial_{\alpha, j}^{k+1+\alpha} (\overline{\Omega}, P)]^{m}$$

have bounded inverse.

Proof. We want to show that the inverse of $I + TA_{z_{1}}$ is given by

$$L = I + \sum_{l=1}^{\infty} (-1)^{l} (T A_{l})^{l}.$$ 

Since $(T A_{l})^{l} = T A(S A)^{l-1} \partial_{z}$, we need to show that the norms of $(S A)^{l-1}$ for various derivatives tend to zero sufficiently fast. When $S$ operates on functions with compact support, it commutes with $\partial_{z}, \partial_{\bar{z}}, \partial_{t}$ somewhat. However, differentiating the operator product $(S A)^{l}$ requires counting terms efficiently as $l$ tends to infinity.

(i). Fix $0 < \theta < 1/2$. Note that

$$\| f g \|_{k+\alpha,j} \leq C_{k,j} \| f \|_{k+\alpha,j} \| g \|_{k+\alpha,j}.$$ 

By (2.5), we have $\| S A \|_{a,0} \leq C_{a} \| A \|_{a,0}$. Thus,

$$\| (S A)^{l} \|_{a,0} \leq (C_{a} \| A \|_{a,0})^{l} \leq \theta^{l}$$

if $\| A \|_{a,0}$ is sufficiently small. Then

$$\| T A(S A)^{l-1} \partial_{z} f \|_{1+\alpha,0} \leq C_{\alpha} \theta^{l-1} \| A \|_{a,0} \| f \|_{1+\alpha,0}.$$ 

This shows that for $f \in \partial_{\alpha, j}^{1+\alpha}$, the series $\sum_{l=0}^{\infty} (-1)^{l} T A(S A)^{l-1} \partial_{z} f$ converges to $L f \in \partial_{\alpha, j}^{1+\alpha}$. Moreover, $\| L f \|_{1+\alpha,0} \leq C \| f \|_{1+\alpha,0}$. It is straightforward that $L(1 + TA_{z_{1}})$ and $(1 + TA_{\bar{z}_{2}}) L$ are the identity on $\partial_{\alpha, j}^{1+\alpha}$. This verifies (i) for $j = 0$. The case of $j > 0$ will follow from the argument in (ii) below, by using $\partial_{T} = T \partial_{t}$ and $\partial_{S} = S \partial_{t}$.

(ii). We need to show that $\sum \| (S A)^{l} \|_{k+\alpha,j}$ converges when $A$ has compact support in $\Omega$. Denote by $C_{k+\alpha,j}$ a positive constant depending only on $k, j$, and $\| A \|_{k+\alpha,j}$. By (2.4) and $\partial_{S} = S \partial_{t}$, we can write

$$\partial_{S} A = \hat{S} \hat{\partial} A,$$

where $\hat{S}$ is either $S$ or $I$, and $\partial, \hat{\partial}$ are of form $\partial_{z}, \partial_{\bar{z}}$, or $\partial_{t}$. Denote by $\partial^{K}$ a derivative in $z, \bar{z}$ of order $|K|$. Then $\partial(S A)^{l}$ equals a sum of terms of the form

$$S_{m_{1}}(\partial^{K_{1}} A) \cdots S_{m_{t}}(\partial^{K_{l}} A) \partial^{K_{l+1}} A, \quad |K_{1}| + \cdots + |K_{l+1}| = 1.$$ 

Here $S_{m_{i}}$ is either $S$ or $I$; in particular, $\| S_{m_{i}} \|_{k+\alpha,j} \leq C_{k+\alpha,j}$ for all $m_{i}$. The sum has at most $l + 1$ terms. Thus $\partial^{K}(S A)^{l}$ is a sum of at most $(l + 1)^{|K|+|l|}$ terms of the kind

$$S_{m_{1}}(\partial^{K_{1}} \partial^{l_{1}} A) \cdots S_{m_{t}}(\partial^{K_{l}} \partial^{l_{l}} A) S_{m_{l+1}} \partial^{K_{l+1}} \partial^{l_{l+1}}.$$ (2.6)

We extend \( \alpha, j \in \mathbb{N} \). With \( C_{\alpha} \geq 1 \),
\[
\| \partial^k \partial_l^t ((SA)^I f) \|_{k,0} \leq (l+1)^{k+j} C_{\alpha} (1 + \| A \|_{k,0} )^{k+j} \| A \|_{k,0} \| f \|_{k,0},
\]
This shows that \( \| (SA)^I \|_{k,0} \leq C_{k,0} (1 + 1)^{k+j} \theta^{l-k-j} \). Hence
\[
\| TA(SA)^I \partial_z \|_{k+1,0} \leq C_{k,0} (1 + 1)^{k+j} \theta^{n-k-j}.
\]
We conclude that \( \| (I + TA \partial_z)^{-1} \|_{k+1,0} < \infty \).

The proof for \( I + TA \overline{\partial_z} \) is obtained by minor changes. Indeed, denoting by \( C f = \overline{f} \) the complex conjugation, we write \( (TA \overline{\partial_z})^I = TAC(SA)^I \partial_z \). We have \( \partial'_2 C = C \partial_2 \) and \( \partial_2 C = C \partial_2 \), and since we may assume that \( t \) are real variables, we also have \( \partial'_2 C = C \partial_2 \). Thus \( \partial^k \partial_l^t (SAC)^n \) is a sum of at most \( (l+1)^{|l|+|t|} \) terms of the form
\[
S_m(\partial^k \partial_l^t A) C \ldots S_m(\partial^k \partial_l^{t+l-1} A) C \partial^k \partial_l^{t+l-1}.
\]
Substitute the above for \( (2.6) \). The remaining argument follows easily. \( \square \)

We need a simple version of Borel theorem with parameter.

**Lemma 2.3.** Let \( N \) be a positive integer or \( \infty \). Let \( 0 \leq j < \infty \) be an integer and \( 0 \leq \alpha < 1 \). Let \( \epsilon_k \) be positive numbers for \( 1 \leq k < N \) and let \( \epsilon_N = 0 \) for \( N < \infty \). Let \( f_I \in \mathcal{C}_N^{|I|+\alpha,j}(\mathbb{R}^n, P) \) for \( 0 \leq |I| < N \) with \( I = (i_1, \ldots, i_m) \). Assume that all \( f_I(\cdot, t) \) have support contained in a compact subset \( K \) of the unit ball \( B^n \). There exists \( E f \in \mathcal{C}_N^{N-1+\alpha,j}(\mathbb{R}^n \times \mathbb{R}^m, P) \) such that \( \partial^t E f(x,0,t) = f_I(x,t) \). Moreover, \( E f(\cdot, t) \) have compact support in the unit ball of \( \mathbb{R}^n \times \mathbb{R}^m \) and
\[
|E f|_{k+\alpha,j} \leq \epsilon_{k+1} + C_{N,k,K} \sum_{|I| \leq k} |f_I|_{k-|I|+\alpha,j}, \quad 0 \leq k < N.
\]
Here \( C_{N,k,K} \) depends also on \( \epsilon_1, \ldots, \epsilon_k \) and the upper bound of \( |f_I|_{k-|I|+\alpha,j} \) for \( |I| \leq k \).

**Proof.** We extend \( f \) one dimension at a time. Start with \( m = 1 \). We consider an extension of the form
\[
Ef(x,y,t) = \sum_{l<N} \frac{y^l}{l!} g_l(x,t) g(\delta_t^{-1} y),
\]
where \( g_l \) is a smooth function of compact support in \((-1,1)\) and \( g(1) = 1 \) for \( |y| < 1/2 \). We will also choose \( \delta_t \) which decreases to 0 so rapidly that \( Ef \) is in \( \mathcal{C}_N^{N-1+\alpha,j} \) and \( (2.7) \) holds. Here \( y^l g_l(x,y,t) \) is a substitute of \( y^l f_l(x,t) \) such that \( y^l g_l(x,y,t) \) is in \( \mathcal{C}_N^{N-1+\alpha,j} \). We also need the correct \( l \)-th \( y \)-derivative of \( y^l g_l(x,y,t) \) due to the presence of \( y^l g_l(x,y,t) \) for \( l' < l \).

Denote by \( B_\delta^n \) the open ball in \( \mathbb{R}^n \) centered at the origin with radius \( 0 < \delta < \frac{1}{2} \text{dist}(K, \partial B^n) \). Let \( g \) be a smooth function on \( \mathbb{R}^n \) with support in \( B_\delta^n \) satisfying \( \int_{\mathbb{R}^n} g(y) dy = 1 \). With \( a_l \in \mathcal{C}_N^{N-1+\alpha,j} \) to be determined, consider
\[
g_l(x,y,t) = \int_{\mathbb{R}^n} a_l(x - yz, t) \phi(z) dz.
\]
Fix t. We first consider l ≤ k < N. For |I| = k and y ≠ 0, we have
\begin{equation}
\partial^l(y^l g_l(x,y,t)) = \sum_{i_1 + |I_2| = k} C_{i_1 I_2} \frac{\partial^{i_1} y^l \partial^{|I_2|}}{y^{i_1} \partial^{I_2}} \int a_l(x - yz, t) \phi(z) \, dz
\end{equation}
with i_1 ≤ l. Write I_2 = I_3 + I_4 with |I_3| = k - l and |I_4| = l - i_1. We have
\begin{equation}
\partial^l g_l(x,y,t) = \sum_{|I| = |I_3|} \int \partial^L a_l(x - yz, t) \phi_{I_3L}(z) \, dz
\end{equation}
for some \( \phi_{I_3L} \) with support in \( B^n_0 \). When y ≠ 0, changing variables and taking derivative \( \partial^l \), we get
\begin{equation}
\partial^l g_l(x,y,t) = \sum_{|I| = |I_3|} \int \frac{1}{y^{l|I_4|+n}} \partial^L a_l(z, t) \phi_{I_3L}(\frac{x - z}{y}) \, dz.
\end{equation}
Changing variables again, we get
\begin{equation}
y^{l|I_4|} \partial^l g_l(x,y,t) = \sum_{|I| = |I_3|} \int \partial^L a_l(x - yz, t) \phi_{I_3L}(z) \, dz.
\end{equation}
The right-hand side and its derivatives in t of order at most j are clearly continuous functions. Then by (2.9), \( b_l(x,y,t) := y^l g_l(x,y,t) \) are of class \( C^{k+\alpha,j} \) for \( l ≤ k \). This shows that \( b_l ∈ \hat{C}^{N-1+\alpha,j} \) for all l. By the product rule, at \( y = 0 \)
\begin{equation}
\partial^l_y b_l(x,y,t) = l a_l(x,t), \quad \partial^l_y b_l(x,y,t) = 0, \quad l' < l.
\end{equation}
Starting with \( a_0 = f_0 \), we find \( a_l ∈ \hat{C}^{N-1-l+\alpha,j} \) inductively such that \( \partial^l_y \sum_{l' ≤ l} b_{l'}(x,y,t) \) equals \( l! f_l(x,t) \) at \( y = 0 \). We also have
\begin{equation}
\|b_l\|_{l+\alpha,j} ≤ C_{l,K} \|a_l\|_{\alpha,j}.
\end{equation}
Without loss of generality, we may assume that \( ε_l \) decreases. We choose small \( δ_l \) with \( 0 < δ_l < 1/m \) such that \( \tilde{b}_l(x,y,t) := y^l g_l(x,t) g(δ_l^{-1} y) \) satisfies
\begin{equation}
\|\tilde{b}_l\|_{l+\alpha,j} ≤ 2^{-l} ε_l.
\end{equation}
Let \( Ef \) be defined by (2.8). The estimate (2.7) is then immediate and \( Ef \) is in \( \hat{C}^{N-1+\alpha,j} \) and satisfies \( \partial_y^l Ef(x,y,t) = f_l(x,t) \) for \( l ≤ N \).

For \( m > 1 \), set \( y = (y', y_m) \) and \( y' = (y_1, \ldots, y_{m-1}) \). Suppose that we have found extensions \( f_l ∈ \hat{C}^{N-1-l+\alpha,j}(\mathbb{R}^n × \mathbb{R}^{m-1}, P) \) such that \( \partial_y^{l'} f_l = f_{l'l} \) at \( y' = 0 \) for all \( |l'| < N - l \) and
\begin{equation}
\|\tilde{f}_l\|_{k-l+\alpha,j} ≤ ε_{k+1, K} + C_{k,K} \sum_{|I'| ≤ k-l} \|f_{l'I'}\|_{k-|I'| - l+\alpha,j}, \quad k < N,
\end{equation}
where \( ε_{k,K} > 0 \) will be determined later. Moreover, assume that \( \tilde{f}_l(\cdot,t) \) have support in a compact subset \( K' \) of the unit ball of \( \mathbb{R}^{n+m-1} \), where \( K' \) depends only on \( K \). Using the one-dimensional result again, we get \( Ef ∈ \hat{C}^{N-1+\alpha,j}(\mathbb{R}^n × \mathbb{R}^{m}, P) \) with compact support in the unit ball of \( \mathbb{R}^{n+m} \). Furthermore, \( \partial_{y_m}^l Ef = \tilde{f}_l \) at \( y_n = 0 \) and
\begin{equation}
\|Ef\|_{k+\alpha,j} ≤ ε_{k+1, K} + C_{k,K} \sum_{0 ≤ l ≤ k} \|\tilde{f}_l\|_{k-l+\alpha,j}, \quad k < N.
\end{equation}
Choose \( c'_{k+1,K} > 0 \) small enough to ensure that combining the above inequality with (2.10) yields (2.7).

The above proof for non-parameter case is in [11] (pp. 16 and 18). When \( f \) is defined on \( y_n \leq 0 \) with \( \partial_{x_n}^k f = f_k \) on \( y_n = 0 \), the above extension \( Ef \) can be replaced by \( f \) on \( y_n \leq 0 \). The same conclusions on \( Ef \) hold. Seeley [21] has a linear extension \( E: C^\infty(\mathbb{R}^n_+) \to C^\infty(\mathbb{R}^n) \) such that \( E: C^k(\mathbb{R}^n_+) \to C^k(\mathbb{R}^n) \) have bounds depending only on \( k \).

3. J-holomorphic curves and derivatives on curves

This section is mainly devoted to the study of J-holomorphic curves with parameter. The result is essentially in the work of Nijenhuis-Woolf [16]. See also Ivashkovich-Rosay [12] for another regularity proof and existence of J-holomorphic curves with prescribed jets. The proof below relies only on some basic facts about the Cauchy-Green operator and the inversion of \( I + TA\bar{\partial}_f \) discussed in Section 2. We also study how to obtain the smoothness of a function from its smoothness on a web of curves and uniform bounds of its derivatives on the curves (see Proposition 3.9). This result will be one of main ingredients in the proof of Theorem 1.1. Our results are local. Throughout the paper, a real hypersurface \( M \) will be a relatively open subset of the boundary of a domain \( \Omega \subset \mathbb{R}^{2n} \), or a closed subset without boundary in the domain.

Definition 3.1. Let \( k \geq 0 \) be an integer and let \( 0 < \alpha < 1 \). We say that an almost complex structure \( J \) of class \( C^{k+\alpha} \) on \( \Omega \) (resp. \( \Omega \cup M \)) is defined by \( n \) vector fields \( X_1, \ldots, X_n \) if \( X_i \)'s and their conjugates are pointwise \( \mathbf{C} \)-linearly independent on \( \Omega \) (resp. \( \Omega \cup M \)) and \( X_i \)'s are of class \( C^{k+\alpha} \) on \( \Omega \) (resp. \( \Omega \cup M \)).

Note that for \( p \in \Omega \), \( J_p := J(p) \) is defined to be the linear map on \( T_p \Omega \) (resp. \( T_p(\Omega \cup M) \)) such that \( v + iJ_pv \) is in the linear span of \( X_1(p), \ldots, X_n(p) \) for any \( v \in T_p \Omega \) (resp. \( T_p(\Omega \cup M) \)). The operator norm \( \| A \| \) of a linear map \( A: T_p \Omega \to T_p \Omega \) is defined as \( \max\{ |Av|: |v| = 1 \} \) with \( |a\partial_x + b\partial_y| = (\sum_{i=1}^2 |a_i|^2 + |b_i|^2)^{\frac{1}{2}} \) being the Euclidean norm on \( T_p \Omega \).

Definition 3.2. We say that a diffeomorphism \( \varphi \) transforms \( X_1, \ldots, X_n \) into \( \tilde{X}_1, \ldots, \tilde{X}_n \), if \( d\varphi(X_l) \) are locally in the span of \( \tilde{X}_1, \ldots, \tilde{X}_n \).

A linear complex structure \( J \) on \( \mathbb{R}^{2n} \) is given by

\[
X_l = \sum_{1 \leq s \leq n} (b_{ls}\partial_{z_s} + a_{ls}\partial_{\bar{z}_s}), \quad l = 1, \ldots, n,
\]

where constant matrices \( A := (a_{ls}) \) and \( B := (b_{ls}) \) satisfy

\[
\begin{vmatrix}
B & A \\
A & B
\end{vmatrix} \neq 0.
\]

The map \( z = w\bar{B} + \bar{w}A \) transforms \( \partial_{z_1}, \ldots, \partial_{z_n} \) into \( X_1, \ldots, X_n \), and hence \( J_{st} \) into \( J \) given by

\[
J = KJ_{st}K^{-1}, \quad J_{st} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad K = \begin{pmatrix} \text{Re}(B + A) & \text{Im}(A - B) \\ \text{Im}(A + B) & \text{Re}(B - A) \end{pmatrix}.
\]
Thus under a local change of coordinates by shrinking $\Omega$ or $\Omega \cup M$, an almost complex structure $J$ is locally given by
\begin{equation}
X_l = \partial_{z_l} + \sum_{1 \leq s \leq n} a_{ls}(z) \partial_{z_s}, \quad l = 1, \ldots, n, \tag{3.3}
\end{equation}
where the operator norm of $A = (a_{ls})$ satisfies $\|A(z)\| < 1$ on $\Omega$ (resp. $\Omega \cup M$). Conversely, notice that the condition $\|A\| < 1$ ensures that $n$ vector fields of the form (3.3) define an almost complex structure.

