Homotopy theory with ∗-categories

Ulrich Bunke*

October 3, 2018

Abstract
We construct model category structures on various types of (marked) ∗-categories. These structures are used to present the infinity categories of (marked) ∗-categories obtained by inverting (marked) unitary equivalences. We use this presentation to explicitly calculate the ∞-categorical $G$-fixed points and $G$-orbits for $G$-equivariant (marked) ∗-categories.

1 Introduction

1.1 Model categories

If $C$ is a category and $W$ is a set of morphisms in $C$, then one can consider the $\infty$-category $C[W^{-1}]$. If the relative category $(C, W)$ extends to a simplicial model category in which all objects are cofibrant, then we have an equivalence between $C[W^{-1}]$ and the nerve $N(C^{cf})$ of the simplicial category of cofibrant/fibrant objects of $C$. This explicit description of $C[W^{-1}]$ is sometimes very helpful in order to calculate mapping spaces in $C[W^{-1}]$, or in order to identify limits or colimits of diagrams in $C[W^{-1}]$.

In this note $C$ is a category of $\ast$-categories. A $\ast$-category is a category with an involution $\ast$ fixing the objects. In such a category one can talk about unitary morphisms. Furthermore, one can talk about unitary transformations between functors between $\ast$-categories and therefore about unitary equivalences between $\ast$-categories. One natural choice for $W$ is the set of unitary equivalences.

There are cases where one is interested in $\ast$-categories with a distinguished subset of the unitary morphisms called marked morphisms. We call such a $\ast$-category a marked $\ast$-category. We can then consider the category $\mathcal{C}^+$ of such marked $\ast$-categories with functors preserving the marked morphisms. Moreover, we can talk about marked isomorphisms between functors between marked $\ast$-categories. In this case we let $W$ be the subset of morphisms which are invertible up marked isomorphism.

In the present paper we consider the following categories $C$ of $\ast$-categories and their marked versions $\mathcal{C}^+$.

1. $\ast$-categories $\ast\text{Cat}^+$: categories $A$ with an involution $\ast : A \to A^\text{op}$.

2. $\mathbb{C}$-linear $\ast$-categories $\ast\text{Cat}^+$: $\ast$-categories enriched over $\mathbb{C}$-vector spaces with an anti-linear involution.

---

\[1\text{In order to fix size issues we use three Grothendieck universes } U \subseteq V \subseteq W. \text{ The objects of } \mathcal{C} \text{ will be categories in } V \text{ which are locally } U\text{-small. The category } \mathcal{C} \text{ itself belongs to } W \text{ and is locally } V\text{-small.}\]
3. pre-$C^*$-categories $C^*_\text{pre}\text{Cat}_1$: $\mathbb{C}$-linear $\ast$-categories which admit a maximal $C^*$-completion.

4. $C^*$-categories $C^*\text{Cat}_1$: pre-$C^*$-categories whose $\text{Hom}$-vector spaces are complete in the maximal norm.

If $A$ belongs to one of these examples, then a unitary morphism in $A$ is a morphism $u$ whose inverse is given by $u^\ast$. A marking on $A$ is a choice of a subset of unitary morphisms containing all identities which is closed under composition and the $\ast$-operation. A morphism between marked categories must send marked morphisms to marked morphisms.

We write $\ast\text{Cat}_1^+$, $\ast\text{Cat}_1$, $C^*_\text{pre}\text{Cat}_1^+$ and $C^*\text{Cat}_1^+$ for the categories of marked objects in these examples. The subscript 1 indicates that we consider them as 1-categories.

The case of $C^*$-categories has been considered previously in $[\text{Del10}]$. Many arguments in the present paper are modifications of the arguments given in $[\text{Del10}]$ in order to be applicable in the other cases.

**Remark 1.1.** We consider $\mathbb{C}$-linear $\ast$-categories since this case fits with the $C^*$-examples. The assertions about the model category on $\ast\text{Cat}_1$ and the version of Theorem 13.6 extends to the case where $\mathbb{C}$ is replaced by an arbitrary ring with involution.

An analogous theory for marked preadditive and additive categories will appear in $[\text{BEKW}]$. 

We now state the main result in detail. Let $\mathcal{C}$ belong to the list of categories

\[
\{ \ast\text{Cat}_1, \ast\text{Cat}_1, C^*_\text{pre}\text{Cat}_1, C^*\text{Cat}_1, \ast\text{Cat}_1^+, \ast\text{Cat}_1^+, C^*_\text{pre}\text{Cat}_1^+, C^*\text{Cat}_1^+ \} \tag{1.1}
\]

**Definition 1.2.**

1. A weak equivalence in $\mathcal{C}$ is a (marked) unitary equivalence.

2. A cofibration is a morphism in $\mathcal{C}$ which is injective on objects.

3. A fibration is a morphism in $\mathcal{C}$ which has the right-lifting property with respect to trivial cofibrations.

In condition 1 the word marked only applies to the four marked versions. For the simplicial structure we refer to Definition 6.19 below since its introduction needs more notation. For the definition of the notion of a cofibrantly generated model category we refer to $[\text{Hov99}, \text{Def. 2.1.17}]$.

**Theorem 1.3.** The structures described in Definition 1.2 and Definition 6.19 equip $\mathcal{C}$ with a simplicial model category structure.