In the next lemma, we give a quantitative condition and a geometric condition, with each ensuring the assumption made on the two almost complex structures in Theorem 1.1.

**Lemma 3.3.** Let $J^1, J^2$ be two linear complex structures on $\mathbb{R}^{2n}$. Let $M$ be a hyperplane in $\mathbb{R}^{2n}$. If $\|J^2 - J^1\| < 2$ or if $T_0M \cap J^1 T_0M \neq T_0M \cap J^2 T_0M$ then there exists $v \in T_0M$ such that $J^1 v, J^2 v$ are in the same connected component of $T_0 \mathbb{R}^{2n} \setminus T_0M$.

**Proof.** Denote by $T_0(M, J^l) := T_0M \cap J^l_0 T_0M$ the $J^l$-holomorphic tangent space at the origin for $l = 1, 2$. Let $\omega_1, \omega_2$ be the two connected components of $T_0 \mathbb{R}^{2n} \setminus T_0M$. Note that $J^l$ sends one of two connected components of $T_0M \setminus T_0(M, J^l)$ into $\omega_1$ and the other into $\omega_2$. Thus the assertion is trivial if $T_0(M, J^1) \neq T_0(M, J^2)$. Assume that they are identical. By choosing an orthonormal basis for $T_0 \mathbb{R}^{2n}$, we may assume that $T_0(M, J^1) = \{x_n = y_n = 0\}$.

Since $M$ contains $x_n = y_n = 0$, then $M$ is defined by $ax_n + by_n = 0$ with $a^2 + b^2 = 1$. After a change of orthonormal coordinates, $M$ and $T_0(M, J^1)$ are defined by $y_n = 0$ and $x_n = y_n = 0$ respectively. We still have $\|J^2 - J^1\| < 2$ since orthogonal transformations preserve the operator norm. Now write
\[ J^l \left( \begin{array}{c} \partial_{x'}^{(l)} \\ \partial_{y'}^{(l)} \end{array} \right) = B_l \left( \begin{array}{c} \partial_{x'} \\ \partial_{y'} \end{array} \right), \quad J^l \left( \begin{array}{c} \partial_{x_n}^{(l)} \\ \partial_{y_n}^{(l)} \end{array} \right) = C_l \left( \begin{array}{c} \partial_{x_n} \\ \partial_{y_n} \end{array} \right) + D_l \left( \begin{array}{c} \partial_{x_n} \\ \partial_{y_n} \end{array} \right), \]
where $B_l, C_l, D_l$ are real matrices, $x' = (x_1, \ldots, x_{n-1})$ and $y' = (y_1, \ldots, y_{n-1})$. In particular, $D_2^2 = -I$. We want to show that the coefficients of $\partial_{y_n}$ in $J^l \partial_{x_n}$ have the same sign. Otherwise, we can write
\[ D_1 = \begin{pmatrix} a_1 \\ -a_2 \\ 1+ a_2 \end{pmatrix}, \quad D_2 = \begin{pmatrix} a_1 \\ -a_2 \\ 1+ a_2 \end{pmatrix}, \quad b_1 > 0, \quad b_2 > 0. \]

Since $\|D_2 - D_1\| < 2$ we have $b_1 + b_2 < 2$ and $b_1^{-1} + b_2^{-1} < 2$ which is a contradiction. \[ \square \]

It is easy to see that when $n = 1$ the condition that $J^1 v$ and $J^2 v$ to be on the same side of $M$ for some $v \in T_0M$ is equivalent to that $J^1, J^2$ define the same condition for $\mathbb{R}^2$. In higher dimensions, whether $J^1, J^2$ define the same orientation or not is not related to the validity of assertions in Theorem 1.1.

**Example 3.4.** Lemma 3.3 and Theorem 1.1 fail easily for the triplet $\{J_{st}, -J_{st}, \{y_1 = 0\}\}$.

Note that $J_{st}$ and $-J_{st}$ define the same orientation if and only if $n$ is even. On the other hand, Theorem 1.1 is valid for $\{J_{st}, J_{st}^2 \times (-J_{st}^{2n-2}), \{y_1 = 0\}\}$. 
Here $J_d^{2k}$ denotes the standard complex structure on $\mathbb{R}^{2k}$. A less trivial example is given by the following. Let $0 \leq t \leq \pi$, and let $J^t$ be defined by
\[ X^t_1 = (\cos t \partial_x + \sin t \partial_y) + i \partial_z, \quad X^t_2 = (-\sin t \partial_x + \cos t \partial_y) + i \partial_z. \]

The conclusions in Lemma 3.3 and Theorem 1.1 fail for \{J^0, J^\pi, \{y_2 = 0\}\} with $\|J^0 - J^\pi\| = 2$. Under new orthonormal coordinates $u_1 = (x_2 + iy_1)/\sqrt{2}$, $w_2 = (-x_1 + iy_2)/\sqrt{2}$, $J^t$ is given by
\[
(1 + \sin t)\partial_{u_1} - \cos t \partial_{w_2} - (1 - \sin t)\partial_{w_1} - \cos t \partial_{w_2},
\]
\[
\cos t \partial_{\bar{u}_1} + (1 + \sin t)\partial_{\bar{w}_2} + \cos t \partial_{\bar{w}_1} - (1 - \sin t)\partial_{\bar{w}_2}.
\]

The above can be put into the form (3.3) with
\[
A^t_1 = \begin{pmatrix} 0 & -\cos t \\ \cos t & 0 \end{pmatrix} \frac{1}{1+\sin t}.
\]

Note that $\|A^t\| \leq 1$. However, the authors do not know if Theorem 1.1 or Lemma 3.3 holds for two structures $J^1, J^2$ of the form (3.3) with corresponding $\|A^t\| < 1$ for $t = 1, 2$. Note that such an almost complex structure preserves the standard orientation of $\mathbb{C}^n$.

**Definition 3.5.** Let $J$ be an almost complex structure defined by vector fields $X_1, \ldots, X_n$ of class $C^{k+\alpha}$ on $\Omega$ with $k \geq 0$ and $0 < \alpha < 1$.

(i) A $C^1$ map $u: \mathbb{D} \to \Omega$ is called a $J$-holomorphic curve if $du(\partial_x)$ is in the span of $X_1, \ldots, X_n$, namely if
\[
du = V(\zeta) \cdot X(u(\zeta)) = V_1(\zeta) X_1(u(\zeta)) + \cdots + V_n(\zeta) X_n(u(\zeta)).
\]

(ii) Let $k \geq 1$. A $C^1$ map $u: \mathbb{D}^+ \to \Omega$ is called an approximate $J$-holomorphic curve of order $k$ attached to the curve $u(x, 0)$, if
\[
du = V(\zeta) \cdot X(u(\zeta)) + F(\zeta) \cdot \overline{X(u(\zeta))}, \quad |F(\zeta)| = o(|\text{Im } \zeta|^{k-1}).
\]

As emphasized earlier, we may assume that $J$ is locally given by vector fields of the form (3.3). Therefore locally, a $J$-holomorphic curve $u: \mathbb{D} \to \Omega$ satisfies the following equations
\[
\partial_u u_l = \sum_{1 \leq s \leq n} a_{ls}(u) \partial_x u_s, \quad l = 1, \ldots, n
\]
which can be written as a row vector
\[
\partial_u u = \overline{\partial_u A}(u).
\]

Note that one cannot prescribe the boundary for a $J$-holomorphic disc. However, we can prescribe the boundary of the approximate $J$-holomorphic disc, defined above. This fact will be used in the proof of Theorem 1.1. Also, notice that if $f$ is a function on $\Omega$ and $u$ is an approximate $J$-holomorphic curve the above equation (3.4) implies that
\[
\partial_u f(u(\zeta)) = V(\zeta) \cdot (X f)(u(\zeta)) + F(\zeta) \cdot (\overline{X f})(u(\zeta)).
\]

When $u$ is $J$-holomorphic, this identity becomes
\[
\partial_u f(u(\zeta)) = (X f)(u(\zeta)) \cdot \overline{u}.
\]

The next two results deal with the existence of the two types of curves in Definition 3.5.
Lemma 3.6. Let $k \geq 0$ be an integer or $k = \infty$, and let $0 \leq \alpha < 1$. Let $J$ be an almost complex structure of class $\mathcal{C}^{k+\alpha}(\Omega)$ defined by vector fields

$$X_l = \sum_{1 \leq s \leq n} b_{ls} \partial_{zs} + \sum_{1 \leq s \leq n} a_{ls} \partial_{zs}, \quad l = 1, \ldots, n.$$ 

Set $A := (a_{ls})$ and $B := (b_{ls})$. Let $k' \geq 0$ and $0 \leq j < \infty$ be such that $j + k' \leq k$, and let $0 < r < 1$. Let $\bar{\Omega}$ be a compact subset of $\Omega$ and assume that $u_0 := (1,1) \times P \to K$ is a map of class $\bar{\mathcal{C}}^{k'+1+\alpha,J}(\Omega)$ such that $u_0$ maps $[-r,r] \times [-\delta, \delta] \times P \to \bar{\Omega}$ of class $\bar{\mathcal{C}}^{k'+1+\alpha,j}([-r,r] \times [-\delta, \delta], P)$ satisfying the following:

(i) $u(x,0,t) = u_0(x,t)$ and

$$du(\partial_{\zeta}) = V(\zeta, t) \cdot X(u(\zeta, t)) + F(\zeta, t) \cdot X(u(\zeta, t)),$$

(3.6)

$$|F(\zeta, t)| = o(|y|^{k'}), \quad \alpha = 0; \quad |F(\zeta, t)| = O(|y|^{k+\alpha}), \quad 0 < \alpha < 1,$$

where $\zeta = x + iy$.

(ii) Let $e_{j'+1} > 0$. On $[-r,r] \times [-\delta, \delta] \times P$ the norms of $u, V$ and $F$ satisfy

$$\|u\|_{J^j+1+\alpha,j} + \|V,F\|_{J^j+\alpha,j} \leq C_{j'+1}^* \max(\|u_0\|_{J^j+1+\alpha,j}, \|u_0\|_{J^j+1+\alpha,j} + e_{j'+1}), \quad j' < k' + 1.$$ 

Moreover, $C_{0}^*(1+\|u_0\|_{1,0})\delta > 1$ and $C_{j'+j}^*$ depends on $K, \Omega, |J|_{j'+\alpha}$ and $\inf_{\bar{\Omega}} \left\| \begin{pmatrix} A & B \\ \bar{A} & \bar{B} \end{pmatrix} \right\|$. 

Proof. We suppress the parameter $t$ in all expressions. We first determine a unique set of coefficients $a_j(x)$ for $1 \leq j' < k' + 2$ such that as a power series in $y$, $u(x,y) = u_0(x) + \sum_{j' \geq 1} a_j(x)y^{j'}$ satisfies (3.6)-(3.7). It is convenient to consider $u$ as the real map $(x,y) \mapsto (\text{Re}u, \text{Im}u)$ still denoted by $u$, and to rewrite the equations as

$$du(\partial_{\gamma}) = J(u)(du(\partial_{\gamma})) + F_1(x,y) \cdot \partial_{\gamma}, \quad F_1(x,y) = o(|y|^{k'}).$$

Here $\partial_{\gamma} = (\partial_{u_{1}}, \ldots, \partial_{u_{2n}})$ is evaluated at $u(\zeta, t)$. In the matrix form, let $J$ be the matrix defined by (3.2). Then we need to solve

$$\partial_{\gamma}u = \partial_{x}u J(u) + F_2(x,y), \quad |F_2(x,y)| = o(|y|^{k'}).$$

We solve the equation formally, which determines $a_j(x)$ uniquely for $1 \leq j' < k' + 2$, and then apply Lemma 2.3. This gives a map $u : (-r,r] \times [-1,1] \times P \to \mathbb{R}^n$ of class $\bar{\mathcal{C}}^{k'+1+\alpha,j}$ satisfying the stated norm estimate in (ii). By $|u(x,y) - u(x,0)| \leq C_0^*(\|u_0\|_{1,0} + e_1)|y|$ and the compactness of $K$, we find $\delta > 0$ such that $u$ maps $[-r,r] \times [-\delta, \delta] \times P$ into $\bar{\Omega}$. We have obtained (3.8). Thus

$$2du(\partial_{\gamma}) = du(\partial_{\gamma}) + i du(\partial_{\gamma}) = du(\partial_{\gamma}) + i J(u)(du(\partial_{\gamma})) + i F_1(x,y) \cdot \partial_{\gamma}.$$ 

Note that $du(\partial_{\gamma}) + i J(u)(du(\partial_{\gamma})) = V_1(z) \cdot X(u(z))$. Write $\partial_{\gamma}$ in terms of $X_1$’s and $\overline{X}_1$’s by using the inverse of $\left( \begin{pmatrix} B & A \\ \bar{A} & \bar{B} \end{pmatrix} \right)$ where $A$ and $B$ are given by (3.1). We get (3.6) and (3.7).

Finally we can estimate the norms of $V$ and $F$ via $V_1, F_1, F_2$ and the inverse of $\left( \begin{pmatrix} B & A \\ \bar{A} & \bar{B} \end{pmatrix} \right)$. \qed
Moreover, since the result is purely local, we may assume that $u$ point of $X$ fields $J$.

In particular, if $f$ One can see that we also define $\phi$.

Proof. We also define $\phi$.

In particular, if $f \in C^{k,\alpha}\cap C^1$ and $u \in C^{k,\alpha}\cap (\Omega, P)$, then $f \circ u \in C^{k,\alpha}\cap (\Omega, P)$ whenever the composition is well-defined. In general, for $\varphi(x, t) = (\tilde{\varphi}(x, t), t)$ with $\tilde{\varphi}$ being a map from $\Omega \times P$ into $\Omega$ of class $C^{k,\alpha}\cap C^1$, we have

$$
|v \circ \varphi|_{k,\alpha,j} \leq C(1 + |\varphi|_{1,0} + |\tilde{\varphi}|_{k,\alpha,j})^{1+k+j}|v|_{k,\alpha,j}.
$$

Let $D$ be the unit disc in $C$, $D_r$ the disc of radius $r > 0$, and $D_r^+ = D_r \cap \{\text{Im } z > 0\}$. The following result gives coordinate maps in $J$-holomorphic curves. To estimate the Cauchy-Green operator $T$ on domains in $J$-holomorphic curves, we will also need to reparametrize the $J$-holomorphic half-discs, which are obtained by cutting a $J$-holomorphic disc by the real hypersurface $M$. The reparameterization, which is not necessary $J$-holomorphic, is given by a mapping $R(\cdot, t)$ which send $D_r^+$ onto the half-discs. The existence and regularity of $J$-holomorphic curves for finite smoothness case is proved by Nijenhuis and Woolf ([16], pp. 459-460). They also stated a version of $J$-holomorphic curves with parameter passing through the same point ([16], p. 461). Since the following precise result is needed for our main results, we prove it in detail. We will also deal with $C^\infty$ structures.

**Proposition 3.7.** Let $k \geq 1$ be an integer or $k = \infty$ and let $0 < \alpha < 1$. Let $j \leq k$ be an integer. Let $J$ be an almost complex structure of class $C^{k,\alpha}$ defined on $\Omega$ by vector fields $X_1, \ldots, X_n$. Let $M \subset \Omega$ be a $C^{k+1,\alpha}$ real hypersurface containing the origin 0. Let $e: M \to C^n$ be a $C^k$ map such that $e \cdot X = e_1 X_1 + \cdots + e_n X_n$ is not tangent to $M$ at each point of $M$. Then there exist two $C^1$ diffeomorphisms $u$ and $R$ from $D_r^+$ onto their images in $\Omega$ satisfying the following:

(i) For each $t \in D_r^{n-1}$, $u(\cdot, t)$ is $J$-holomorphic and embeds $D_r$ onto $D(t)$.

(ii) $u(0, t) \in M$ and $D(t)$ intersects $M$ transversally along a curve $\gamma(t)$. Also, $u(0) = 0$ and $du(0, t)(\partial \gamma) = (e \cdot X)(u(0, t))$.

(iii) $R(\cdot, t)$ respectively sends $D_r^+ \cap M$, $(-r, r), D_r$ into $\Omega^+ \cap D(t), M \cap D(t), D(t)$ and satisfy $R(0) = 0$.

(iv) Moreover $u$ and $R$ are in $C^{k+1+\alpha,j}(D_r, D_r^{n-1})$.

**Proof.** Since the result is purely local, we may assume that

$$
X_l = \partial_{z_l} + \sum_{1 \leq s \leq n} a_{ls}(z) \partial_{z_s}, \quad l = 1, \ldots, n,
$$

...
where \( A := (a_s) \) satisfies \( A(0) = 0 \) and \( \|A(z)\| < 1 \) on \( \Omega \). Applying a unitary change of coordinates, we may assume that \( T_0M = \{y_n = 0\} \). By a \( C^{k+1+\alpha} \) change of coordinates which is tangent to the identity, we may assume that \( M \) is in \( y_n = 0 \). By dilation, we may assume that \( \Omega \) contains \( \mathbb{D}^2_0 \) and that on it we have \( \|A(z)\| < 1/4 \) and \( |A|^{j'+1+\alpha} < 1/C_\ast \). Here \( C_\ast \) will be determined later and

\[
j' := \max \{0, j - 1\} < k.
\]

Finally, by a dilation in the unit disc \( \mathbb{D} \), we achieve \( \|e\|_{C^j(M)} < 1/4 \).

**Step 1. Existence of a solution \( u \) in class \( C^{j'+1+\alpha, j'} \).**

At the origin, \( X_\ell(t) = \partial t \). Let \( \bar{e}_1, \ldots, \bar{e}_{n-1} \) be the standard basis of \( \mathbb{C}^{n-1} \times \{0\} \) and set

\[
P := \mathbb{D}^{n-1}_{1/2n}.
\]

It follows from the assumption made on \( e \cdot X \) that \( \bar{e}_1, \ldots, \bar{e}_{n-1}, e(t, 0) \) are \( \mathbb{C} \)-linearly independent.

Recall that after dilation, \( \partial \mathbb{D} \) is a \( \mathbb{C} \)-linear map \( \Psi \) is a contraction from \( B \) to itself and therefore it has a fixed point \( u \). It follows that \( \Psi(u)(0, t) = \psi(t, 0) \), \( \partial \mathbb{D}(0, t) = \partial \mathbb{D}(t, 0) \), and \( du(0, t)(\partial \mathbb{D}) = (e \cdot X)(t, 0) \). According to Lemma 2.1, \( \Phi \) maps \( B \) to \( B \). Moreover \( P_1 \Phi(u) \) is of class \( \mathcal{C}^{j'} \) in \( t \) and is a polynomial in \( \zeta \).

In particular, \( P_1 \Phi(u) \) and \( \Psi(u) \) are in \( B \). Moreover since \( |A|^{j'+1+\alpha} < 1/C_\ast \) on \( \mathbb{D}^2 \times P \), the map \( \Psi \) is a contraction from \( B \) into itself. Indeed, we have

\[
A(u_2) - A(u_1) = \int_0^1 \left\{ (u_2 - u_1) \cdot (\partial u_2) (u_1 + s(u_2 - u_1)) + (\bar{u}_2 - \bar{u}_1) \cdot \partial \bar{u}_2 u_1 + s(u_2 - u_1) \right\} ds,
\]

\[
|\Phi(u_2) - \Phi(u_1)|^{j'+1+\alpha,j'} \leq C |\partial \mathbb{D}^2 A(u_2) - \partial \mathbb{D}^2 A(u_1)|^{j'+1+\alpha,j'}
\]

\[
\leq C'(1 + |(u_1, u_2)|^{j'+2})^{j'+1+\alpha,j'} |A|^{j'+1+\alpha} |u_2 - u_1|^{j'+1+\alpha,j'}.
\]

Notice that here we need \( A \) to be in \( \mathcal{C}^{j'+1+\alpha} \) instead of \( \mathcal{C}^{j'+\alpha} \). And \( j' + 1 = k \) if \( j' = k - 1 \).

We also have

\[
|P_1 \Phi(u_2) - P_1 \Phi(u_1)|^{j'+1+\alpha,j'} \leq C |\Phi(u_2) - \Phi(u_1)|^{j'+1+\alpha,j'}
\]

Recall that after dilation, \( |A|^{j'+1+\alpha} < 1/C_\ast \). It follows that \( \Phi(u) \) and \( P_1(\Phi(u)) \) have small norms on \( B_1 \). Thus, \( \Psi \) is a contraction map on \( B_1 \) into itself and therefore it has a fixed point \( u \in B_1 \).

**Step 2. Regularity of \( u \) in class \( \mathcal{C}^{j'+1+\alpha,k} \) for finite \( k \).**

This step is the most subtle step of the proof and certainly less classical than the others. We follow the arguments in [16]. This type of arguments has also been used in the Dirichlet
and Neumann problems on planar domains with parameter [3], including the $C^\infty$ case. Here we need to restrict to spaces of finitely derivatives as in [16].

In this step, we assume that $k$ is finite and $j = k = j' + 1$. We have proved that $u \in B_1 \subset C^{k+1+\alpha,k-1}(\mathbb{D}, P)$. In order to prove that $u \in C^{k+1+\alpha,k}$, we first need to show that $\partial^k_t u \in \hat{C}^{1+\alpha,0}(\mathbb{D}, P)$, namely that $u$ is $k$ times differentiable in the $t$-variable, that $t \mapsto \partial^k_t u$ is a continuous map from $P$ to $C^1(\mathbb{D})$ and that $|\partial^k_t u|_{1+\alpha}$ is uniformly bounded. We will then show that $u \in \hat{C}^{2+\alpha,k-1}$, which will be achieved in the next step by shrinking $\mathbb{D}$.

Recall that $u$ satisfies $\Psi(u) = u$ where $\Psi$ is defined by (3.10). Rewrite $u = \Psi(u)$ as

$$ u = h + \Phi(u) - P_1 \Phi(u), $$

where $T = T_{\mathbb{D}}, h$ is holomorphic in $\zeta$ and of class $C^k$ in $t$, and hence $h \in C^{k+1+\alpha,k}$. By differentiating $k - 1$ times the previous equation in the $t$-variable, we obtain

$$ v = TA_1(u)v - P_1 TA_1(u)v + B_{k-1}(u). $$

Here $v := \partial^k_t u \in \hat{C}^{1+\alpha,0}(\mathbb{D}, P)$ and

$$ A_1(u)v := \partial \bar{\zeta} v A(u), \quad \text{when } k = 1; $$

$$ A_1(u)v := \partial \bar{\zeta} v A(u) + \partial \bar{\zeta} u (\partial A(u)v + \partial_{\bar{\zeta}} A(u)v), \quad \text{when } k \geq 2; $$

$$ P_1 TA_1(u)v := (TA_1(u)v)(0,t) + \zeta \partial \zeta (TA_1(u)v)(0,t), $$

$$ E_{k-1}(u) := \sum_{1 \leq l \leq k-2} {k-1 \choose l} \partial \zeta^l \partial_{\bar{\zeta}} A(u), $$

$$ B_{k-1}(u) := \partial^k_t u + T(E_{k-1}(u)) - P_1 T(E_{k-1}(u))(0,t). $$

Notice that $B_{k-1}(u)$ does not depend on $v$ and $B_{k-1}(u) \in \hat{C}^{1+\alpha,1}; E_{k-1} = 0$ when $k = 1, 2$. Also $A_1(u)$ is a differential operator whose coefficients are in $C^\alpha,1$ when $k > 1$ and in $C^{1+\alpha,0}$ when $k = 1$. Fix $t$ in the interior of $P$ and $V \in \mathbb{R}^{2n-2} \setminus \{0\}$. Consider $t' = t + \lambda V \in P$ where $\lambda \in \mathbb{R}^*$. We first need to prove that $\frac{v(t',\cdot) - v(t,\cdot)}{\lambda}$ converges as $\lambda \to 0$. We claim that $|\frac{v(t',\cdot) - v(t,\cdot)}{\lambda}|_{1+\alpha}$ is bounded for $\lambda$ in a neighborhood of 0. Let

$$ I(t', t) := TA_1(u(\cdot, t'))v(\cdot, t') - TA_1(u(\cdot, t))v(\cdot, t). $$

Let us consider the case $k = 1$ first. In this case $v = u$. We decompose

$$ I(t', t) = T \left\{ (\partial \bar{\zeta} u(\cdot, t') - \partial \bar{\zeta} u(\cdot, t)) A(u(\cdot, t')) + \partial \bar{\zeta} u(\cdot, t) (A(u(\cdot, t')) - A(u(\cdot, t))) \right\}. $$

Using $A(u(\cdot, t')) - A(u(\cdot, t)) = \int_{s=0}^{1} \frac{d}{ds} \{ A(su(\cdot, t') + (1-s)u(\cdot, t)) \} ds$, we obtain

$$ |(A(u(\cdot, t')) - A(u(\cdot, t)))|_\alpha \leq C |A|_{1+\alpha} |u(\cdot, t') - u(\cdot, t)|_\alpha. $$

Thus

$$ |\lambda^{-1} I(t', t)|_{1+\alpha} \leq c |A|_{1+\alpha} |\lambda^{-1} (u(\cdot, t') - u(\cdot, t))|_{1+\alpha}, $$
for some positive constant $c$. Here, we have used the fact that $|u(\cdot, t)|_{1+\alpha}$ is bounded in $t$, due to $u \in C^{1+\alpha,0}$. From the definition of $P_1TA_1(u)v$, we obtain from (3.13)
\[
|\lambda^{-1}\{P_1TA_1(u)u(\cdot, t) - P_1TA_1(u)u(\cdot, t)\}|_{1+\alpha} \leq c' |\lambda^{-1}I(t', t)|_{1+\alpha}.
\]
We also have $|\lambda^{-1}\{B_1(\cdot, t') - B_1(\cdot, t)\}|_{1+\alpha} \leq C|h|_{2+\alpha}$. Since $|A|_{1+\alpha}$ can be chosen arbitrarily small, it follows that $\frac{|u(\cdot, t') - u(\cdot, t)|}{\lambda}$ is bounded for $\lambda$ in a neighborhood of 0. Thus, there exist a sequence $\lambda_\nu \to 0$ and a map $w(\cdot, t)$ of class $C^{1+\alpha}$ such that $|w(\cdot, t)|_{1+\alpha}$ is uniformly bounded and such that for $t_\nu := t + \lambda_\nu V$, we have $\frac{|u(t, t_\nu) - u(t, t)|}{\lambda_\nu} \to 0$, $|\partial_x u(t, t_\nu) - \partial_x u(t, t)| \to 0$ and $|\partial_x u(t, t_\nu) - \partial_x u(t, t)| \to 0$ (see 7.1e. in [16]).

Since $T: L^\infty(\mathbb{D}) \to L^\infty(\mathbb{D})$ is bounded, it follows that $w(\cdot, t)$ satisfies the following equation
\[
(3.14) \quad w = (I - P_1)T \left\{ \frac{\partial_x wA(u) + \partial_x u(\partial_x A(u)w + \partial_x A(u)\bar{w})}{\partial_x w} \right\} + \partial_x h.
\]
Now, if $w'(\cdot, t) \in C^{1+\alpha}$ is another solution of (3.14) then
\[
|w(\cdot, t) - w'(\cdot, t)|_{1+\alpha} \leq C|A|_{1+\alpha}(|u|_{1,0} + |u|_{1+\alpha,0})|w(\cdot, t) - w'(\cdot, t)|_{1+\alpha}.
\]
Recall that $|u|_{1+\alpha,1} \leq 1$. Thus $w = w'$. Therefore the solution $w$ is unique, which proves that $\frac{u(t, t_\nu) - u(t, t)}{\lambda_\nu}$ converges to $w(\cdot, t) = \partial_x u(\cdot, t)$ in $|.|_1$. Next, we want to show that the map $t \mapsto w(\cdot, t)$ is continuous from $P$ into $C^1$. Let $t_\nu$ be a sequence in $P$ converging to $t$. Since $w(\cdot, t_\nu)$ is a sequence of bounded maps in $C^{1+\alpha}(\mathbb{D})$, it admits a subsequence, still denoted by $w(\cdot, t_\nu)$ that converges in $|.|_{c^1}$ to a map $\tilde{w} \in C^{1+\alpha}$. It follows that $w$ satisfies the equation (3.14) in which $w$ is replaced by $\tilde{w}$. By the uniqueness of the solution of (3.14), we obtain $w(\cdot, t_\nu) \to \tilde{w}(\cdot, t)$ as $|t_\nu - t| \to 0$. This proves that $w = \partial_x u \in C^{1+\alpha,0}(\mathbb{D}, P)$.

Consider now the case $k \geq 2$, which produces some extra terms. The above arguments can be repeated easily. Now $\partial_x^{k-1} u$ is different from $u$. Set $w_1 := \partial_x^{k-1} u \partial_x A(u)$, $w_2 := \partial_x^{k-1} u \partial_x A(u)$. We decompose $I(t', t)$ in the following way
\[
I(t', t) = T \left\{ (\partial_x v(\cdot, t') - \partial_x v(\cdot, t))A(u(\cdot, t')) + \partial_x v(\cdot, t')(A(u(\cdot, t')) - A(u(\cdot, t))) \right\}
+ T \left\{ (w_1(\cdot, t') - w_1(\cdot, t))v(\cdot, t') + (v(\cdot, t') - v(\cdot, t))w_1(\cdot, t') \right\}
+ T \left\{ (w_2(\cdot, t') - w_2(\cdot, t))\bar{v}(\cdot, t') + (\bar{v}(\cdot, t') - \bar{v}(\cdot, t))w_2(\cdot, t') \right\}.
\]
Since $k \geq 2$, we have $|w_1(\cdot, t')|_\alpha \leq C|A|_{2+\alpha}|u|_{1+\alpha,0}$. Recall that $|u|_{2+\alpha,1} \leq 1$. We can get $|w_1(\cdot, t') - w_1(\cdot, t)|_\alpha \leq C|A|_{2+\alpha}|u(\cdot, t') - u(\cdot, t)|_{1+\alpha} \leq C|A|_{2+\alpha}||u||_{2+\alpha,1}$. We obtain
\[
(3.15) \quad |\lambda^{-1}I(t', t)|_{1+\alpha} \leq C|A|_{2+\alpha} |\lambda^{-1}(v(\cdot, t') - v(\cdot, t))|_{1+\alpha} + C|u|_{2+\alpha,1}.
\]
Again, from the definition of $P_1TA_1(u)v$, we obtain from (3.15)
\[
|\lambda^{-1}\{P_1TA_1(u)v(\cdot, t') - P_1TA_1(u)v(\cdot, t)\}|_{1+\alpha} \leq c' |\lambda^{-1}I(t', t)|_{1+\alpha}.
\]
We also have $|\lambda^{-1}\{B_{k-1}(\cdot, t') - B_{k-1}(\cdot, t)\}|_{1+\alpha} \leq C(|h|_{k+1+\alpha,k} + |u|_{k+\alpha,k-1})$. Since $|A|_{2+\alpha}$ can be chosen arbitrarily small, it follows that as before there exist a sequence $\lambda_\nu \to 0$ and a map $w(\cdot, t)$ of class $C^{1+\alpha}$ such that $|w(\cdot, t)|_{1+\alpha}$ is uniformly bounded and such that
for \( t_\nu := t + \lambda_\nu V_\nu \), the sequence \( \frac{v(\nu,t) - v(\cdot,t)}{\lambda_\nu} - w(\cdot,t) \), together its first order derivatives, converges to zero as \( \lambda_\nu \to 0 \). Also

\[
\begin{align*}
\frac{\partial}{\partial t} w A(u) + \frac{\partial}{\partial t} w A_u u A(u) \frac{v}{\partial t} u A_A(u) w \\
+ (I - P_1) T \left\{ \partial_t \left( u \partial_t A(u) + \partial_t (u \partial_t A(u)) v + \partial_t u \partial_t A(u) w \right) \right\}
\end{align*}
\]

This equation is similar to (3.14) as \( |A(u)|_\alpha \leq C|A|_\alpha \) and

\[
\left| \partial_\zeta u \partial_n A(u) \right|_\alpha \leq C|u|_{1+\alpha,0} |A|_{1+\alpha} |u|_1^\alpha \leq C|A|_{1+\alpha}
\]

can be chosen arbitrary small. By repeating the rest of arguments from the case \( k = 1 \), we can verify that \( \partial_\nu^k u \in \mathcal{C}^{1+\alpha,0}(\mathbb{D}, P) \).

**Step 3. Regularity of \( u \) in \( \mathcal{C}^{k+1+\alpha,k} \) for finite \( k \) or in \( \mathcal{C}^{\infty,j} \).**

Recall by Step 2 that we need to show that \( u \in \mathcal{C}^{2+\alpha,k-1} \) when \( j = k \) is finite. We have also proved that \( u \in \mathcal{C}^{j+1+\alpha,j}(\mathbb{D}, P) \cap \mathcal{C}^{1+\alpha,k}(\mathbb{D}, P) \). We will only able to improve the regularity in interior of \( \mathbb{D} \). To achieve Step 3 and to demonstrate the differences between Steps 1 and 2, we will show a stronger result. Assume that the almost complex structure is of class \( \mathcal{C}^{k+\alpha} \) with \( k > j \) (this includes the case \( j = k \) which is treated in Step 2 for finite \( k \)). Assume that for all \( l \leq j \), \( \partial_t^l u \) is continuous on \( \mathbb{D} \times P \) and that distributional derivatives \( \partial_\zeta \partial_t^l w(\cdot,t) \) have bounded \( \mathcal{L}^p(\mathbb{D}) \) norms on \( \mathbb{D} \) for \( p > 2 \). Moreover, suppose that \( u(\cdot,t) \) is \( J \)-holomorphic on \( \mathbb{D} \). Then \( u \in \mathcal{C}^{k+1+\beta,j}(\mathbb{D}_r, P) \) for \( r < 1 \) and \( \beta = \min(\alpha, 1-2/p) \).

The proof is achieved by induction on the order of the derivative in the \( \zeta \)-variable.

According to (3.9), the first-order derivatives of \( \partial_\zeta^l u(\cdot,t) \) have bounded \( \mathcal{L}^p(\mathbb{D}) \) norms on \( P \). By Morrey’s inequalities, \( u \in \mathcal{C}^{\beta,j}(\mathbb{D}_r, P) \) for any \( r < 1 \) (see Lemma 7.16 and Theorem 7.17 in [8], pp. 162-163). Fix \( \zeta_0 \in \mathbb{D} \) and set \( A_0 := A(u(\zeta_0, t)) \), \( u = \bar{u} + \bar{u} A_0 \) and \( u_*(\zeta, t) := \bar{u}(\zeta, t) \) with \( \zeta_* := \zeta_0 + \mu \zeta \). Here \( 0 < \mu < \frac{1}{2}(1 - |\zeta_0|) \) will be determined later.

According to (3.9), we get on \( \mathbb{D} \)

\[
\begin{align}
\partial_\zeta u_* &= \bar{\zeta} w A_*(\zeta, t), \quad A_*(0, t) = 0, \\
A_*(\zeta, t) &= [A(u(\zeta_0 + \mu \zeta, t)) - A_0][I - \bar{A}_0 A]^{-1}.
\end{align}
\]

We emphasize that \( A_*(\zeta, t) \) is considered as a matrix functions in \( \zeta \) and \( t \), but not in \( u_* \).