If $\mathcal{C}$ belongs to the list

\[
\{ \ast\text{Cat}_1, \ast\text{Cat}_1, C^*\text{Cat}_1, \ast\text{Cat}_1^+, \ast\text{Cat}_1^+, C^*\text{Cat}_1^+ \},
\]

then the model category structure is cofibrantly generated and the underlying category is locally presentable.
Remark 1.4. In the case of $\mathcal{C} = C^\star \text{Cat}_1$ a proof of this theorem (except the local presentability) was given in [Del10].

Remark 1.5. A cofibrantly generated simplicial model category which is in addition locally presentable is called combinatorial [Dug01], [Lur09, A.2.6.1]. Hence $\ast \text{Cat}_1$, $\ast \text{Cat}_1^+$, $\ast \text{preCat}_1$, $\ast \text{preCat}_1^+$, $C^\ast \text{Cat}_1$ and $C^\ast \text{preCat}_1^+$ have combinatorial simplicial model category structures.

At the moment we do not know whether $C^\ast \text{preCat}_1$ or $C^\ast \text{preCat}_1^+$ are cofibrantly generated or locally presentable.

Remark 1.6. The existence and combinatoriality of this model category structure on $\ast \text{Cat}_1$ has been previously asserted by Joyal in [Joy10].

All categories $\mathcal{C}$ in the list (1.1) have a notion of (marked) unitary equivalences. Inverting the (marked) unitary equivalences $W_\mathcal{C}$ in the realm of $(\infty, 1)$ (short $\infty$)-categories we obtain the list

$$\{\ast \text{Cat}, \ast \text{Cat}_1, C^\ast \text{preCat}_1, C^\ast \text{preCat}_1^+, \ast \text{preCat}_1, \ast \text{preCat}_1^+, C^\ast \text{Cat}_1, C^\ast \text{Cat}_1^+\}$$

of $\infty$-categories $\mathcal{C}_\infty := \mathcal{C}[W_\mathcal{C}^{-1}]$.

Remark 1.7. More precisely, we model $\infty$-categories as quasi-categories. Our basic references are [Lur09] and [Cis]. We identify categories with $\infty$-categories using the nerve functor. In this case we will omit the nerve from the notation. If $(\mathcal{C}, W)$ is a relative category, then there exists a localization functor

$$\ell : \mathcal{C} \rightarrow \mathcal{C}_\infty := \mathcal{C}[W^{-1}],$$

see [Lur17] Def. 1.3.4.1, [Cis 7.1.2]. It is characterized essentially uniquely by the universal property that

$$\ell^\ast : \text{Fun}(\mathcal{C}_\infty, \mathcal{D}) \rightarrow \text{Fun}_W(\mathcal{C}, \mathcal{D})$$

is an equivalence for every $\infty$-category $\mathcal{D}$, where $\text{Fun}_W$ denotes the full subcategory of functors sending the morphisms in $W$ to equivalences.

Remark 1.8. The model category structure on $\mathcal{C}$ asserted in Theorem 1.3 provides a model for $\mathcal{C}_\infty$.

In general, let $\mathcal{C}$ be a simplicial model category with weak equivalences $W$ and set $\mathcal{C}_\infty := \mathcal{C}[W^{-1}]$. We consider the full subcategory $\mathcal{C}^{cf}$ of $\mathcal{C}$ of cofibrant/fibrant objects which is enriched in Kan complexes. If either all objects of $\mathcal{C}$ are cofibrant, or $\mathcal{C}$ admits functorial factorizations (e.g., if $\mathcal{C}$ is combinatorial), then by [DK80a], or [Lur17, Def. 1.3.4.15, 2]

2I thank Philip Hackney for pointing this out.

3In [Hin16] this localization is called the Dwyer-Kan localization, since it has been first considered by [DK80b] in the context of simplicial categories, and in order to distinguish it from the localizations considered in the book [Lur09] which are versions of Bousfield localizations.

4a more precise notation would be $\mathcal{N}(\mathcal{C}) \rightarrow \mathcal{N}(\mathcal{C})[W^{-1}]$
Thm. 1.3.4.20] (and in addition [Lur17, Rem. 1.3.4.16] in the second case) we have an equivalence
\[ C_\infty \simeq \mathbb{N}(C^{cf}) , \]
where \( \mathbb{N}(C^{cf}) \) is the nerve [Lur09, Def. 1.1.5.5] of the fibrant simplicial category \( C^{cf} \). In particular, for \( A, B \) in \( C^{cf} \) we have an equivalence of spaces
\[ \text{Map}_{C_\infty}(\ell(A), \ell(B)) \simeq \ell_{sSet}(\text{Map}_C(A, B)) , \]
(1.3)
where \( \text{Map}_C(A, B) \) is the simplicial mapping set and \( \ell_{sSet} : sSet \to sSet[W^{-1}] \simeq \text{Spc} \) is the usual localization of the category of simplicial sets at the weak homotopy equivalences. In order to see this we could use [DK80a, 1.1.(iv)] in order relate \( \ell_{sSet}(\text{Map}_C(A, B)) \) with \( \ell_{sSet}(\text{Map}_{L^H(C, W)}(A, B)) \), where \( L^H \) denotes the hammock localization, and [Hin16, Prop. 1.2.1] in order to relate \( L^H(C, W) \) with the \( \infty \)-categorical localization \( C_\infty \).