Let \( \chi \) be a smooth real function with compact support in \( \mathbb{D}_{1/4} \). Let \( v := \chi u_* \). Multiply (3.16) by \( \chi \) and rewrite it as

\[
\partial_\zeta v - \bar{\zeta} v A_*(\zeta, t) = \partial_\zeta \chi u_* - \bar{\zeta} \chi u_* A_*(\zeta, t).
\]

Let \( \tilde{\chi} \) be a smooth real function with compact support in \( \mathbb{D} \) such that \( \tilde{\chi} = 1 \) on \( \mathbb{D}_{1/4} \) and \( \tilde{\chi} \leq 5 \). Replacing \( A_* \) by \( \tilde{\chi} A_* \), we may assume that \( A_*(\cdot, t) \) has compact support in \( \mathbb{D} \). Using (3.17), we get for \( \zeta, \zeta' \in \mathbb{D} \),

\[
\begin{align*}
|A_*(\zeta, t)| \leq C|A(u(\cdot, t))|_\beta \mu^\beta, \\
|A_*(\zeta', t) - A_*(\zeta, t)| \leq C|A(u(\cdot, t))|_\beta \mu^\beta |\zeta' - \zeta|\beta.
\end{align*}
\]

Therefore

\[
\|A_*\|_{\beta,0} \leq C|A \circ u|_{\beta,0} \mu^\beta < \epsilon_\beta.
\]
Here $\epsilon_\beta$ is the constant in Lemma 2.2 and $\mu$ is sufficiently small. Apply $T = T_\mathbb{D}$ to (3.18). Since $v$ has compact support we have

$$v - T(\partial \zeta v A_s) = T(\partial \zeta u_* - \partial \zeta u_A) =: w. \tag{3.19}$$

The transpose of the solution $v$ is equal to $(1 - TA_s^{T})^{-1} w^{t}$. Since $u_*$ is in $\dot{C}^{1+\beta}((\mathbb{D}, P)$, then $A_*$ and $w$ are in $\dot{C}^{1+\beta}(\mathbb{D}, P)$. By Lemma 2.2, $v$ is in $\dot{C}^{1+\beta}(\mathbb{D}, P)$. Hence $u \in \dot{C}^{1+\beta,j}(\mathbb{D}, P)$ for any $0 < r < 1$. Assume that we have achieved $u \in \dot{C}^{1+\beta,j}(\mathbb{D}, P)$ for any $0 < r < 1$ and $l < k + 1 - j$. Since $A_*$ has compact support in $\mathbb{D}$, then $A_* \in \dot{C}^{1+\beta,k}(\mathbb{D}, P)$. By $|A_*|_{\alpha,0} < \epsilon_\alpha$, (3.19) and Lemma 2.2, we get $v \in \dot{C}^{1+\beta,j}(\mathbb{D}, P)$. This shows that $u \in \dot{C}^{k+1+\beta,j}(\mathbb{D}, P)$ for any $r < 1$.

**Step 4. Construction of $R$.**

We assume that $\Omega^+$ and $M$ are subsets defined by $y_n > 0$ and $y_n = 0$, respectively. Let $e(t, 0) = (a, b + ib')$. Since $e(t, 0) \cdot \partial \zeta$ is not tangent to $M$, then $b' + ib'' \neq 0$. Recall that $u = \Psi(u)$. By (3.10), $D(t) \cap M$ is defined by

$$b'\xi + b''\eta = F(\xi, \eta, t), \quad F(\xi, \eta, t) = \text{Im}\{P_1 \Phi(u(\xi + i\eta, t)) - P_1 \Phi(u(\xi + i\eta, t))\}. \tag{3.20}$$

Without loss of generality, we may assume that $b' \geq |b''|$. We already know that $F \in \mathcal{C}^{k+1+\alpha,j}(\mathbb{D}, P)$. We may also achieve $|\partial_\eta F| < b'/2$ by assuming $|A|_{j+\alpha} < 1/C_*$. By the implicit function theorem, (3.20) has a solution $\eta = h(\xi, t)$ for $|\xi| < r/c$ and $t \in P$. Now

$$(\partial_\zeta h, \partial_\zeta h) = (b' - \partial_\eta F(\xi, \eta, t))^{-1}(\partial_\zeta F - b'', \partial_\zeta F)$$

implies that $\partial_\zeta h \in \mathcal{C}^{k+1+\alpha - l}$ for all $l \leq j$. On $\mathbb{D}_{r/c} \times P$, define

$$R(\zeta, t) := u(\xi + i(\eta + h(\xi, t)), t).$$

It follows that $R(\zeta, t)$ sends $\mathbb{D}_{r/c}$ into $D^+(t)$. Replace $R(\zeta, t)$ by $R(\zeta/c, t)$. The remaining assertions can be verified easily.

We point out that Proposition 3.7 fails if the almost complex structure is merely Hölderian. Indeed, in Ivashkovich-Pinchuk-Rosay [13], an almost complex structure of class $\mathcal{C}^{1/2}$ is defined on $\Omega = \mathbb{D}_2 \times \mathbb{D}_{1/10} \subset \mathbb{R}^4$ together with a family of pseudoholomorphic discs $u(., t) : \mathbb{D} \to \Omega$ of class $\mathcal{C}^{1+1/2}$ such that $u(\zeta, 0) = (2\zeta, 0)$, and such that for $t \neq 0$, $u(0, t) = (0, t)$ and $|\partial_\zeta u(0, t)| \leq A$ for some $A < 2$. In particular, the map $t \mapsto u(., t) \in \mathcal{C}^1$ is not continuous at 0, and so $u \notin \mathcal{C}^{1+1/2,0}$.

It is well-known that via the Fourier transform, the boundedness of derivatives of a function on all lines parallel to coordinates axes yields some smoothness of the function in all variables (see Rudin [20], p. 203). To limit the loss of derivatives, we will use the Fourier transform only on curves. This requires us to bound derivatives of a function on a larger family of curves.

Let $\gamma$ be a curve of class $\mathcal{C}^k$ in $\mathbb{R}^n$ and let $f$ be a function of class $\mathcal{C}^k$ on $\mathbb{R}^n$. We have

$$\partial_t^k f(\gamma(t)) = ((\gamma'(t) \cdot \partial)^k f)(\gamma(t)) + \sum_{1 \leq |I| < k} Q_{k,I}(\partial_t^{(k+1-|I|)} \gamma)(\partial^I f)(\gamma(t)), \tag{3.21}$$

where $Q_{k,I}$ are polynomials, $\partial^{(k)}$ denotes derivatives of order $k$, and

$$v \cdot \partial = v_1 \partial_{x_1} + \cdots + v_n \partial_{x_n}.$$
Let \( \partial \) be a positive integer and let \( \epsilon > 0 \).

(i) There exist \( N \) vectors \( v_j = (1, v_j') \in \mathbb{R}^n \) such that \( |v_j'| < \epsilon \) and
\[
\partial^I = c_{I,1}(v_1 \cdot \partial)^k + \cdots + c_{I,N}(v_N \cdot \partial)^k, \quad |I| = k.
\]

(ii) If \( v_1, \ldots, v_N \) satisfy (3.22), there exists \( \delta > 0 \) such that if \( |u - v| < \delta \), then
\[
\partial^I = Q_{I,1}(u)(u_1 \cdot \partial)^k + \cdots + Q_{I,N}(u)(u_N \cdot \partial)^k, \quad |I| = k.
\]

Here \( Q_{I,j} \) are rational functions with \( Q_{I,j}(v) = c_{I,j} \). Moreover \( N \) depends only on \( k, n \).

**Proof.** (i). Equivalently, we need to verify (3.22)-(3.23) when \( \partial \) is replaced by \( \xi \in \mathbb{R}^n \).
It holds for \( n = 1 \). Assume that it holds when \( n \) is replaced by \( n - 1 \). For \( \xi_n^k \), we take distinct non-zero constants \( \lambda_1, \ldots, \lambda_k \). Then \( \xi_n^k \) is in the linear span of \( \xi_1^k, (\xi_1 + \lambda_1 \xi_n)^k, \ldots, (\xi_1 + \lambda_k \xi_n)^k \). Let \( \xi_n^k P(\xi_1, \ldots, \xi_{n-1}) \) be a monomial of degree \( k > j \). Then by induction assumption
\[
\xi_n^k P(\xi_1, \ldots, \xi_{n-1}) = \xi_n^k [c_1(v_1 \cdot \xi)^{k-j} + \cdots + c_j(v_j \cdot \xi)^{k-j}],
\]
where \( v_j = (1, v_j'', 0) \) with \( |v_j''| < \epsilon/2 \). Then \( \xi_n^k(v_l \cdot \xi)^{k-i} \) are in the linear span of \( (v_1 \cdot \xi)^k \), \( (v_l \cdot \xi + \lambda_1 \xi_n)^k, \ldots, (v_l \cdot \xi + \lambda_k \xi_n)^k \). Note that \( \lambda_j \)'s can be arbitrarily small. Thus, (i) is verified.

(ii). For \( |I| = k \) we have the following expansions
\[
\xi^I = \sum_{1 \leq j \leq N} c_{I,j}(v_j \cdot \xi)^k, \quad \xi^I = \sum_{1 \leq j \leq N} c_{I,j}(u_j \cdot \xi)^k + \sum_{|I|=k} \tilde{Q}_{I,J'}(v - u)\xi^I.
\]
Clearly, \( \tilde{Q}_{I,J'}(0) = 0 \). Moving the last sum to the left-hand side and inverting \( 1 - \tilde{Q}_{I,J'} \) yields (3.23). \( \square \)

It is elementary that the smoothness of a function on all lines does not yield the smoothness of the function. However, if the norms of derivatives on lines are uniformly bounded, we can achieve the smoothness of the function. For the proof of Theorem 1.1, we need to use derivatives of functions on families of curves. This is the content of the following proposition (see [23] for a similar statement). Set \( t' = (t_2, \ldots, t_n) \) and \( t = (t_1, t') \).

**Proposition 3.9.** Let \( k, N \) be positive integers. For \( j = 1, \ldots, N \), let \( R_j \) be \( C^1 \) diffeomorphisms from \( \Omega_j \subset \mathbb{R}^n \) onto an open subset \( \Omega \subset \mathbb{R}^n \). Assume that \( R_j(\cdot, t') \in C^k \) and that \( R_j(0) = 0 \). Suppose that at \( 0 \in \Omega \)
\[
(3.24) \quad \partial^I = \sum_{1 \leq j \leq N} c_{I,j}(\partial_{t_1} R_j(0) \cdot \partial)^{|I|}, \quad 1 \leq |I| \leq k.
\]

Let \( f \in C^0(\Omega) \). Then the following hold:

(i) Let \( f \) be of class \( C^k \) near \( 0 \in \Omega \). Then for \( x = R_j(t') \) near \( 0 \)
\[
(3.25) \quad \partial^I f(x) = \sum_{1 \leq i \leq m} \sum_{1 \leq j \leq N} Q_{I,j}\left( \partial_{t_1}^{(m-i+1)} R_1(t'), \ldots, \partial_{t_N}^{(m-i+1)} R_N(t') \right) \partial_{t_i}^I f(R_j(t')),
\]
where \( Q_{1,j} \) are rational functions without pole at \( (\partial_{t_{1}}^{(m-l+1)}R_{1}(0), \ldots, \partial_{t_{N}}^{(m-l+1)}R_{N}(0)) \), and \( 1 \leq m = |I| \leq k \). Moreover (3.25) holds on a domain \( \omega \) if \( f \in C^{k}(\omega) \) and \( 0 \in \partial \omega \subset B^{r}_{k} \) where \( \epsilon \) is sufficiently small.

(ii) Suppose that \( R_{j} \) are affine, i.e. \( R_{j}(t) - R_{j}(y) = R_{j}(t-y) \) whenever they are defined. Suppose that the \( L^{p}_{\omega} \) norms of one-dimensional distributions \( \partial_{t_{i}}^{m}(f \circ R_{j})(\cdot,t') \) are bounded in \( t' \) for all \( m \leq k \). Then near 0, \( \partial^l f \) are Lipschitz functions for all \( |I| < k \).

(iii) Let \( R_{j} \) be of class \( C^{k+1} \) near 0 \( \in \mathbb{R}^{n} \) and let \( n < p < \infty \). Suppose that the \( L^{p}_{\omega} \) norms of one-dimensional distributions \( \partial_{t_{i}}^{m}(f \circ R_{j})(\cdot,t') \) are bounded in \( t' \) for all \( m \leq k \). Then near 0, \( f \) is of class \( C^{k-\frac{m}{p}} \).

Proof. (i) follows from (3.21) and (3.23), by hypothesis (3.24).

(ii). Applying dilation and replacing \( f \) by \( \chi f \), we may assume that \( f \) has compact support in \( \Delta^{n} \). Set \( \chi_{\epsilon}(x) := \epsilon^{-n}(x^{-1}x) \) for a smooth function \( \chi \) with support in \( \Delta^{n} \) and \( \int \chi \, dx = 1 \). Set \( f_{\epsilon}(x) := \int f(y)\chi_{\epsilon}(x - y) \, dy \) and \( f_{\epsilon,j} := f_{\epsilon} \circ R_{j} \). Changing variables via \( R_{j} \), we get

\[
f_{\epsilon,j}(t) = \int f(R_{j}(t) - R_{j}(y))\chi_{\epsilon}(R_{j}(y)) \, dy.
\]

Using \( R_{j}(t) - R_{j}(y) = R_{j}(t-y) \), we get \( |f_{\epsilon,j}(\cdot,t')|_{k} < C \) for \( C \) independent of \( \epsilon \) and \( t' \). In (3.25), we substitute \( f_{\epsilon} \) for \( f \). Therefore, \( \partial^{l} f_{\epsilon} \) are bounded near 0. We can find a sequence \( f_{\epsilon,j} \) such that as \( \epsilon \) tends to 0, \( \partial^{l} f_{\epsilon} \) converges uniformly for \( |I| < k \), and the Lipschitz norms of \( \partial^{l} f_{\epsilon,j} \) are bounded. Since \( f_{\epsilon} \) converges uniformly to \( f \) as \( \epsilon \to 0^{+} \) then \( \partial^{k-1} f \in Lip_{loc} \).

(iii). For such a function \( f \), we define a distribution \( T_{j}f \) by

\[
T_{j}f(\phi) := (-1)^{k} \int_{\mathbb{R}^{n}} f \circ R_{j}(t)\partial_{t_{i}}^{k}\phi(R_{j}(t)) \, dt,
\]

where \( \phi \) is a test function supported in \( \Delta^{n} \) with \( \epsilon \) small. It is clear that defined near 0, \( T_{j}f \) is a distribution of order \( (\leq k) \). Integrating by parts in the \( t_{1} \)-variable yields

\[
|T_{j}f(\phi)| \leq C \int_{\mathbb{R}^{n-1}} \|\partial_{t_{i}}^{k}[f \circ R_{j}](\cdot,t')\|_{L^{p}_{\omega}} \|\phi \circ R_{j}(\cdot,t')\|_{L^{q}_{\omega}} \, dt'
\]

\[
\leq C_{1} \int_{\mathbb{R}^{n-1}} \|\phi \circ R_{j}(\cdot,t')\|_{L^{q}_{\omega}} \, dt' \leq C_{2} \|\phi \circ R_{j}\|_{L^{q}} \leq C_{3} \|\phi\|_{L^{q}}.
\]

Here the first and the second last inequalities are obtained from the Hölder inequality and from \( \text{supp} \phi \subset \Delta^{n} \). Hence near 0, \( T_{j}f \in L^{p} \) for \( p > 1 \). Next we find a differential operator \( P_{j,k}(\partial) \) of order \( k \) such that \( P_{j,k}(\partial)f = T_{j}f \). In order to find it, we use a smooth function \( g \) to obtain

\[
T_{j}g(\phi) = \int \partial_{t_{i}}^{k}[g \circ R_{j}(t)]\phi(R_{j}(t)) \, dt = \int (\phi \partial_{j,k}(\partial)g) \circ R_{j}(t) \, dt
\]

\[
= \int |\det((R_{j}^{-1})\partial)\partial_{j,k}(\partial)g| \phi \, dx =: (P_{j,k}(\partial)g)(\phi).
\]

Since \( R_{j} \in C^{k+1} \), it is easy to see that

\[
P_{j,k}(\partial) = \det((R_{j}^{-1})\partial)\partial_{j,k}(\partial) = \sum_{|I| \leq k} a_{j,k,I}\partial^{I}, \quad a_{j,k,I} \in C^{1}[t].
\]
The last assertion implies that $P_{j,k}(\partial) \circ \partial f$ has order $k$. The definition of $T_j f$ and the identity $P_{j,k}(\partial)g = T_j g$ imply that as distributions defined near 0, we have $P_{j,k}(\partial) f = T_j f$.

Note that

$$\sum_{|I|=k} a_{j,k,I}(x) \partial_x = \sum_{|I|=k} C_I \left( \frac{1}{\partial_x} \right)^I (R_j^{-1}(x)) \frac{\partial x}{\partial x} \frac{\partial_x}{\partial_x}, \quad C_I \neq 0.$$ 

Here $t^I = R_j^{-1}(x)$. Combining with (3.24), we get for $g \in C^k$ and $1 \leq |I| \leq k$,

$$\partial^I g = \sum_{1 \leq i \leq m} \sum_{1 \leq j \leq N} b_{l,j,i} P_{j,l}(\partial) g, \quad b_{l,j,i} \in C^l.$$ 

The last assertion, combined with ord $P_{j,l}(\partial) \leq l$, $a_{j,k,l} \in C^{(l)}$ and $P_{j,l}(\partial) f \in L^p$, implies that near 0, $\partial^I f$ are in $L^p$ for $1 \leq |I| \leq k$. Therefore, $f \in W^{k,p}_\text{loc}$, and $f \in C^{k-\frac{n}{2}}$ by a Sobolev embedding theorem (see [11], p. 123). \[ \square \]

4. CAUCHY-GREEN OPERATOR ON DOMAINS WITH PARAMETER

The following result is certainly classical; see [24], Section 8.1 (pp. 56-61). For the convenience of the reader, we present details for a parameter version. Recall that $P$ is the closure of a bounded open set in a Euclidean space and that two points $a, b$ in the interior of $P$ can be connected by a smooth curve in the interior of length at most $C|b-a|$.

**Lemma 4.1.** Let $\tau$ be a complex-valued function on $\mathbb{D}^+ \times P$ of class $C^{k+1+\alpha,0}(\mathbb{D}^+, P)$. Suppose that for $z, z' \in \mathbb{D}^+$ and $t \in P$,

$$\tau(z', t) - \tau(z, t) | \geq |z' - z|/C.$$

(i) Let $f$ be a continuous function on $[-1, 1] \times P$. For $z \in \mathbb{D}^+$, define

$$C_0 f(z, t) := \frac{1}{2\pi i} \int_{-1}^{1} \frac{f(s, t)}{\tau(s, t) - \tau(z, t)} \, ds.$$ 

Then $|\partial^k C_0 f(z, t)| \leq C_k |f|_{L^\infty}/|\text{Im } z|^{k+1}$, where $C_k$ depends only on $|\tau|_{k, 0}$.

(ii) Let $f$ be a function of class $C^{k+\alpha,0}([-1, 1], P)$. Then $C_0 f$ extends continuously to $(\mathbb{D}^+ \cup (-1, 1)) \times P$. Moreover, $C_0 f \in C^{k+\alpha,0}(\mathbb{D}^+, P)$ for any $r < 1$ and satisfies $|C_0 f|_{k+\alpha,0} \leq C|f|_{k+\alpha,0}$.

(iii) Let $f$ be a function of class $C^{k+\alpha,0}(\mathbb{D}^+, P)$. For $z \in \mathbb{D}^+$, define

$$S_0 f(z, t) := -\frac{1}{2\pi} \lim_{\epsilon \to 0} \int_{|\xi| \in \mathbb{D}^+ : |\tau(\xi, t) - \tau(z, t)| > \epsilon} \frac{f(\xi, t)}{\tau(\xi, t) - \tau(z, t)} \, d\xi d\eta,$$

$$T_0 f(z, t) := -\frac{1}{2\pi} \int_{\mathbb{D}^+} \frac{f(\xi, t)}{\tau(\xi, t) - \tau(z, t)} \, d\xi d\eta.$$ 

Then $S_0 f \in C^{k+\alpha,0}(\mathbb{D}^r, P)$ and $T_0 f \in C^{k+1+\alpha,0}(\mathbb{D}^r, P)$ for any $r < 1$ with $|S_0 f|_{k+\alpha,0} + |T_0 f|_{k+1+\alpha,0} \leq C|f|_{k+\alpha,0}$.

**Proof.** (i). Note that (4.1) implies that $|\tau(z, t) - \tau(s, t)| \geq \text{Im } z/C$ for $-1 \leq s \leq 1$ and $z \in \mathbb{D}^+$. The proof is straightforward by taking derivatives in $z, \overline{z}$ directly onto the kernel.
(ii). Let $z = x + iy$. Let $\chi$ be a smooth function with compact support in $(-1, 1)$. Replacing $f(x, t)$ with $\chi(x)f(x, t)/\partial_x \tau(x, t)$, it suffices to get the norm estimate on $\mathbb{D}_r^+ \times P$ for

\begin{equation}
C_0 f(z, t) = \frac{1}{2\pi i} \int_{\partial \mathbb{D}^+} \frac{f(\zeta, t)}{\tau(\zeta, t) - \tau(z)} d\tau(\zeta, t)
= \frac{1}{2\pi i} \int_{\partial \mathbb{D}^+} \frac{f(\zeta, t) - f(x, t)}{\tau(\zeta, t) - \tau(z)} d\tau(\zeta, t) + \epsilon f(x, t).
\end{equation}

Here the differentiation and integration are in $\zeta$, and $\epsilon = 1$ if $\tau(\cdot, t)$ preserves the orientation of $\mathbb{D}^+$; otherwise $\epsilon = -1$. From (4.1) and $\tau \in C^{1,0}(\mathbb{D}^+, P)$, we know that $\epsilon$ is independent of $t$. Let $C_1 f$ denote the second integral in (4.2). Let $\partial^j$ denote a $j$-th derivative in $x, y$.

In what follows, the norms $| \cdot |_{j+a,0}$ for $f, \tau$ are on $\mathbb{D}^+$, and norms $| \cdot |_{j+a,0}$ for $C_0 f$ are on $\mathbb{D}_r^+$ with $r < 1$. These norms will be denoted by the same notation $| \cdot |_{j+a}$. Since $t$ is fixed, we suppress it in all expressions. All constants are independent of $t$.

That $C_0 f$ extends continuously to $\overline{\mathbb{D}}^+ \times P$ follows from the continuity of $f$ and

$$
\frac{|f(s) - f(x)|}{|\tau(s) - \tau(z)|} \leq C |f|_{a} |x - s|^{a-1}.
$$

Take (4.2) as the definition of $C_0$. Differentiating it gives

\begin{equation}
\partial C_0 f(z) = \frac{\partial \tau(z)}{2\pi i} \int_{\partial \mathbb{D}^+} \frac{f(\zeta) - f(x)}{\tau(\zeta) - \tau(z)^2} d\tau(\zeta).
\end{equation}

Using $|\tau(s) - \tau(z)| \geq (|s - x| + |y|)/C$, we get

$$
|\partial C_0 f(z)| \leq |\tau|_1 \int_{\partial \mathbb{D}^+} \frac{|f|_{a,0}|s - x|^a}{|y|^2 + |s - x|^2} ds \leq C |f|_{a,0} |y|^{a-1}.
$$

By a Hardy-Littlewood type lemma, we obtain $|C_0 f|_{a,0} \leq C |f|_{a,0}$. For higher derivatives of $C_0 f$, we differentiate (4.2) in the $z$-variable and transport derivatives to $f$ via integration by parts. We get for $|I| = k$

\begin{equation}
\partial^I C_0 f(z) = \sum_{|K| = |I|} \partial^K \tau(z) \cdot \partial^K \tau(z) \int_{\partial \mathbb{D}^+} \frac{f_{IK}(\zeta)}{\tau(\zeta) - \tau(z)} d\tau(\zeta).
\end{equation}

Here $f_{IK}(s)$ are polynomials in $(\partial_s \tau(s))^{-1}, \partial_s^l f(s), \partial_s^{l+1} \tau(s)$ with $l \leq k$. As before, we have the continuity of

$$
\frac{1}{2\pi i} \int_{\partial \mathbb{D}^+} \frac{f_{IK}(\zeta)}{\tau(\zeta) - \tau(z)} d\tau(\zeta) = \frac{1}{2\pi i} \int_{\partial \mathbb{D}^+} \frac{f_{IK}(\zeta) - f_{IK}(x)}{\tau(\zeta) - \tau(z)} d\tau(\zeta) + \epsilon f_{IK}(x).
$$

By differentiating the integral in (4.4) one more time, we get a formula analogous to (4.3).

As in case $k = 0$, we can verify that the $C^a$ norms of $\partial^k C_0 f(\cdot, t)$ on $\mathbb{D}_r^+$ are bounded.

(iii). We first show that $S_0 f \in C^{a,0}(\overline{\mathbb{D}}^+, P)$. Let $-2id\xi \wedge d\eta = A(\zeta, t) d\tau(\zeta, t) \wedge d\overline{\tau}(\zeta, t)$. Let $\chi$ be a smooth function with compact support in $\mathbb{D}_r^+ \cup (-r', r')$, where $0 < r < r' < 1$. By replacing $f(\zeta, t)$ by $\chi(\zeta)f(\zeta, t)A(\zeta, t)$, we may reduce to the case where $f(\cdot, t)$ is supported in $\mathbb{D}_r^+$ with $r < r' < 1$. We may also replace the domain of integration by
a smooth domain \( D \) with \( \mathbb{D}_r^+ \subset \overline{D} \subset \mathbb{D}_r^e \). Again, we suppress the parameter \( t \) in all expressions and write

\[
S_0 f(z) = \frac{1}{2\pi i} \int_D \frac{f(\zeta) - f(z)}{(\tau(\zeta) - \tau(z))^2} d\tau(\zeta) - \frac{f(z)}{2\pi i} \int_{\partial D} \frac{d\tau(\zeta)}{\tau(\zeta) - \tau(z)}.
\]

On \( \partial D \), write \( d\tau(\zeta) = a_0(\zeta) d\tau(\zeta) \). By \((ii)\), we know that the last integral in (4.5) is in \( C^{t,0}(\mathbb{D}^+_r, P) \). Denote the first integral in (4.5) by \( \tilde{g}(z)/(2\pi i) \). That \( \tilde{g} \) extends continuously follows from the continuity of \( f \) and \(|f(\zeta) - f(z)|/|\tau(\zeta) - \tau(z)|^2 \leq C|\zeta - z|^\alpha - 2 \). Write

\[
\tilde{g}(z_2) - \tilde{g}(z_1) = \int_{D} \frac{(f(z_1) - f(z_2)) d\tau(\zeta) \wedge d\overline{\tau(\zeta)}}{(\tau(\zeta) - \tau(z_2))(\tau(\zeta) - \tau(z_1))} + \int_{D} \frac{d\tau(\zeta) \wedge d\overline{\tau(\zeta)}}{\tau(\zeta) - \tau(z_1)} + \int_{D} \frac{d\tau(\zeta) \wedge d\overline{\tau(\zeta)}}{\tau(\zeta) - \tau(z_2)}.
\]

The last two integrals can be estimated by a standard argument for Hölder estimates, bounded in absolute value by \( C_0\|f\|_{t,0}\|z_2 - z_1\|^\alpha \). The first integral can be rewritten as the product of \( f(z_1) - f(z_2) \) and \( \mathcal{I} \) where

\[
\mathcal{I} := \int_{D} \frac{d\tau(\zeta) \wedge d\overline{\tau(\zeta)}}{(\tau(\zeta) - \tau(z_2))(\tau(\zeta) - \tau(z_1))} + \int_{D} \frac{d\tau(\zeta) \wedge d\overline{\tau(\zeta)}}{\tau(\zeta) - \tau(z_1)} + \int_{D} \frac{d\tau(\zeta) \wedge d\overline{\tau(\zeta)}}{\tau(\zeta) - \tau(z_2)} = 2\pi i \epsilon \int_{D} \frac{\tau(z_2) - \tau(z_1)}{\tau(z_1) - \tau(z_2)} + \frac{1}{\tau(z_1) - \tau(z_2)} \int_{\partial D} \frac{\overline{\tau(\zeta)} d\tau(\zeta)}{\tau(\zeta) - \tau(z_2)}.
\]

A derivative of \( \int_{\partial D} \frac{\overline{\tau(\zeta)} d\tau(\zeta)}{\tau(\zeta) - \tau(z_2)} \) is \( \partial_\tau(z) \int_{\partial D} \frac{d\tau(\zeta)}{\tau(\zeta) - \tau(z_2)} \) which, by \((ii)\), is bounded. By the mean-value-theorem, the last term in \( \mathcal{I} \) is bounded. This shows that \( S_0 f \in C^{t,0}(\mathbb{D}^+_r, P) \).

For higher order derivatives, we transport derivatives to \( f \). Define \( f_*(\tau(z)) := f(z) \) and \( \omega(t) := \tau(\cdot, t)(D) \). Let \( C_* := C_{\omega(t)}, T_* := T_{\omega(t)} \) and \( S_* := S_{\omega(t)} \). Rewrite (4.5) as \( g_*(\tau) = \epsilon S_* f_* \). By integrating by parts, we obtain

\[
g_*(\tau) = \frac{1}{2\pi i} \int_{\omega(t)} \frac{\partial f_*(\zeta)}{\zeta - \tau} d\zeta \wedge d\overline{\zeta} - \frac{1}{2\pi i} \int_{\partial \omega(t)} \frac{f_*(\zeta)}{\zeta - \tau} d\zeta.
\]

On \( \partial \omega(t) \), we write \( d\overline{\tau} = a(\tau, t) d\tau \) with \( a \in C^{k+\alpha,0}(\partial D, P) \). Taking derivatives, we get

\[
\partial_\tau S_* f_* = \partial_* f_* , \quad \partial_* S_* f_* = S_* \partial_\tau f_* - \partial_\tau C_* a f_* .
\]

Using the last formula \( k \) times, we get

\[
(\partial_\tau)^k S_* f_* = S_* \partial_\tau^k f_* - \sum_{0 \leq j < k} \partial_\tau^{k-j} C_* a \partial_\tau^j f_* .
\]
Let \( \Omega \) be a domain, and \( \partial \) denote differentiation. Then for any \( \Omega \) in \( \mathbb{C} \), the \( K \) from the assertion for polynomials, and \( q \) regularity of Theorem 5.1. 

Here the integral operator \( S \) is over the domain \( D \), and \( C_0 \) is over \( \partial D \). \( p_j \) are vectors of polynomials, and \( q_{j,k}, q_{k}^1, q_{j}^3 \) are matrices of polynomials in \((\det \tau)^{-1} \) and \( \partial_{z_j} \tau \). It follows from the assertion for \( k = 0 \) and (ii) that \( S_0 f \in C^{k+\alpha,0}(\overline{\Omega}^+,P) \).

Note that \( \partial_z \tau = S_\tau \) and \( \partial_\tau \tau = 1 \). Thus it follows from (ii), the product rule, and the chain rule as used in (4.6), that \( T_0 f \in C^{k+\alpha,0}(\overline{\Omega}^+,P) \).

5. Proof of the main theorem

Let \( \Delta := [-1,1] \) and \( \Delta_r := [-r,r] \). Let \( \Delta_1^n, \Delta_2^{2n-1}, \Delta_r^{2n} \) be the corresponding cubes in the \( x \)-subspace, hyperplane \( y_n = 0 \), and \( \mathbb{R}^{2n} \), respectively.

In this section, we state and prove a more precise version of Theorem 1.1.

**Theorem 5.1.** Let \( k \geq 3 \) be an integer. Let \( \Omega_1, \Omega_2, M, \alpha \) be as in Theorem 1.1 with \( M \in C^{k+\alpha} \). For \( l = 1,2 \), let \( J^l \) be an almost complex structure of class \( C^{k+\alpha}(\Omega \cup M) \) on \( \Omega \cup M \). Suppose that at each point \( p \in M \) there is a tangent vector \( v_p \in T_p M \) such that \( J_p^1 v_p, J_p^2 v_p \) are in the same connected component of \( T_p \mathbb{R}^{2n} \setminus T_p M \). Let \( f \) be a continuous function on \( \Omega \cup M \) such that \((\partial_{x_j} + iJ^l \partial_{x_j}) f \) and \((\partial_{y_j} + iJ^l \partial_{y_j}) f \) defined on \( \Omega \), extend to functions in \( C^k(\Omega \cup M) \) for \( l = 1,2 \) and \( 1 \leq j \leq n \). Then \( f \in C^{k-2}(\Omega \cup M) \cap C^{k-2+\beta}(\Omega) \) for any \( \beta < 1 \).

Notice that no integrability condition is assumed. A by-product of our proof is an interior regularity of \( f \) with \( f \in C^\beta(\Omega) \) for any \( \beta < k = 2 \); of course, the assumptions on \( f, J^2 \), \( M \) and \( \Omega_2 \) are not needed in order to obtain the regularity of \( f \) on \( \Omega_1 \). The result might not be sharp. Indeed, when the structures are integrable and \( k \geq 1 \), the Newlander-Nirenberg theorem [25] yields \( f \in C^{k+\beta}(\Omega) \) for any \( \beta < 1 \).

We first describe the main ingredients of the proof.

**Step 1.** Let \( \Omega^+ = \Omega_1 \) and \( \Omega^- = \Omega_2 \). We first assume the interior regularity that \( f \) is \( C^1 \) on \( \Omega^+ \cup \Omega^- \). We will show that the Fourier transforms of \( f \) on lines \( L \) in \( M \) decay in the \( \xi \)-variable. To use the differential equations for \( f \), lines \( L \) need to be transversal to the complex tangent vectors of \( M \) of both structures. Two almost complex structures yield decay of the Fourier transform at opposite rays. This is the only place we need both structures. According to Proposition 3.9, this gives the smoothness of \( f \) on \( M \).

**Step 2.** In order to obtain the smoothness of \( f \) on each side of \( M \) (up to the boundary) via the one-sided almost complex structure, we attach a family of pseudoholomorphic discs to \( M \) by using Proposition 3.7. Such a disc will have regularity as good as the structure provides. This is achieved by extending the structure to a neighborhood of \( M \). Using
Lemma 4.1, we prove that the regularity of $f$ on $M$ yields uniform bounds of pointwise derivatives of $f$ along the discs up to their boundaries in $M$.

Step 3. After obtaining the smoothness of $f$ on families of discs in $\Omega^+ \cup M$, we obtain the interior regularity of $f$, including the $C^1$ regularity, by Proposition 3.9. Using Proposition 3.9 again, we conclude the smoothness of $f$ on $\Omega^+ \cup M$.

We now carry out details. We need a preparation for Step 1.

Step 0. Match approximate $J$-holomorphic half-discs in $M$.

We fix a finite integer $k \geq 3$. We may assume that $M = \Delta^{2n-1} \times 0$, $\Omega^+ = \mathbb{D}^n \cap \{y_n > 0\}$ and $\Omega^- = \mathbb{D}^n \cap \{y_n < 0\}$. By assumption, there is a vector $v_0 \in T_0M$ such that the vectors $J_0^1v_0, J_0^2v_0$ are transversal to $T_0M$ and are in $\Omega^+$. Thus the line segments $tJ_0^1v_0, tJ_0^2v_0$ $(0 < t \leq 1)$ are transversal to $M$ and are contained in $\Omega^+$, by shrinking $v_0$ if necessary. Here we have identified $\mathbb{R}^{2n}$ with $T_p\mathbb{R}^{2n}$ by sending $v$ to the tangent vector of $p + tv$; consequently, $J_p^1$ acts on $\mathbb{R}^{2n}$ linearly.