Note that for the equivalence (1.3) it actually suffices to assume that \( A \) is cofibrant and \( B \) is fibrant.

By [Lur09, A.3.7.6] the \( \infty \)-category, associated as described in Remark 1.8, to a simplicial and combinatorial model category is presentable. Consequently Theorem 1.3 implies:

**Corollary 1.9.** The \( \infty \)-categories \( \ast \text{Cat} \), \( \ast \text{Cat}^+ \), \( \ast \text{C Cat} \), \( \ast \text{C Cat}^+ \), \( C^* \text{Cat} \) and \( C^* \text{Cat}^+ \) are presentable.

### 1.2 Homotopy fixed points and orbits

Let \( G \) be a group. The category of \( G \)-objects in a category \( C \) is defined as the functor category \( \text{Fun}(BG, C) \). Here \( BG \) is the category with one object \( pt \) and \( \text{Hom}_{BG}(pt, pt) = G \) such that the composition is given by the multiplication in \( G \).

We now assume that the category \( C \) belongs to the list
\[ \{ \ast \text{Cat}_1, \ast \text{C Cat}_1, C^*\text{pre Cat}_1, C^*\text{Cat}_1, C^*\text{Cat}_1^+, \ast \text{C Cat}_1^+, C^*\text{pre Cat}_1^+, C^*\text{Cat}_1^+ \} . \]

By \( \ell : C \to C_\infty \) we denote the localization [1.2] which inverts the (marked) unitary equivalences. Furthermore, we let
\[ \ell_{BG} : \text{Fun}(BG, C) \to \text{Fun}(BG, C_\infty) \]
denote the functor given by post-composition with \( \ell \). We consider an object \( A \) with an action of \( G \), i.e., an object of \( \text{Fun}(BG, C) \). One of the purposes of the present paper is to calculate the object
\[ \lim_{BG} \ell_{BG}(A) . \]

Calculation of this limit amounts more precisely to provide an object \( B \) of \( C \) and an equivalence
\[ \lim_{BG} \ell_{BG}(A) \simeq \ell(B) . \]
Such an object \( B \) will be defined in Definition 12.1 where it is denoted by \( \hat{A}^G \). The construction of \( \hat{A}^G \) as such is not very surprising and reflects the construction of a two-categorical limit. In Theorem 13.6 we verify that it indeed represents the \( \infty \)-categorical limit, i.e., that we have an equivalence

\[
\lim_{BG} \ell_{BG}(A) \simeq \ell(\hat{A}^G).
\]

In order to approach the task of the calculation of the \( \infty \)-categorical limit of the \( G \)-object \( \ell_{BG}(A) \), using Theorem 1.3 we present the \( \infty \)-category \( \text{Fun}(BG, C_\infty) \) in terms of an injective model category structure on \( \text{Fun}(BG, C) \), see Remark 1.8. We then observe that

\[
\lim_{BG} R(A) \cong \hat{A}^G,
\]

where \( R : \text{Fun}(BG, C) \to \text{Fun}(BG, C) \) is an explicitly given fibrant replacement functor. In model categorical language one would say that \( \hat{A}^G \) represents the homotopy \( G \)-invariants in \( A \). We then use general results from \( \infty \)-category theory in order to justify that these homotopy invariants indeed represent the limit in the \( \infty \)-categorical sense.

We are interested in these calculations of homotopy fixed points since they appear in the investigation of equivariant coarse homology theories. The details of this application will be explained in Section 14 which also provides the motivation for considering markings.

We now turn to \( G \)-orbits. We assume that \( C \) belongs to the list

\[
\{^*\text{Cat}_1, ^*_{c}\text{Cat}_1, C^*\text{Cat}_1, ^*\text{Cat}_1^+, ^*_{c}\text{Cat}_1^+, C^*\text{Cat}_1^+\}.
\]

If \( G \) is a group and \( A \) is an object of \( C \), then by \( A \) we denote the object of \( \text{Fun}(BG, C) \) given by \( A \) with the trivial action of \( G \). We are interested in the calculation of the colimit

\[
\lim_{BG} \ell_{BG}(A)
\]

in \( C_\infty \). This again amounts to provide an object \( B \) of \( C \) and an equivalence

\[
\lim_{BG} \ell_{BG}(A) \simeq \ell(B).
\]

In Section 6 we construct a bifunctor

\[
C \times \text{Grpd}_1 \to C, \quad (A, G) \mapsto A^+_G.
\]

Our main result is Theorem 15.6 which asserts that

\[
\lim_{BG} \ell_{BG}(A) \simeq \ell(A^+_BG).
\]

The main point here is again that we calculate a colimit in the infinity-categorical sense. To this end, using Theorem 1.3 we present the \( \infty \)-category \( \text{Fun}(BG, C_\infty) \) in terms of a projective model category structure on \( \text{Fun}(BG, C) \). Then we show that

\[
\lim_{BG} L(A) \cong A^+_BG,
\]
where $L$ is an explicit cofibrant replacement functor. In model categorical language one would say that $A \sharp BG$ represents the homotopy $G$-orbits of $A$. We then again use general results from $\infty$-category theory in order to justify that these homotopy orbits represent the colimit in the $\infty$-categorical sense.