Let $\epsilon > 0$ be sufficiently small such that if $p \in M$ and $v \in T_pM$ satisfy $|p| < \epsilon$ and $|v - v_0| < \epsilon$. Then $J_p^1v$ and $J_p^2v$ are still in the same component of $T_p\mathbb{R}^{2n} \setminus T_pM$. By transversality, $p + tJ_p^1v$ and $p + tJ_p^2v$ are in $\Omega^+$ for $0 < t \leq 1$. Define the line segment

$$L = L(v, p) := \{p + tv: -2 < t < 2\} \subset M.$$ 

Let $e_1, \ldots, e_{2n-1}$ be the standard basis of $\mathbb{R}^{2n-1}$. We find an affine coordinate map $\phi$ on $\mathbb{R}^{2n}$ such that $\phi(p) = 0$, $\phi(p + v) = e_1$, and $\phi(p + v_j) = e_j$. We may also assume that the norms of $\phi$ and $\phi^{-1}$ have an upper bound independent of $p$ and $v$. In what follows, all constants are independent of $p$ and $v$. Proposition 3.9 (ii) will be used for this family of $\phi$ (with $p = 0$) depending on parameter $v$ with $v_0$ to be chosen.

We want to apply Lemma 3.6 to $L(v, p)$. Here $v$ and $p$ are considered as parameters and we suppress them in all expressions. For the above $L(p, v)$, we attach an approximate $J$-holomorphic curve $u^1$ of class $C^{k+1+\alpha}$ such that

$$du^1(\partial_z) = V^1(z) \cdot X^1(u^1(z)) + F^1(z) \cdot \overline{X^1(u^1(z))},$$

$$|F^1(z)| \leq C|y|^{k+\alpha}, \quad (x, y) \in Q := (-1, 1) \times (0, \epsilon).$$

We have an analogous $u^2$ and $\Omega^- \cup M$. We also require

$$u^1(x, 0) = p + xv = u^2(x, 0) \text{ on } [-1, 1].$$

We know that $u^1(x, 0)$ is contained in $M \subset \overline{\Omega^+} \cap \overline{\Omega^-}$ for $|x| < 1$. When $p = 0$ and $v = v_0$, we have $du^1(0)(\partial_x) = v_0$ and $du^1(0)(\partial_y) = J_0^1du^1(0)(\partial_x) = J_0^1v_0$ is contained in $\Omega^+$, $-J_0^2v_0$ is contained in $\Omega^-$ and both are transversal to $M$. Thus,

$$u^1(x, y) \in \Omega^+, \quad (x, y) \in Q; \quad u^2(x, y) \in \Omega^-, \quad (x, y) \in -Q.$$ 

The above hold for $v = v_0$ and $p = 0$. Since the derivatives of $u$ are continuous in $p$ and $v$, the above hold for $|p| < \epsilon$ and $|v - v'| < \epsilon$. And for a constant $C > 1$ independent of $p$ and $v$, we have

$$\text{dist}(u^1(x, y), M) \geq |y|/C, \quad (x, y) \in (-1)^{l-1}Q.$$
Step 1. Uniform bound of Fourier transform of $f$ on transversal lines $L$ in $M$.

In Steps 1 and 2, we will assume that $f$ is $C^1$ on $\Omega^+ \cup \Omega^-$. We will verify this interior regularity in the final step.

Fix $k$. Recall from Step 0 that $M$ is contained in $\mathbb{R}^{2n-1}$. Let $v_0, \epsilon$ be as in Step 0. By Lemma 3.8, there exist $N$ vectors $v_j$ in $\mathbb{R}^{2n-1}$ such that

$$ (\partial_x, \partial_y)^I = \sum_{1 \leq j \leq N} c_{I,j}(v_j \cdot (\partial_x, \partial_y))|^{11}, \quad 1 \leq |I| \leq k. $$

Here $|v_j - v_0| < \epsilon$. Recall that the line segment $L$ is $\{p + tv : -1 \leq t \leq 1\}$ with $p \in M$ such that $|p| < \epsilon$. Fix such a segment $L$ and denote its tangent vector $v_j$ by $v$.

Note that when $\epsilon$ is sufficiently small, $L$ has length $> |v_0|/2$. Let $\chi_0$ be a cutoff function on $M$ with compact support in $\Delta_{X_0/(\epsilon n)} \cap M$. Then $\chi_0|_L$ has compact support. We will show that the Fourier transform of $\chi_0 f$ on $L$ satisfies

$$ \int \psi L(\xi) \leq C_\beta $$

for any $\beta > 0$, where $C_\beta$ will be independent of $p, v_1, \ldots, v_d$. We will verify (5.5) for $\xi = -|\xi|v$, using $X_1 f = g_1$ on $\Omega^+$ with $g_1 \in C^k(\Omega^+ \cup M)$. For $\xi = |\xi|v$, we use $X_2 f = g_2$ on $\Omega^-$ with $g_2 \in C^k(\Omega^- \cup M)$.

We now use approximate $J$-holomorphic curves $u^1, u^2$ defined in Step 0. We drop the superscript in $u^1, g^1, a^1_{jk}, \ldots$. Applying Lemma 2.3, we extend $\chi_0 \circ u(x,0)$ to $\chi \in C^\infty(Q)$ which has compact support in each $(-1,1) \times \{y\}$. Moreover, $|\partial_x \chi(x,y)| \leq C|y|^{k+\alpha}$. For brevity, denote $f \circ u$ and $g_j \circ u$ by $f$ and $g_j$. Combining with (5.1), we get on $Q$

$$ \partial_y f(x,y) = i\partial_x f(x,y) - 2iV(x,y) \cdot g(u(x,y)) - 2iF(x,y) \cdot \overline{X(u)f}, $$

$$ \partial_y \chi(x,y) = i\partial_x \chi(x,y) + E(x,y). $$

Moreover $|E| + |F|(x,y) \leq C|y|^{k+\alpha}$, and $V, E, F$ are in $C^{k+\alpha}(\overline{Q})$, and $g$ is in $C^k(\overline{Q})$.

In what follows, as required by (5.5) constants do not depend on $L, p, v_j$. By (5.2), $u(x,y)$ is in $\Omega^+$ for $|x| < 1, 0 < y < \epsilon$. Define for $y \geq 0$

$$ \lambda(\xi, y) := \int_R (\chi f)(x,y)e^{-i(x+iy)\xi} dx. $$

Notice that

$$ \overline{\chi f}_L(\xi) \equiv \lambda(\xi, 0) = \lambda(\xi, \eta) - \int_0^\eta \partial_y \lambda(\xi, y) dy. $$

By (5.6), we obtain

$$ \partial_y \lambda(\xi, y) = \int_R i\partial_x [(\chi f)(x,y)e^{-i(x+iy)\xi}] dx $$

$$ - 2i \int_R (g(u) \cdot V \chi)(x,y)e^{-i(x+iy)\xi} dx + \int_R (f(u)E)(x,y)e^{-i(x+iy)\xi} dx $$

$$ - 2i \int_R \chi F(x,y) \cdot (\overline{X f})(u(x,y))e^{-i(x+iy)\xi} dx. $$
By integrating by parts, the first integral is zero. Since \( g(u(x, y)), V(x, y) \in C^k \) and \( y|\xi| \leq 0 \), the second one, via integrating by parts \( k \) times, is bounded by \( C(1 + |\xi|)^{-k} \). The third one is bounded by \( C|E(x, y)| \) ≤ \( Cy^{k+\alpha} \).

We now estimate the last integral. This amounts to controlling the blow-up of derivatives of \( f \) at \( u(x, y) \), for which we apply Proposition 3.7 to a domain of fixed size. By (5.3), \( \Omega^+ \) contains \( \mathbb{D}^n_{y/C}(u(x, y)) \). Let \( \bar{w} = \psi(w) := u(x, y) + yw/C \) with \( w \in \mathbb{C}^n \). So \( \psi^{-1} \) transforms \( J, X_1 \) into \( J, \bar{X}_1 = C^{-1} y \psi^{-1} X_1 \). On \( \mathbb{D}^n \), we have

\[
\bar{X}_I = \sum_{1 \leq s \leq n} (b_{ts} \circ \psi \partial_{w^s} + a_{ts} \circ \psi \partial_{\bar{w}^s}).
\]

Let \( A' := (a_{ts} \circ \psi) \) and \( B' := (b_{ts} \circ \psi) \). It is easy to see that on \( \mathbb{D}^n \), \( \inf \frac{|A'|^2}{|B'|} \geq 1/C \) and \( \|A', B'\|_{10+} \leq C \) for some constant independent of \( v \) and \( p \). Fix \( 1 \leq m \leq 2n \) and let \( (\bar{w}_1, \ldots, \bar{w}_{2n}) \) be the standard coordinates of \( \mathbb{R}^{2n} \). Applying Proposition 3.7 to \( \{\bar{X}_j\} \), we get a \( J \)-holomorphic curve \( \bar{u}: \mathbb{D}_r \to \mathbb{D}^n \) satisfying \( \bar{u}(0) = 0 \) and \( d\bar{u}(0)(\partial_\zeta) = \partial_{\bar{w}'_m} - iJ_0 \partial_{\bar{w}'_m} \).

Here \( r > 0 \) is a constant independent of \( y \), and \( |\partial^j \bar{u}| < C \) for \( j \leq k + 1 \). Then the disc \( \bar{u}(\zeta) := \psi \circ \bar{u}(C\zeta/y) \) is \( J \)-holomorphic. We have \( \bar{u}: \mathbb{D}_{y/c} \to \Omega^+_1 := \psi(\Omega^+) \), \( \bar{u}(0) = u(x, y) \), and

\[
d\bar{u}(0)(\partial_\zeta) = \partial_{\bar{w}'_m} - iJ_{\bar{u}(0)} \partial_{\bar{w}'_m}.
\]

So \( d\bar{u}(0)(\partial_\zeta) = \partial_{\bar{w}'_m} + iJ_{\bar{u}(0)} \partial_{\bar{w}'_m} \). A direct computation shows that the first and second order derivatives of \( \bar{u} \) are bounded by \( C \) and \( C/y \), respectively. It follows that \( d\bar{u}(\partial_\zeta) = \bar{V}(\zeta) \cdot X(\bar{u}(\zeta)) \) and the first-order derivative of \( \bar{V}(\xi, \eta) \) is bounded by \( C/\eta \). Let \( g_j := X_j f \).

We obtain

\[
\partial_\xi(f(\bar{u}(\zeta))) = g(\bar{u}(\zeta)) \cdot \bar{V}(\zeta).
\]

By the Cauchy-Green identity, we have

\[
f(\bar{u}(\zeta)) = \frac{1}{2\pi i} \int_{|\xi| = y/c} \frac{f(\bar{u}(\zeta_s))}{\zeta_s - \zeta} d\zeta_s + \frac{1}{\pi} \int_{|\xi| < y/c} \frac{g(\bar{u}(\zeta_s)) \cdot \bar{V}(\zeta_s)}{\zeta_s - \zeta} d\zeta_s d\eta_s.
\]

At \( \zeta = 0 \), the first-order derivatives of the first integral are bounded by \( C/y \). Write \( g(\bar{u}(\zeta)) \cdot \bar{V}(\zeta) \) as \( h_1(\zeta) + h_2(\zeta) \). Here \( C^1 \) norms of \( h_1, h_2 \) are bounded by \( C/y, h_1(\zeta) = 0 \) on \( |\zeta| < y/(4c) \), and \( h_0(\zeta) = 0 \) on \( |\zeta| > y/(2c) \). The first-order derivatives of the integral involving \( h_1 \) are bounded by \( C \) at \( \zeta = 0 \). After applying a translation \( \zeta' = \zeta_s - \zeta \), the integral involving \( h_0 \) has bounded derivatives at \( z = 0 \) too. We obtain

\[
2|\langle \partial_{\bar{w}'_m} f(\bar{u}(0)) \rangle| = |\partial_\xi(f(\bar{u}))(0) + \partial_\zeta(f(\bar{u}))(0)| \leq C/y.
\]

Thus,

\[
|\partial_\mu \lambda(\xi, y)| \leq C \left( y^{k-1+\alpha} + (1 + |\xi|)^{-k} \right).
\]

We also have for \( \eta \xi \leq 0 \)

\[
|\lambda(\xi, \eta)| \leq Ce^{\eta \xi} \leq CL|\eta \xi|^{-L}.
\]
We may assume that \( \xi \leq -1 \). For \( 0 < \alpha' < \alpha \), choose \( \eta = 1/(C|\xi|^{1-\varepsilon}) \) with \( \varepsilon > 0 \) sufficiently small. Finally, \( \lambda(\xi,0) = \lambda(\xi,\eta) - \int_0^\eta \partial_y \lambda(\xi,y) \, dy \) satisfies

\[
(5.7) \quad |\lambda(\xi,0)| \leq C_L(C^{-1}|\xi|^\varepsilon)^{-L} + \frac{C}{k+\alpha} \eta^{k+\alpha} + C(1+|\xi|)^{-k} \frac{1}{C|\xi|^{1-\varepsilon}}
\]

\[
\leq C_{\alpha'}(1+|\xi|)^{-(k+\alpha')}
\]

for \( \xi \leq 0 \). Reasoning with \( X_j^2 f = g_j^2 \) for \( y_n \leq 0 \) and \( u^2 \), we get (5.7) for \( \xi \geq 0 \) and hence for \( -\infty < \xi < \infty \).

By the Fourier inversion formula,

\[
\chi f(p+xv) = \frac{1}{2\pi} \int_R \lambda(\xi,0) e^{i\xi x} \, d\xi,
\]

\[
\partial_{\xi}^{k-1}(\chi f(p+xv)) = \frac{1}{2\pi} \int_R \lambda(\xi,0) (i\xi)^{k-1} e^{i\xi x} \, d\xi.
\]

Using (5.7), we obtain \( \chi f(p+xv) \in C^{k-1} \). Let \( 0 < \alpha'' < \alpha' < \alpha \). Note that \( |e^{ix2} - e^{ix1}| \leq 2|x_2 - x_1|^{\alpha''} \) for all real numbers \( x_1, x_2 \). By (5.7) and (5.8) again, we obtain

\[
|\partial_{\xi}^{k-1}(\chi f)(p+x2v) - \partial_{\xi}^{k-1}(\chi f)(p+x1v)| \leq C_{\alpha'} \int_R \frac{|x_2-x_1|^{\alpha''} |\xi|^{\alpha''}}{(1+|\xi|)^{1+\alpha'}} \, d\xi.
\]

We have \( |(\chi f(p+\cdot v))|_{k-1+\alpha''} < C_{\alpha''} \). Therefore,

\[
|\lambda_0 f|_{k-1+\alpha''} < C_{\alpha''},
\]

where \( L \) is any line which is tangent to one of \( v_1, \ldots, v_N \) and which passes through \( p \in M \) near the origin. For such a line \( L \), we can find an affine diffeomorphism \( R \) with \( R(0) = 0 \in M \), sending \( \Delta^{2n-1} \) into \( M \), such that \( R(\cdot, t) \) are lines parallel to \( L \) for \( t \in \mathbb{D}^{n-1} \). By Proposition 3.9 (ii) and hypothesis (5.4), we get \( \partial^{k-2}(\chi_0 f) \in Lip(M) \).

**Step 2. Uniform bound of derivatives of \( f \) on transversal \( J \)-holomorphic curves.**

By Lemma 3.8, there exist \( N \) vectors \( v_j \in \mathbb{R}^{2n} \) with \( |v_j| < 1 \) such that

\[
(5.9) \quad (\partial_x, \partial_y)^I = \sum_{1 \leq j \leq N} c_{I,j} (v_j \cdot (\partial_x, \partial_y)) |I|, \quad 1 \leq |I| \leq k.
\]

By perturbing \( v_j \), we may assume that \( J_p(v_j \cdot (\partial_x, \partial_y)) \) are not tangent to \( M \) at \( p = 0 \) and hence in a neighborhood of \( 0 \) in \( M \).

We are given \( n \) vector fields \( X_1, \ldots, X_n \) defined on \( \Omega^+ \cup M \). Recall that \( M \) is contained in \( y_n = 0 \) and \( \Omega^+ \) is contained in \( y_n > 0 \). Applying Borel theorem (Lemma 2.3) via restriction and then extension, we may assume that \( X_1, \ldots, X_n \) define an almost complex structure on a neighborhood of \( M \). We emphasize that even if we start with an integrable almost complex structure, the resulting almost complex structure may not be integrable. We now apply Proposition 3.7 with the parameter set \( P = \mathbb{D}^{n-1}_{\rho_0} \). We find diffeomorphisms \( u_j, R_j \) of class \( C^{k+1+\alpha,k} \), which maps \( \mathbb{D}_{\rho_0} \times \mathbb{D}^{n-1}_{\rho_0} \) into \( \Omega \) and such that

\[
(5.10) \quad du_j(0,t)(\partial_x) = v_j \cdot (\partial_x, \partial_y).
\]

Moreover, \( D_{j,r}(t) := u_j(\mathbb{D}_r,t) = R_j(\omega_{j,r}(t),t) \) satisfy

\[
\mathbb{D}_{r/c_1} \subset \omega_{j,r}(t) \subset \mathbb{D}_{c_1 r}.
\]
Also $R_j(0) = 0$, $u_j(0) = 0$, and

$$-2i du_j(\cdot, t)(\partial_{\bar{z}}) = J_0(v_j \cdot (\partial_x, \partial_y)) - i(v_j \cdot (\partial_x, \partial_y)).$$

We choose $r < r_0$ sufficiently small so that various compositions in $u_j, R_j$ are well-defined. Also $\omega_{j,r}^+(t) := \omega_j(t) \cap \{ y > 0 \}$ satisfies $R_j(\omega_{j,r}^+(t), t) = D_{j,r}^+(t) := D_{j,r}(t) \cap \Omega^+$. Write $(\tilde{D}_{j,r}^+(t), t) = u_j^{-1}(D_{j,r}(t))$. According to the Cauchy-Green formula, we have

$$f(u_j(\tilde{z}, t)) = \frac{1}{2\pi i} \int_{\partial D_{j,r}^+(t)} \frac{f(u_j(\tilde{z}, t))}{\tilde{z} - \zeta} \, d\tilde{z} = \frac{1}{2\pi i} \int_{\partial D_{j,r}^+(t)} \frac{\partial_{\bar{z}} f(u_j(\tilde{z}, t))}{\tilde{z} - \zeta} \, d\tilde{z} - \frac{1}{2\pi i} \int_{\partial D_{j,r}^+(t)} \frac{\partial_{\bar{z}} f(u_j(\tilde{z}, t))}{\tilde{z} - \zeta} \, d\zeta \wedge d\tilde{z}.$$

Set $(\tilde{z}, t) = u_j^{-1} \circ R_j(z, t) = (\tau_j(z, t), t)$. By $du_j(\partial_{\bar{z}}) = V(\zeta) \cdot X(u_j(\zeta))$ and $X_j f = g_j$, we get $\partial_{\bar{z}} f(u_j) = V \cdot g(u_j)$ and

$$\epsilon f(R_j(z, t)) = \frac{1}{2\pi i} \int_{\zeta \in \partial \omega_{j,r}^+(t)} \frac{f(R_j(\zeta, t))}{\tau_j(\zeta, t) - \tau_j(z, t)} \, d\tau_j(z, t) - \frac{1}{2\pi i} \int_{\omega_{j,r}^+(t)} \frac{g(R_j(\zeta, t)) \cdot V(\tau_j(\zeta, t))}{\tau_j(\zeta, t) - \tau_j(z, t)} \, d\tau_j(\zeta, t) \wedge d\tau_j(z, t).$$

Here $\epsilon = 1$ if $\tau_j(\cdot, t)$ is orientation-preserving and otherwise $\epsilon = -1$. Notice that $\epsilon$ is independent of $t$. Recall that $R_j(\cdot, t)$ sends $[-r/c, r/c]$ into $\partial D_{j,r}^+(t) \cap M$. Since $u \in C^{k+1+\alpha,k}$, it is easy to see that $V(\tau_j(\zeta, t))$ are in $C^{k+\alpha,0}$. Applying Lemma 4.1 (ii), $\partial_{\bar{z}}^{k+1}(f(R_j))$ are continuous on $\Delta_{r/c} \times [0, r/c] \times \mathbb{D}^{n-1}_{r/c}$. And on it, $|f(R_j)|_{k-2+\beta,0} < C_\beta$ for any $\beta < 1$, where $\mathbb{D}^{n-1}_{r/c}$ is the parameter space.