The calculation of $G$-orbits will be applied in order to identify the values of an induction functor (Definition 15.10)

$$J^G : C \xrightarrow{(-)} \text{Fun}(BG, C) \xrightarrow{\ell_{BG}} \text{Fun}(BG, C_{\infty}) \xrightarrow{LKan} \text{Fun}(\text{Orb}(G), C_{\infty}),$$

where $LKan$ is the left-Kan extension functor associated to the canonical inclusion $BG \to \text{Orb}(G)$. By Proposition [15.11] for a subgroup $H$ of $G$, we get an equivalence

$$J^G(C)(H \backslash G) \simeq \ell(C\sharp BH).$$

This result will be applied in order to identify the coefficients of certain equivariant homology theories.

Acknowledgement: The author was supported by the SFB 1085 Higher Invariants funded by the Deutsche Forschungsgemeinschaft DFG. He thanks Markus Land for valuable discussions and pointing out the reference [Del10]. He profited from discussions with Denis-Charles Cisinski about injective model category structures. He furthermore thanks Dmitri Pavlov for convincing him that Proposition [11.7] should be true. Finally he thanks Christoph Winges for pointing out a mistake in an earlier version whose correction led to the consideration of marked categories.

2 (Marked) $\ast$-categories and linear versions

In this section we introduce the notion of a $\ast$-category and various $\mathbb{C}$-linear versions.

**Definition 2.1.** A $\ast$-category $(A, \ast)$ is a small category $A$ with an involution $\ast : A \to A^{\text{op}}$ which fixes the objects. A morphism between $\ast$-categories is a functor between the underlying categories which preserves the involutions.

We let $\ast\text{Cat}_1$ denote the category of $\ast$-categories and morphisms between $\ast$-categories. Usually we will just use the notation $A$ instead of $(A, \ast)$.

If $f$ is a morphism in a $\ast$-category, then we will write $f^\ast$ for the image of $f$ under the involution $\ast$.

**Example 2.2.** Let $G$ be a group. Then the category $BG$ with morphisms $\text{Hom}_{BG}(pt, pt) = G$ can be turned into a $\ast$-category by setting

$$g^\ast := g^{-1}.$$

More generally, if $G$ is any groupoid, then we can consider $G$ as a $\ast$-category with the $\ast$-operation given by $g^\ast := g^{-1}$.
Definition 2.3. A \( \mathbb{C} \)-linear \(*\)-category is a \(*\)-category \( \mathbf{A} \) which is in addition enriched over \( \mathbb{C} \)-vector spaces such that and for all objects \( a, a' \) of \( \mathbf{A} \) the map
\[
* : \text{Hom}_\mathbf{A}(a, a') \to \text{Hom}_\mathbf{A}(a', a)
\]
is anti-linear. A morphism between \( \mathbb{C} \)-linear \(*\)-categories is a morphism between \(*\)-categories which is also a functor between \( \mathbb{C} \)-vector space enriched categories.

We let \(*_\mathbb{C}\text{-Cat}_1\) denote the category of \( \mathbb{C} \)-linear \(*\)-categories and morphisms between \( \mathbb{C} \)-linear \(*\)-categories.

Remark 2.4. Note that in a \( \mathbb{C} \)-linear \(*\)-category \( \mathbf{A} \) for any two objects \( a, a' \) in \( \mathbf{A} \) the morphism space \( \text{Hom}_\mathbf{A}(a, a') \) is not empty. But it may be the zero vector space. This in particular applies to the endomorphisms \( \text{End}_\mathbf{A}(a) \). If this is the zero vector space, then we have \( \text{id}_a = 0 \). In this case the object \( a \) will be called a zero object. The morphism spaces from and to zero objects are zero vector spaces.

Example 2.5. An algebra \( A \) over \( \mathbb{C} \) with an anti-linear involution can be considered as a \(*\)-category \( \mathbf{A} \) with one object \( pt \) and the \( \mathbb{C} \)-vector space of endomorphisms \( \text{Hom}_\mathbf{A}(pt, pt) := A \). The composition is given by the algebra multiplication, and the involution on \( A \) induces the \(*\)-functor.

An important example is the underlying algebra with involution of a \( C^* \)-algebra.

We will also encounter the \( \mathbb{C} \)-linear \(*\)-category \( \Delta^0_{\mathbb{C}\text{-Cat}_1} \) associated to the algebra \( \mathbb{C} \). The notation indicates that this \( \mathbb{C} \)-linear \(*\)-category is the object classifier (see Definition 4.2) in \(*_\mathbb{C}\text{-Cat}_1\).

A particular example is the zero algebra 0 and the associated \( \mathbb{C} \)-linear \(*\)-category 0. The unique object in this \( \mathbb{C} \)-linear \(*\)-category is a zero object.

In the following we consider the zero algebra as a \( C^* \)-algebra. Let \( \mathbf{A} \) be a \( \mathbb{C} \)-linear \(*\)-category.

Definition 2.6. A representation of \( \mathbf{A} \) in a \( C^* \)-algebra \( B \) is a map \( \rho : \text{Mor}(\mathbf{A}) \to B \) with the following properties:

1. For every two objects \( a, a' \) of \( \mathbf{A} \) the restriction of \( \rho \) to the subset \( \text{Hom}_\mathbf{A}(a, a') \) of \( \text{Mor}(\mathbf{A}) \) is \( \mathbb{C} \)-linear.

2. \( \rho(f \circ g) = \rho(f) \rho(g) \) for all pairs of composeable morphisms \( f, g \) in \( \text{Mor}(\mathbf{A}) \)

3. \( \rho(f^*) = \rho(f)^* \) for all \( f \) in \( \text{Mor}(\mathbf{A}) \)

Remark 2.7. One could say that a representation \( \rho \) as in Definition 2.6 is a possibly non-unital morphism of \( \mathbb{C} \)-linear \(*\)-categories \( \mathbf{A} \to \mathbf{B} \), where \( \mathbf{B} \) is the (possibly non-unital) \( \mathbb{C} \)-linear \(*\)-category associated to the \( C^* \)-algebra \( B \) as in Example 2.5. Since we do not want to talk about non-unital morphisms we avoid to use this interpretation.
Example 2.8. We consider the commutative \( \mathbb{C} \)-algebra
\[
A := \mathbb{C}[x]((x - r)^{-1})_{r \in \mathbb{R}}
\]
with \( \ast \)-operation given by \( x^* = x \) as a \( \mathbb{C} \)-linear \( \ast \)-category \( A \). Assume that \( \rho : A \to B \) is a representation in a non-zero \( C^* \)-algebra. Then \( \rho(1) \) is a non-zero selfadjoint idempotent which commutes with \( \rho(a) \) for all elements \( a \) of \( A \). We can form the non-zero \( C^* \)-algebra
\[
B' := \rho(1)B\rho(1)
\]
with unit \( 1' := \rho(1) \) and obtain a unital representation \( \rho' : A \to B' \) given by \( \rho'(a) := \rho(1)\rho(a)\rho(1) \). Then \( \rho'(x) \) would be a selfadjoint element in \( B' \) with empty spectrum. This is impossible. Therefore \( A \) does not admit any representation in a non-zero \( C^* \)-algebra. \( \square \)

Let \( A \) be a \( \mathbb{C} \)-linear \( \ast \)-category and \( f \) be a morphism in \( A \).

Definition 2.9. We define the maximal norm of the morphism \( f \) by
\[
\|f\|_{\text{max}} := \sup_{\rho} \|\rho(f)\|_B,
\]
where the supremum is taken over all representations of \( A \) in \( C^* \)-algebras \( B \) and \( \|\cdot\|_B \) denotes the norm of \( B \).

Apriory we have \( \|f\|_{\text{max}} \in [-\infty, \infty] \). We note the following facts about the maximal norm on a \( \mathbb{C} \)-linear \( \ast \)-category \( A \):

1. For every morphism \( f \) of \( A \) we have \( \|f\|_{\text{max}} \geq 0 \) since we always have the representation into the zero algebra.
2. For every two composable morphisms \( f \) and \( g \) of \( A \) we have the inequality \( \|g \circ f\|_{\text{max}} \leq \|g\|_{\text{max}} \|f\|_{\text{max}} \).
3. For every morphism \( f \) of \( A \) we have the \( C^* \)-equality \( \|f\|^2_{\text{max}} = \|f^*f\|_{\text{max}} \).
4. For every pair \( f, g \) of parallel morphisms in \( A \) we have the \( C^* \)-inequality \( \|f\|^2_{\text{max}} \leq \|f^* \circ f + g^* \circ g\|_{\text{max}} \).

The last three properties hold true since they are satisfied in every representation of \( A \).

The maximal norm is preserved by unitary equivalences between \( \mathbb{C} \)-linear \( \ast \)-categories, see Lemma 5.5 below.

Definition 2.10. A pre-\( C^* \)-category is a \( \mathbb{C} \)-linear \( \ast \)-category in which every morphism has a finite norm.

We let \( C^*_\text{pre}\mathbf{Cat}_1 \) denote the full subcategory of \( \ast_\mathbb{C}\mathbf{Cat}_1 \) of pre-\( C^* \)-categories.

Example 2.11. If \( A \) comes from a \( C^* \)-algebra \( A \) with \( \|\cdot\|_A \) as in Example 2.5 then the representations of \( A \) in \( C^* \)-algebras \( B \) correspond to \( C^* \)-algebra homomorphisms \( A \to B \). Since morphisms between \( C^* \)-algebras are norm-bounded by 1 we have the equality
\[
\|\cdot\|_{\text{max}} = \|\cdot\|_A.
\]
Therefore \( A \) is a pre-\( C^* \)-category. \( \square \)
Example 2.12. Let $A := \mathbb{C}[x]$ be the polynomial ring with the $*$-operation given by complex conjugation. We consider $A$ as a $\mathbb{C}$-linear $*$-category $\mathbf{A}$. Every real number $\mu$ provides a $*$-homomorphism $\rho_\mu : A \to \mathbb{C}$ given by evaluation of the polynomials at $\mu$. We have $\|\rho_\mu(x)\| = |\mu|$. Hence $\|x\|_{\text{max}} = \infty$. Consequently, the $\mathbb{C}$-linear $*$-category $\mathbf{A}$ is not a pre-$C^*$-category.

If $K$ is a compact subset of $\mathbb{R}$, then we define for $f$ in $\mathbb{C}[x]$

$$\|f\|_K := \sup_{k \in K} \rho_k(f).$$

If we take the closure of $\mathbb{C}[x]$ with respect to this norm, then we get the $C^*$-algebra of continuous functions $C(K)$ on $K$. This shows that a $\mathbb{C}$-linear $*$-category which is not a pre-$C^*$-category still may have many non-trivial $C^*$-closures.