**Step 3. Smoothness of $f$ via families of $J$-holomorphic curves.**

In this step, we will first remove the assumption stated at the beginning of Step 1 that $f$ is $C^1$ on $\Omega_t$. We also address the comment made after Theorem 5.1 on the interior regularity of $f$. Let $J = J_t \in C^{k+\alpha}$ and $\Omega = \Omega_t$. Here we again need $k \geq 3$.

Let $u_j$ satisfy (5.9). According to Proposition 3.7, we find a $C^{k+1+\alpha,k}$ diffeomorphism $u_j$ defined in neighborhood of $0 \in \Omega$ such that $\zeta \mapsto u_j(\zeta, t)$ is $J$-holomorphic for fixed $t \in \mathbb{D}^{n-1}_\epsilon$ and $u_j(0) = 0, du_j(0)(\partial_{\bar{z}}) = v_j$. Drop the subscript $j$ in $u_j$. Then $u^{-1}$ defines a $C^k$ coordinate system in a neighborhood of the origin, and $u^{-1}$ transforms $J$ into $\hat{J}$. It follows that $\hat{D}_\epsilon \times \{t\}$ are $J$-holomorphic curves for $|t| < \epsilon$ and $\epsilon$ small enough. Thus we can take $\hat{X}_1 = a(\zeta, t)\partial_{\bar{z}} + b(\zeta, t)\partial_\zeta$ with $a, b \in C^{k+\alpha,k}$ and $t$ being the parameter. Now $\hat{f} := f \circ u$ satisfies $\hat{X}_1 \hat{f} = \hat{\gamma}_1 \in C^k$. Here $\hat{X}_1 \hat{f} = \hat{\gamma}_1$ holds in the sense of distributions. We want to show that when restricted to $\hat{D}_\epsilon \times \{t\}$, $\hat{X}_1 \hat{f} = \hat{\gamma}_1$ still holds as distributions. To verify it, we fix a test function $\phi$ on $\hat{D}_\epsilon$ and take a sequence of test functions $\phi_\nu$ in $C^{n-1}$ such that $\int_{\mathbb{C}^{n-1}} \phi_\nu = 1$ and $\text{supp} \phi_\nu \subset \{t\} + \mathbb{D}^{n-1}_{1/\nu}$. Note that the formal adjoint $\hat{X}_1^* \hat{f}$ does not contain derivatives in the $t$-variable and satisfies

$$\int_{\mathbb{C}^n} \hat{\gamma}_1 \phi \phi_\nu = \int_{\mathbb{C}^n} \hat{f} \hat{X}_1^* (\phi \phi_\nu) = \int_{\mathbb{C}^n} \hat{f} \phi_\nu \hat{X}_1^* (\phi).$$

Since all functions in the integrands are continuous, as $\nu$ tends to $\infty$ we obtain

$$\int_{\mathbb{C}} \hat{\gamma}_1(\cdot, t) \phi = \int_{\mathbb{C}} \hat{f}(\cdot, t) \hat{X}_1^* (\phi).$$
Thus we have proved that in the sense of distributions $\hat{X}_1 f = \hat{g}_1 \in C^k \subset C^{k-1+\beta}$ for any $\beta < 1$. The coefficients of $\hat{X}_1$ are in $C^{k+a,k}$. Reasoning as at the end of Step 2 by using Lemma 4.1 (i) and (iii), we obtain $f \circ u_j \in C^{k+\beta,0}$ for any $\beta < 1$. (Note that this part of Step 2 does not use the assumption that $f \in C^1$.) Now $f \circ u_j \in C^{k-1,0}$ with $k-1 \geq 1$, $u_j \in C^k$ and Proposition 3.9 (iii) implies that $f \in C^{k-2+\beta}$ for all $\beta < 1$. In particular, we get $f \in C^1$ on $\Omega_1 \cup \Omega_2$ for $k \geq 3$, which is used in Steps 1 and 2.

We now finish the proof of the theorem. By the end of Step 2, we know that when $r$ is sufficiently small, $\partial_{\xi,\eta}^k (f \circ R_j (\xi + i\eta,t))$ are continuous on $\mathbb{D}^2 \cap \{ \eta \geq 0 \}$. Assume that $k > 2$. We also know that the $C^k$ diffeomorphisms $R_j, u_j$ satisfy $u_j(0) = R_j(0) = 0 \in M, R_j(\omega_{j,r}(t),t) = u_j(\mathbb{D}_r,t)$ and $R_j(\omega_{j,r}(t) \cap \{ \eta \geq 0 \},t) = u_j(\mathbb{D}_r,t) \cap \overline{\mathbb{D}}^+$. Thus $(\partial_{\xi,\eta}^k (f \circ u_j)) \circ u_j^{-1}$ are continuous on $\mathbb{D}^2 \cap \overline{\mathbb{D}}^+$. Since $du_j(0,t)(\partial_\xi) = v_j \cdot (\partial_\xi, \partial_\eta)$, in view of (5.9) we can apply Proposition 3.9 to the family of diffeomorphisms $u_j(\xi + i\eta,t)$ by treating $(\eta,t)$ as parameters. Since $f \in C^{k-2}(\Omega^+)$, using Proposition 3.9 (i) we express $\partial^j f$ on $\Omega^+ \cap \Delta^{2n}$ via functions $(\partial_{\xi,\eta}^k (f \circ u_j)) \circ u_j^{-1}$ for $1 \leq |l| \leq k-2$. The latter are continuous on $\overline{\Omega}^+ \cap \mathbb{D}_1$. We have proved that $\partial^j f(x)$ extends continuously to $\overline{\Omega} \cap \Delta^{2n}$ for all $|l| \leq k-2$ and $k > 2$. Therefore, $f \in C^{k-2}(\Omega^+ \cup M)$ by $M \in C^{k-2}$. The proof of Theorem 5.1 is complete.

6. One-dimensional Riemann mapping for structures with parameter

Throughout this section, $\Omega$ is a bounded open set in $\mathbb{C}$. We start with the existence of isothermal coordinates with parameter. Recall that a diffeomorphism $\varphi$ is said to transform a vector field $X$ into $\tilde{X}$ if locally $d\varphi(X) = \mu \tilde{X}$. Denote by $\hat{C}^{k+\alpha,j}(\Omega \cup \gamma, P)$ the set of functions which are in $\hat{C}^{k+\alpha,j}(K, P)$ for any compact subset $K$ of $\Omega \cup \gamma$ where $\gamma$ is an embedded curve. Set $\hat{C}^{k+\alpha,j}(\Omega \cup \gamma, P) := \bigcap_{0 \leq \alpha \leq k} \hat{C}^{k-\alpha+\alpha,j}(\Omega \cup \gamma, P)$ for $k \geq j$. Recall that $\hat{C}^{\infty,j}(\Omega, P) = \bigcap_{k=1}^\infty \hat{C}^{k,j}(\Omega, P)$ and set $\hat{C}^{\infty,\infty}(\Omega, P) := \bigcap_{j=1}^\infty \hat{C}^{\infty,j}(\Omega, P)$.

**Proposition 6.1.** Let $k, j$ be integers or $\infty$ such that $j \leq k$ and let $0 < \alpha < 1$. Let $\Omega$ be a domain in $\mathbb{C}$ and $P$ be an open set in an Euclidean space. Let $a \in \hat{C}^{k+\alpha,j}(\Omega, P)$ (resp. $\hat{C}^{k+\alpha,j}(\Omega, P)$) satisfying $|a|_{\infty} < 1$. If $x \in \Omega$ there exist a neighborhood $U$ of $x$ and a map $\varphi \in \hat{C}^{k+\alpha,j}(U, P)$ (resp. $\hat{C}^{k+\alpha,j}(U, P)$) such that $\varphi(\cdot, t)$ are diffeomorphisms which map $U$ onto their images and $\partial_{x} + a(z, t) \partial_{z}$ into $\partial_{z}$.

**Proof.** Fix $x = 0 \in \Omega$. Let $\varphi(z,t) = z - a(0,t) \tau$. Then $z \mapsto \varphi(z, t)$ is invertible and transforms $\partial_{z} + a(z,t) \partial_{z}$ into $\partial_{z} + \tilde{a}(z,t) \partial_{z}$ with $\tilde{a}(0, t) = 0$. The problem is local. By dilation, we may assume that $\Omega$ contains $\mathbb{D}$. Let $\chi$ be a smooth function on $\mathbb{D}$ which has compact support and equals 1 on $\mathbb{D}_{1/2}$. Applying a dilation and replacing $\tilde{a}$ by $\chi \tilde{a} = b$, we achieve $|b|_{a,0} < \epsilon_\alpha$ on $\mathbb{D}$ for the $\epsilon_\alpha$ in Lemma 2.2. Set $f := -(1+Tb \partial_{\tau})^{-1} T b$. On $\mathbb{D}$, we have $f \in \hat{C}^{k+1+\alpha,j}$ and $|f|_{1,0} \leq C_{\alpha}(1+Tb \partial_{\tau})^{-1} |1+a,0|_{b,0}$. With the dilation for $\tilde{a}$, $|f|_{1,0}$ can be arbitrarily small. Therefore $z \mapsto z + f(z,t)$ are indeed diffeomorphisms. Since $z + f(z,t)$ is annihilated by $\partial_{z} + \tilde{a}(z,t) \partial_{z}$ into $\partial_{z}$.

It is important that the above classical result (for the non-parameter case) allows one to interpret $\partial_{z} f + a \partial_{z} f = g$ when $a$ is merely $C^\alpha$. Let $w = \varphi(z)$ be a local $C^{1+\alpha}$ diffeomorphism such that $d\varphi(\partial_{z} + a \partial_{z}) = \mu(w) \partial_{w}$. Then $\partial_{z} f + a \partial_{z} f = g$ holds in the $w$-coordinates, if
Let \( f \circ \varphi^{-1} = g \circ \varphi^{-1}(w)/\mu(w) \) holds in the sense of distributions. Recall that in the proof of Theorem 1.1, there is a loss of derivatives. We now turn to a sharp version for planar domains. In fact, we will prove a parameter version.

**Theorem 6.2.** Let \( k, j \) be integers or \( \infty \) such that \( j \leq k \) and let \( 0 < \alpha < 1 \). Let \( \gamma \) be an embedded curve in \( \mathbb{C} \) of class \( C^{k+1,\alpha} \). Let \( \Omega_1, \Omega_2 \) be disjoint open subsets of \( \mathbb{C} \) such that both \( \partial \Omega_1, \partial \Omega_2 \) contain \( \gamma \) as a relatively open subset. Assume that \( a_l \in \hat{C}^{k,\alpha,l}(\Omega_l \cup \gamma, P) \) (resp. \( C^{k,\alpha,l}(\Omega_l \cup \gamma, P) \)) and satisfies \( |a_l|_{L^\infty} < 1 \) on \( (\Omega_l \cup \gamma) \times P \). Let \( f \in \hat{C}^{0,j}(\Omega_1 \cup \gamma \cup \Omega_2, P) \) and \( b_l \in \hat{C}^{k,\alpha,l}(\Omega_l \cup \gamma, P) \) (resp. \( C^{k,\alpha,l}(\Omega_l \cup \gamma, P) \)) be such that

\[
\partial_\nu f + a_l \partial_\nu f = b_l \text{ on } \Omega_l, \quad l = 1, 2.
\]

Then \( f \in \hat{C}^{k+1,\alpha,l}(\Omega_l \cup \gamma, P) \) (resp. \( C^{k+1,\alpha,l}(\Omega_l \cup \gamma, P) \)).

**Proof.** As in the proof of Theorem 1.1 in Section 5, we may assume that \( \gamma \) is the \( x \)-axis and \( \Omega_1 = \mathbb{D}_r^+, \Omega_2 = \mathbb{D}_r^- \). In the following, all functions \( a_l, b_l \), etc. are defined on \( \Omega_l \) for some \( r > 0 \) and we will take smaller values for \( r \) for a few times. Applying Lemma 2.3, we first find a function \( \phi_l \in \hat{C}^{k,\alpha,l}(\Omega_l \cup \gamma) \) such that \( \phi_l(x,0,0) = x \) and \( \partial_x \phi_l + a_l \partial_y \phi_l = O(|y|^{k+\alpha}) \). Then \( \phi_l \) sends \( \partial_x + a_l \partial_y \) into \( \mu_l(\partial_x + \tilde{a}_l \partial_y) \). Replace \( f, a_l \) by \( f \circ \phi_l^{-1}, \tilde{a}_l \) on \( \overline{\Omega}_l \). Therefore, we may assume that \( a_l(z,t) = O(|y|^{k+\alpha}) \). Now, define \( a := a_l \) on \( \overline{\Omega}_l \). It follows that \( a \) is of class \( \hat{C}^{k,\alpha,j}(\Omega_l \cup \gamma \cup \Omega_2, P) \). Set \( X := \partial_x + a(z,t) \partial_y \).

Next, we find \( g_l \in \hat{C}^{k,\alpha,l}(\Omega_l \cup \gamma, P) \) such that

\[
X g_l - b_l = O(|y|^{k+\alpha}), \quad g_l(x,0) = 0.
\]

Replace \( f \) by \( f - g_l \) on \( \overline{\Omega}_l \). Therefore, we may assume that \( b_l(z,t) = O(|y|^{k+\alpha}) \). Define \( b := b_l \) on \( \overline{\Omega}_l \). Then \( b \) is of class \( \hat{C}^{k+1,\alpha,j}(\Omega_l \cup \gamma \cup \Omega_2, P) \).

By Proposition 6.1, there are diffeomorphisms \( \psi(., t) \) with \( \psi \in \hat{C}^{k+1,\alpha,j}(\mathbb{D}_r, P) \), which send \( X \) into \( \mu \partial_x \) with \( \mu \in \hat{C}^{k,\alpha,l}(\mathbb{D}_r, P) \). Then \( \partial_x (f \circ \psi^{-1}) = b \circ \psi^{-1}/\mu \). Let \( h := T_{\mathbb{D}_r}(b \circ \psi^{-1}/\mu) \) where \( r \) is sufficiently small. Then \( h \in \hat{C}^{k,\alpha,l} \). Now \( f \circ \psi^{-1} - h \) is holomorphic away from \( \psi(\gamma) \), continuous up to the \( C^1 \) curve \( \psi(\gamma) \). Take a small disc \( D_r \), independent of \( t \) and centered at \( p \in \psi(\cdot, t_0)(\gamma) \). By the Cauchy formula, we express \( f(., t) \) on \( D_r \) via the Cauchy transform on \( \partial D_r \) when \( t \) is in a small neighborhood of \( t_0 \). From \( f \in \hat{C}^{0,j} \) and the compactness of \( P \), we conclude that \( f \in \hat{C}^{k+1,\alpha,j}(\mathbb{D}_r, P) \). Recall that \( f \) is replaced by \( f \circ \phi_l^{-1} \). Therefore the original \( f \) is in \( \hat{C}^{k+1,\alpha,j}(\Omega_l \cup \gamma, P) \).

**Lemma 6.3.** Let \( \Omega \subset \mathbb{C} \) be a bounded domain with \( \partial \Omega \in C^1 \). Suppose that \( v \in C^1(\Omega) \) and \( b \) are continuous functions on \( \overline{\Omega} \). Then \( v \) satisfies

\[
(6.1) \quad v + Tb = 0
\]

if and only if it satisfies

\[
(6.2) \quad \partial_z v + b = 0,
\]

\[
(6.3) \quad Cv = \frac{1}{2 \pi i} \int_{\partial \Omega} \frac{v(\zeta)}{\zeta - z} \, d\zeta = 0.
\]

Here three identities are on \( \Omega \). Moreover, (6.3) holds on \( \Omega \) if and only if \( v \) is the boundary value of a function that is holomorphic on \( \mathbb{C} \setminus \overline{\Omega} \), continuous on \( \mathbb{C} \setminus \overline{\Omega} \), and vanishing at \( \infty \).
Applying \( \partial_\tau \) to (6.1) gives us (6.2). On \( \Omega \), \( Cv = v - T\partial_\tau v \). Applying \( T\partial_\tau \) to (6.1) and using (6.1) again, we get \( v - T\partial_\tau v = 0 \). Conversely, if \( v \) satisfies (6.2), then \( v + Tb = v - T\partial_\tau v = Cv \). The latter is zero by (6.3). Thus \( v \) satisfies (6.1).