Example 2.13. We consider the $\mathbb{C}$-linear $*$-category $\mathbf{A}$ from Example 2.8. Since it has no non-trivial $*$-representations the maximal norm on it is trivial. Consequently it is a pre-$C^*$-category.

Definition 2.14. A $C^*$-category is a pre-$C^*$-category in which for every pair of objects the morphism vector space is a Banach space with respect to the norm $\|\cdot\|_{\text{max}}$.

We let $C^*\text{Cat}_1$ denote the full subcategory of $C^*_\text{preCat}_1$ of $C^*$-categories.

Remark 2.15. According to the usual definition a $C^*$-category $\mathbf{C}$ is a $\mathbb{C}$-linear $*$-category in which the morphism spaces are equipped with norms such that:

1. The morphism spaces are complete.
2. For composable morphisms we have $\|f \circ g\| \leq \|g\| \|f\|$.
3. The $C^*$-identity $\|f^* \circ f\| = \|f\|^2$ holds true for every morphism $f$.
4. For every pair $f, g$ of parallel morphisms the $C^*$-inequality $\|f\|^2 \leq \|f^*f + g^*g\|$ holds true.

We claim that the maximal norm on such a category considered as a $\mathbb{C}$-linear $*$-category coincides with the given norm. Since every representation of $C^*$-categories (in the usual definition) is norm-decreasing we conclude that the maximal norm on $\mathbf{C}$ is smaller than the given norm.

In order to show equality we form the $C^*$-algebra

$$A(\mathbf{C}) := \bigoplus_{c, c' \in \mathbf{C}} \text{Hom}_\mathbf{C}(c, c')$$

(the sum is taken in the category of Banach spaces and involves completion) with the composition given by matrix multiplication and the obvious $*$-operation. Let $\rho : \mathbf{C} \to A(\mathbf{C})$ denote the canonical representation. Then $\|f\| = \|\rho(f)\|_{A(\mathbf{C})}$.

This implies that our definition of a $C^*$-category coincides with the classical one. Furthermore, being a $C^*$-category is just a property of a $\mathbb{C}$-linear $*$-category and not an additional structure.
We have a chain of functors

\[ C^*\text{Cat}_1 \subseteq C^{\text{pre}}_\ast \text{Cat}_1 \subseteq *\ contents \to *\text{Cat}_1 \to \text{Cat}_1, \quad (2.1) \]

where the first two are fully faithful.

**Remark 2.16.** The categories \( C^*\text{Cat}_1, *\text{Cat}_1, *\text{Cat}_1, \) and \( \text{Cat} \) are closed under taking full subcategories. For \( C^*\text{Cat}_1 \) this follows from Remark [2.15] and for the other three examples this is clear.

For \( C^{\text{pre}}_\ast \text{Cat}_1 \), going to a full subcategory may increase the maximal norm since there might be functors from the subcategory to \( C^* \)-algebras which do not extend to the whole category. We can not exclude that it becomes infinite. \qedsymbol

Let \( C \) be a member of the list

\[ \{ *\text{Cat}_1, C^*\text{Cat}_1, *\text{Cat}_1, C^*\text{Cat}_1 \} \quad (2.2) \]

and \( A \) be an object of \( C \).

Let \( a, a' \) be objects of \( A \), and \( u \) be a morphism in \( \text{Hom}_A(a, a') \).

**Definition 2.17.** The morphism \( u \) is called unitary if \( u^*u = \text{id}_a \) and \( uu^* = \text{id}_{a'} \).

Note that the zero morphism between two zero objects is unitary.

**Definition 2.18.** A marking on \( A \) is a choice of a subset of the unitary morphisms containing all identities which is preserved by the involution * and closed under composition.

We can talk about marked objects in \( C \). A marked object in \( C \) has an underlying object in \( C \) obtained by forgetting the marking.

**Definition 2.19.** A morphism between two marked objects in \( C \) is a morphism between the underlying objects in \( C \) which sends marked morphisms to marked morphisms.

In this way we obtain categories \( C^*\text{Cat}_1^+, *\text{Cat}_1^+, *\text{Cat}_1^+, \) or \( \text{Cat}_1^+ \) of marked objects and morphisms between marked objects.

**Remark 2.20.** Let \( C \) be in the list \( \{ C^*\text{Cat}_1^+, *\text{Cat}_1^+, *\text{Cat}_1^+, \text{Cat}_1^+ \} \) and \( A \) be an object of \( C \). Then we can consider the subcategory \( A^+ \) of \( A \) with the same objects as \( A \) and marked morphisms. Note that \( A^+ \) is a groupoid. A morphism \( f : A \to B \) in \( C \) induces a morphism of categories \( f^+ : A^+ \to B^+ \).

**Example 2.21.** Let \( C \) be in the list \( \{ *\text{Cat}_1, C^*\text{Cat}_1, *\text{Cat}_1, C^*\text{Cat}_1 \} \) and \( A \) be an object of \( C \). Then we can consider the marked category \( \text{mi}(A) \) in \( C^+ \) whose marked morphisms are exactly the identities. We can also consider the marked category \( \text{ma}(A) \) in \( C^+ \) whose marked morphisms are all unitary morphisms.

More interesting examples of markings are considered in Section [14]. \qedsymbol
3 Adjunctions

The inclusions in the chain (2.1) are right or left adjoints of adjunctions which we will now describe. The presence of these adjunctions turns out to be useful at various places. They will be lifted to infinity-categorical versions in Section 5.

As a convention we will denote forgetful functors by the symbol $\mathcal{F}$ with a subscript indicating which structure or property is forgotten. Most of the functors below come in two versions, one for the unmarked and one for the marked case. We will use the same notation for both.

Given a (marked) category $\mathbf{A}$ we can form the free (marked) $\ast$-category $\text{Free}_{\ast}(\mathbf{A})$ on $\mathbf{A}$. We have adjunctions

$$\text{Free}_{\ast} : \mathbf{Cat}_1 \rightleftarrows \ast \mathbf{Cat}_1 : \mathcal{F}_\ast,$$

$$\text{Free}_{\ast} : \mathbf{Cat}_1^+ \rightleftarrows \ast \mathbf{Cat}_1^+ : \mathcal{F}_\ast$$

where $\mathcal{F}_\ast$ denotes the functor which forgets the $\ast$-operation.

**Remark 3.1.** If $\mathbf{A}$ is a category, then $\text{Free}_{\ast}(\mathbf{A})$ is obtained from $\mathbf{A}$ by adding a morphism $f^* : a' \to a$ for every morphism $f : a \to a'$ in $\mathbf{A}$ with the only relation that $(f \circ g)^* = g^* \circ f^*$.

A marked category (i.e., an object of $\mathbf{Cat}_1^+$) is a category with a distinguished set of isomorphisms. For a marked category $\mathbf{A}$, in the definition of $\text{Free}_{\ast}(\mathbf{A})$, we adopt the additional relation $f^* = f^{-1}$ for all marked marked morphisms $f$ of $\mathbf{A}$ (which are isomorphisms).

We furthermore have adjunctions

$$\text{Lin}_\mathbb{C} : \ast \mathbf{Cat}_1 \rightleftarrows \ast \mathbb{C}\mathbf{Cat}_1 : \mathcal{F}_\mathbb{C}, \quad \text{Lin}_\mathbb{C} : \ast \mathbf{Cat}_1^+ \rightleftarrows \ast \mathbb{C}\mathbf{Cat}_1^+ : \mathcal{F}_\mathbb{C}$$

where $\text{Lin}_\mathbb{C}$ is the linearization functor and $\mathcal{F}_\mathbb{C}$ denotes the functor which forgets the $\mathbb{C}$-linear structure.

**Remark 3.2.** Here is the explicit description of $\text{Lin}_\mathbb{C}$. If $\mathbf{A}$ is a $\ast$-category, then $\text{Lin}_\mathbb{C}(\mathbf{A})$ has the same objects as $\mathbf{A}$, but its $\mathbb{C}$-vector space of morphisms is given by

$$\text{Hom}_{\text{Lin}_{\mathbb{C}}(\mathbf{A})}(a, a') := \mathbb{C}[\text{Hom}_{\mathbf{A}}(a, a')]$$

and the composition is defined in the canonical way.

The functor $\ast : \text{Lin}_\mathbb{C}(\mathbf{A}) \to \text{Lin}_\mathbb{C}(\mathbf{A})^{op}$ is defined as the anti-linear extension of $\ast$ on $\mathbf{A}$.

For a set $X$ and an element $x$ of $X$ we consider $x$ as an element of the complex vector space $\mathbb{C}[X]$ generated by $X$ in the canonical way. This gives a canonical map of sets $X \to \mathbb{C}[X]$.

In the marked case the set of marked morphisms in $\text{Hom}_{\text{Lin}_\mathbb{C}(\mathbf{A})}(a, a')$ is defined to be the image of the set of marked morphisms in $\mathbf{A}$ under the canonical map

$$\text{Hom}_{\mathbf{A}}(a, a') \to \mathbb{C}[\text{Hom}_{\mathbf{A}}(a, a')] = \text{Hom}_{\text{Lin}_\mathbb{C}(\mathbf{A})}(a, a').$$
For a $\mathbb{C}$-linear $\ast$-category $B$ we check the natural bijection
\[
\text{Hom}_{\ast\text{-Cat}_{1}}(\operatorname{Lin}_{\mathbb{C}}(A), B) \cong \text{Hom}_{\ast\text{-Cat}_{1}}(A, \mathcal{F}_{\mathbb{C}}(B))
\] (3.3)
It identifies a morphism $\Phi : A \to \mathcal{F}_{\mathbb{C}}(B)$ with a morphism $\Psi : \operatorname{Lin}_{\mathbb{C}}(A) \to B$. The functors coincide on objects. Given $\Phi$ and a morphism $f$ in $\text{Hom}_{\text{Lin}_{\mathbb{C}}(A)}(a, a')$ we define
\[
\Psi(f) := \sum_{\phi \in \text{Hom}_{A}(a, a')} \lambda_{\phi} \Phi(\phi)
\]
in $\text{Hom}_{B}(\Phi(a), \Phi(a'))$, where the equality $f = \sum_{\phi \in \text{Hom}_{A}(a, a')} \lambda_{\phi} \phi$ uniquely determines the collection of complex numbers $(\lambda_{\phi})_{\phi \in \text{Hom}_{A}(a, a')}$. Vice versa, if $\Psi$ is given, then for $f$ in $\text{Hom}_{A}(a, a')$ we define $\Phi(f) := \Psi(f)$ in $\text{Hom}_{B}(\Psi(a), \Psi(a'))$.