It is a standard fact that when \( \Omega \) is a bounded domain with \( C^1 \) boundary and \( v \) is continuous on \( \partial\Omega \), then \( Cv(z - tn(z)) - Cv(z + tn(z)) \) converges to \( v(z) \) uniformly on \( \partial\Omega \) as \( t \to 0^+ \). Here \( n \) is the unit outer normal vector of \( \partial\Omega \). Then (6.3) implies that \( Cv \) is continuous on \( C \setminus \Omega \) and agrees with \( v \) on \( \partial\Omega \). That \( Cv \) vanishes at \( \infty \) is trivial. The converse follows from the Cauchy formula.

Now, we prove a version of Theorem 1.2 with parameter.

**Theorem 6.4.** Let \( k, j \) be integers or \( \infty \) and let \( 0 < \alpha < 1 \). Let \( \Omega \) be a bounded domain in \( C \) with \( \partial\Omega \in C^{k+1+\alpha} \). Let \( a \in \hat{C}^{k+\alpha,j}(\overline{\Omega}, P), b \in \hat{C}^{k+1+\alpha,j}(\overline{\Omega}, P) \) be (scalar) functions satisfying \( \|a\|_{\alpha,0} < \varepsilon_\alpha \). Then

\[
v(\cdot, t) + T_\Omega(a(\cdot, t)\partial_\tau v(\cdot, t)) = b(\cdot, t)
\]

has a unique solution \( v(\cdot, t) \) with \( v \in \hat{C}^{k+\alpha+1+j}(\overline{\Omega}, P) \). Consequently,

\[
1 + Ta\partial_\tau : \hat{C}^{k+1+\alpha+j}(\overline{\Omega}, P) \to \hat{C}^{k+1+\alpha+j}(\overline{\Omega}, P)
\]

has a bounded inverse if \( k' \leq k, j' \leq j \) and \( k, j \) are integers.

**Proof.** By Lemma 2.2, there exists a solution \( v \in C^{1+\alpha,0} \) to (6.4). The proposition is verified for \( k = 0 \). If \( k \geq 1 \), the assertion that \( v \in C^{k+1+\alpha,0} \) follows from Theorem 6.2 and Lemma 6.3. The last assertion in the proposition follows from \( T_\Omega(\hat{C}^{k+\alpha,0}(\overline{\Omega}, P)) \subseteq \hat{C}^{k+1+\alpha,0}(\overline{\Omega}, P) \) and the open mapping theorem applied to each finite \( k \).

We now apply induction on \( j \). Here we need to use a method from [16], which we have used in Step 2 of the proof of Proposition 3.7. In fact, the proof is valid without any essential changes. We briefly point out the arguments. For \( j = 1 \), the difference quotient \( \delta_\lambda v(\cdot, t) = \frac{v(\cdot, t + \lambda V) - v(\cdot, t)}{\lambda} \) satisfies

\[
\delta_\lambda v(\cdot, t) + T(a(\cdot, t)\partial_\tau \delta_\lambda v(\cdot, t)) = \delta_\lambda b(\cdot, t) - T(\delta_\lambda a(\cdot, t)\partial_\tau v(\cdot, t')) = 0.
\]

Here \( t, t' \) are in the interior of \( P \) and \( t' = t + \lambda V \). For fixed \( t \), we can show that \( \delta_\lambda v(\cdot, t) \) converges to \( \omega(\cdot, t) \) and that \( \omega(\cdot, t) \) is the unique solution to

\[
\omega(\cdot, t) + T(a(\cdot, t)\partial_\tau \omega(\cdot, t)) = \delta_\lambda b(\cdot, t) - T(\delta_\lambda a(\cdot, t)\partial_\tau v(\cdot, t)).
\]

The right-hand side is of class \( \hat{C}^{k+1+\alpha,0} \). Inverting \( I + T(a(\cdot, t)\partial z) \) in the space \( \hat{C}^{k+\alpha,0} \) for each finite \( k \) shows that \( \omega \) is in \( \hat{C}^{k+1+\alpha,0} \), which is \( \partial_\tau v \) satisfying

\[
\partial_\tau v + T(a(\cdot, t)\partial_\tau \partial_\tau v) = \partial_\tau b(\cdot, t) - T(\partial_\tau a(\cdot, t)\partial_\tau v(\cdot, t)).
\]

The equation is the same as (6.4), except for a different \( b \). Inductively, this shows that \( v \) is in \( \hat{C}^{k+1+\alpha,j}(\overline{\Omega}, P) \).

In [3], the Riemann mapping with parameter [3] is proved for simply connected domains in \( C \). We now extend the result to complex structures. The reader is referred to [3] for some elementary properties of \( C^{k+1+\alpha,j}(\overline{\Omega}, [0, 1]) \), where \( C^{k+1+\alpha,j}(\overline{\Omega}, [0, 1]) \) is denoted by \( B^{k+1+\alpha,j}(\overline{\Omega}, [0, 1]) \).
Theorem 6.5. Let $k, j$ be integers or infinity such that $0 \leq j \leq k$ and let $0 < \alpha < 1$. Let $P = \{0, 1\}$. Let $\Gamma(\cdot, t) : \partial \Omega \to \partial \Omega'$ be embeddings for all $t \in P$, which satisfy $\Gamma \in \mathcal{C}^{k+1+\alpha,j} (\partial \Omega, \partial \Omega')$. Let $J'$ be a family of complex structures on $\partial \Omega'$ such that the pull back of $J'$ by $\Gamma(\cdot, t)$ defines a family of complex structures on $\partial \Omega$ of class $\mathcal{C}^{k+\alpha,j} (\partial \Omega, \partial \Omega')$. There exists a family of mappings $R(\cdot, t)$ from $\partial \Omega'$ onto $\partial \Omega$ such that $(z, t) \mapsto R(\Gamma(z, t), t)$ is a mapping of class $\mathcal{C}^{k+1+\alpha,j} (\partial \Omega, \partial \Omega')$ and the push-forward of $J'$ via $R(\cdot, t)$ is the standard complex structure on $\partial \Omega$ for each $t \in P$.

Proof. To localize the problem in the parameter space, we mark three points $a^i, b^i, c^i$ on $\partial \Omega'$ such that $t \mapsto (a^i, b^i, c^i)$ is of class $\mathcal{C}^j$. Let $R(\cdot, t)$ be the Riemann mapping sending $a^i, b^i, c^i$ to $a, b, c$ on the unit circle. We want to show that $R(\cdot, t)$ has the desired regularity for $t$ near a given point $t_0 \in P$.

We first want to find a family of mappings $S(\cdot, t)$ from $\partial \Omega'$ onto $\partial \Omega'$ such that the push-forward of $J'$ agree with the standard complex structure. To see this, we extend $J'$ to a larger simply connected domain $\Omega'$ which contains the closure of $\partial \Omega$. By the uniformization theorem, there exists a family of mappings $S(\cdot, t_0)$ of class $\mathcal{C}^{k+1+\alpha}$ which maps $\Omega'^0$ onto the unit disc or $\mathbb{C}$ such that $S(\cdot, t_0)_* J'^0$ is the standard complex structure. By Kellogg’s theorem, we can find the Riemann mapping sending $S(\cdot, t_0) (\Omega'^0)$ onto the unit disk and match three marked points. For $t$ close to $t_0$, we can find a family of diffeomorphisms of class $\mathcal{C}^{k+1+\alpha,j}$, defined near $\partial \Omega$, which fixes $S(\cdot, t_0) (\Omega'^0)$ pointwise and maps $S(\cdot, t_0) (\partial \Omega')$ onto the unit disk. Therefore, for regularity near $t_0$, we have simplified the problem to the case where $J'^0$ is $J_{st}$ and $\partial \Omega'$ are the unit disk. Then $J'$ are defined by vector fields

$$\partial_z a(z, t) \partial_z$$

with $a(\cdot, t_0) = 0$. Since $a$ is of class $\mathcal{C}^{k+\alpha,j}$, then $|a|_{\alpha,0} < \epsilon_\alpha$ on $\partial \Omega \times \hat{P}$ by choosing a small neighborhood $\hat{P}$ of $t_0$. Here, $\epsilon_\alpha$ is the constant in Proposition 6.4. Let $f(\cdot, t) := u$ be the solution to

$$u + T \partial_z (a(\cdot, t) \partial_z u) = -T \partial_z a(\cdot, t).$$

By Proposition 6.4, $f$ is of class $\mathcal{C}^{k+1+\alpha,j}$. Also $|f|_{1+\alpha,0} \leq C |a|_\alpha < 1$. Therefore, $F(\cdot, t) : z \mapsto z + f(z, t)$ is a family of diffeomorphisms from $\partial \Omega$ onto $\partial \Omega'$ such that $F(\cdot, t)_* J'$ are the standard complex structure. By the Riemann mapping with parameter [3], we conclude that there exists a family of Riemann mappings $R_0(\cdot, t)$ from $D'$ onto the unit disc such that $(z, t) \mapsto R_0(F(z, t), t)$ is of class $\mathcal{C}^{k+1+\alpha,j} (\partial \Omega, \partial \Omega')$. Let $M(\cdot, t)$ be the linear fractional transformation sending

$$(a^i, b^i, c^i) = (R_0(F(a^i, t), t), R_0(F(b^i, t), t), R_0(F(c^i, t), t))$$

to $(a, b, c)$. Since the mapping $t \mapsto (a^i, b^i, c^i)$ is of class $\mathcal{C}^j$, it is easy to verify that $M$ is of class $\mathcal{C}^{k+1+\alpha,j}$ on $\partial \Omega \times \hat{P}$. Then $R(\cdot, t) = M(\cdot, t)$ is of class $\mathcal{C}^{k+1+\alpha,j}$ on $\partial \Omega \times \hat{P}$. \hfill $\square$

From the proof of Lemma 6.3, we also have the following for vector-valued functions.

Lemma 6.6. Let $\Omega \subset \mathbb{C}$ be a bounded domain with $\partial \Omega \in \mathcal{C}^1$. Let $v$ and $b$ be vectors of $n$ continuous functions on $\overline{\Omega}$. Suppose that $v \in \mathcal{C}^1(\Omega)$.

(i) Let $A$ be an $n \times n$ matrix of continuous functions defined on $\overline{\Omega}$. Then $v$ satisfies

$$v + T(b + A \partial_z v) = 0$$

(6.5)
Assume further that $D$ is contained in an open subset $D$ of $\mathbb{C}^n$. Let $A \in \mathcal{C}^1(D)$ be an $n \times n$ matrix. Then $v$ satisfies

\begin{equation}
\partial_tv + b + A\partial_zv = 0. \tag{6.6}
\end{equation}

(ii) Assume further that $v(\bar{\Omega})$ is contained in an open subset $D$ of $\mathbb{C}^n$. Let $A \in \mathcal{C}^1(D)$ be an $n \times n$ matrix. Then $v$ satisfies

\begin{equation}
v + T(b + A(v)\overline{\partial_z}v) = 0 \tag{6.7}
\end{equation}

if and only if $v$ satisfies (6.3) and

\begin{equation}
\partial_tv + b + A(v)\overline{\partial_z}v = 0. \tag{6.8}
\end{equation}

Here, the equations (6.3), (6.5)-(6.8) hold on $\Omega$.

We now use the proof of Theorem 6.2 to study a problem in different directions.

**Proposition 6.7.** Let $k$ be an integer and let $0 < \alpha < 1$. Let $\gamma$ be an embedded curve in $\mathbb{C}$ of class $C^{k+1+\alpha}$. Let $\Omega_1, \Omega_2$ be disjoint two open subsets of $\mathbb{C}$ such that both $\partial \Omega_1, \partial \Omega_2$ contain $\gamma$ as a relatively open subset. Assume that $a_t \in C^{k+\alpha}(\Omega_t \cup \gamma)$ satisfies $|a_t|_{L^\infty} < 1$ on $\Omega_t \cup \gamma$. Let $E$ be an embedded $C^1$ curve in $\mathbb{D}$ such that $\mathbb{D} \setminus E$ is open in $\mathbb{C}$ and has exactly two connected components $\Omega_1, \Omega_2$. Assume that $u$ is a continuous map from $\mathbb{D}$ into $\Omega_1 \cup \gamma \cup \Omega_2$ such that $u(\cdot, \omega_t) \rightarrow \Omega_t$ are $J$-holomorphic with respect to $\partial_{\mathbb{D}} + a_t \partial_z$. Then $E$ is a curve of class $C^{k+1+\alpha}$.

**Proof.** The proof is a slight modification of the proof of Theorem 6.2. The problem is local. Fix $z_0 \in E$ and let $p = u(z_0)$. We may assume that near $p$, $\gamma$ is contained in the real axis and $\Omega_1, \Omega_2$ are contained in the lower and upper half planes. Applying a local change of coordinates $\varphi_t$ which is of class $C^{k+1+\alpha}$ on $\Omega_t \cup \gamma$ and fixes $\gamma$ pointwise, we may assume that $a_t = O(|y|^{k+\alpha})$. Define $a := a_t$ on $\Omega_t \cup \gamma$. Then $X := \partial_{\mathbb{D}} + a \partial_z$ is of class $C^{k+\alpha}$ on $\Omega_t \cup \gamma$. Near $p \in \gamma$, we apply a diffeomorphism $\phi$ of class $C^{k+1+\alpha}$ which transforms $x$ into $\partial_x$. Let $g = \phi \circ \varphi_t \circ u$ on $\Omega_t \cup E$, which is holomorphic away from $E$. Since $g$ is continuous and $E$ is an embedded $C^1$ curve, then $g$ is holomorphic at $z_0$. It is easy to verify that $g$ is biholomorphic near $z_0$. Consequently, $E$ is of class $C^{k+1+\alpha}$ near $z_0$. \hfill \square

However, the above result fails in higher dimensions.

**Example 6.8.** Let $E$ be an embedded $C^1$ curve connecting $i, -i$ and dividing $\mathbb{D}$ into two components $\omega_1, \omega_2$. Let $\lambda$ be a $C^\infty$ function on $\mathbb{D}$ which is positive on $\omega_1$ and negative on $\omega_2$. The existence of such a function is trivial, by taking it vanishing to infinity order along $E$. We use the standard complex structure on $\mathbb{D} \times \mathbb{C} = \{ \text{Im} w < \lambda(z) \} \cup \{ \text{Im} w = \lambda(z) \} \cup \{ \text{Im} w > \lambda(z) \}$. Let $u(z) := (z, 0)$. Then $u(\omega_t) \rightarrow \Omega_t$ are holomorphic, $\gamma = \{ \text{Im} w = \lambda(z) \}$ is $C^\infty$, $u(\mathbb{D}) = \mathbb{D} \times \{ 0 \}$, but $E$ needs not to be $C^\infty$.

We would like to mention that our main result fails for harmonic functions. For instance, we take a continuous function $f$ on $[-1, 1]$ and then extend continuously to $\partial \mathbb{D}$. Extend $f$ harmonically by solving two Dirichlet problems on $\mathbb{D}^+$ and $\mathbb{D}^-$. Then $f$ is not $C^\infty$ on $\overline{\mathbb{D}}^+$ in general. One sees a similar result for the Neumann problem. Let $\Omega$ be a bounded domain in $\mathbb{C}$ with $\partial \Omega \in C^\infty$. Suppose that $f$ is continuous on $\partial \Omega$ and $dt$ is the arc-length element.
on $\partial \Omega$. Then $W_f(z) = \frac{1}{\pi} \int_{\partial \Omega} f(t) \log |\gamma(t) - z| \, dt$ is harmonic on $\mathbb{C} \setminus \partial \Omega$ and continuous on $\mathbb{C}$. However,

$$\partial_n(s)W_f = f(s) + \frac{1}{\pi} \int_{\partial \Omega} f(t) \partial_s \arg(\gamma(t) - \gamma(s)) \, dt,$$

$$\partial_{-n}(s)W_f = f(s) - \frac{1}{\pi} \int_{\partial \Omega} f(t) \partial_s \arg(\gamma(t) - \gamma(s)) \, dt.$$ 

Here $n(s)$ is the unit outer normal vector of $\partial \Omega$. In particular, if $f$ is not smooth, then $W_f$ cannot be smooth simultaneously on $\Omega$ and $\mathbb{C} \setminus \partial \Omega$. It is interesting that if $W_f \in C^1(\mathbb{C})$, then $f$ and $W_f$ must be zero.

We conclude the paper by mentioning two open problems. Recall that Theorem 6.2 is essential to the proof of Theorem 1.2. Both theorems deal with the case where $f$ is a function. If $f$ is vector-valued, we have the following open problem.

**Problem A.** Let $m \geq 2$ be an integer and let $0 < \alpha < 1$. Let $\Omega$ be a bounded domain in $\mathbb{C}$ with $C^\infty$ boundary. Let $a \in C^\infty(\overline{\Omega})$ be an $m \times m$ matrix with a sufficiently small $C^\alpha$ norm on $\overline{\Omega}$. Does $I + T_\Omega a \partial_z : [C^{k+\alpha}(\overline{\Omega})]^m \to [C^{k+\alpha}(\overline{\Omega})]^m$ have a bounded inverse for all positive integer $k$?

The following boundary regularity problem arises from the proof of Proposition 3.7 on $J$-holomorphic curves.

**Problem B.** Let $\Omega$ be a bounded domain in $\mathbb{C}$ with $C^\infty$ boundary. Let $D$ be a domain in $\mathbb{C}^n$ with $n \geq 1$. Let $A$ be an $n \times n$ matrix of $C^\infty$ functions on $D$. Suppose that the operator norm $\|A(w)\|$ is less than 1 for each $w \in D$. Let $u: \overline{\Omega} \to D$ be a $C^1$ map such that

$$(6.9) \quad u + T_\Omega ((\overline{\partial_z} u) A(u)) \in C^\infty(\overline{\Omega}).$$

Is $u \in C^\infty(\overline{\Omega})$?