In the marked case, by an inspection of these explicit formulas, one checks that the bijection (3.3) restricts to a bijection between the sets of morphisms between marked objects.

**Remark 3.3.** If $B$ contains zero objects, then $\text{Hom}_{\ast\text{-Cat}_{1}}(B, \operatorname{Lin}_{\mathbb{C}}(A)) = \emptyset$ for every $\ast$-category $A$. □

We have adjunctions
\[
\text{Compl} : C_{\text{pre}}^{\ast\text{-Cat}_{1}} \rightleftharpoons C^{\ast\text{-Cat}_{1}} : \mathcal{F}_{\ast}, \quad \text{Compl} : C_{\text{pre}}^{\ast\text{-Cat}_{1}^+} \rightleftharpoons C^{\ast\text{-Cat}_{1}^+} : \mathcal{F}_{\ast}
\] (3.4)
where $\mathcal{F}_{\ast}$ forgets the completeness condition and Compl is the completion functor.

**Remark 3.4.** In the following we give an explicit description of the completion functor. Let $A$ be a pre-$\mathcal{C}^{\ast}$-category. The completion functor is the identity on objects. Furthermore, it completes the morphism spaces in the norm $\| - \|_{\max}$. Note that this completion involves factoring out the subspace of elements of zero norm. In this completion process the objects $a$ of $A$ with $\| \text{id}_{a} \| = 0$ become zero objects.

In the marked case the set of marked morphisms in $\text{Hom}_{\text{Compl}(A)}(a, a')$ is defined to be the image of the set of marked morphisms in $\text{Hom}_{A}(a, a')$ under the natural map $\text{Hom}_{A}(a, a') \to \text{Hom}_{\text{Compl}(A)}(a, a')$. This is well-defined since this map preserves unitaries.

Let us check the bijection
\[
\text{Hom}_{C^{\ast}\text{-Cat}_{1}}(\text{Compl}(A), B) \cong \text{Hom}_{C^{\ast}_{\text{pre}}\text{-Cat}_{1}}(A, \mathcal{F}_{\ast}(B))
\] (3.5)
for a $\mathcal{C}^{\ast}$-category $B$. This bijection sends a morphism $\Phi : A \to \mathcal{F}_{\ast}(B)$ to a morphism $\Psi : \text{Compl}(A) \to B$ and vice versa. These functors coincide on objects. Given $\Phi$ we can define $\Psi$ by extension by continuity (using that the morphism spaces in $B$ are complete). Note that $\Phi$ necessarily annihilates all morphisms of zero norm and therefore factorizes over the quotients taken in the process of completion.

Vice versa, given $\Psi$ we define $\Phi$ by restriction along the natural maps
\[
\text{Hom}_{A}(a, a') \to \text{Hom}_{\text{Compl}(A)}(a, a')
\]
for all pairs of objects \( a, a' \) of \( A \).

One easily checks that these processes are inverse to each other.

In the marked case we observe by an inspection that the bijection \( (3.5) \) identifies morphisms between marked objects.

**Example 3.5.** We continue with Example 2.2. The linearization

\[
\text{Lin}_\mathbb{C}(BG) \cong \mathbb{C}[G]
\]

of \( G \) with its usual involution is a \( \mathbb{C} \)-linear \(*\)-category. It is actually a pre-\( C^* \)-category. In order to see this note that the elements of the group go to partial isometries in every representation. Furthermore,

\[
\text{End}_{\text{Compl}(\text{Lin}_\mathbb{C}(BG))}(pt) =: C^*_{\text{max}}(G)
\]

is the maximal group-\( C^* \)-algebra.

**Example 3.6.** We consider the \( \mathbb{C} \)-linear \(*\)-category \( A \) from Example 2.8. We get \( \text{Compl}(A) \cong 0 \).

The relation between \( \mathbb{C} \)-linear \(*\)-categories and pre-\( C^* \)-categories is more complicated. Let \( A \) be a \( \mathbb{C} \)-linear \(*\)-category. Then we can define a subcategory \( \text{Bd}(A) \) of \( A \) which has the same objects as \( A \), and whose morphisms are those morphisms of \( A \) with finite maximal norm. Note that \( \text{Bd}(A) \) is closed under composition and contains the identities of the objects since they are sent to selfadjoint projections in any representation of \( A \) in a \( C^* \)-algebra and therefore have maximal norm bounded above by 1. Hence \( \text{Bd}(A) \) is indeed a category. It is furthermore clear that \( \text{Bd}(A) \) is a \( \mathbb{C} \)-linear \(*\)-category with enrichment and \(*\)-operation induced from \( A \).

Since \( \text{Bd}(A) \) may have representations to \( C^* \)-algebras which do not extend to \( A \) we can not expect that \( \text{Bd}(A) \) is a pre-\( C^* \)-category. But we can iterate the construction and consider

\[
\text{Bd}^\infty(A) := \bigcap_{n \in \mathbb{N}} \text{Bd}^n(A).
\]

This is a \( \mathbb{C} \)-linear \(*\)-subcategory of \( A \).

Assume now that \( A \) is a marked \( \mathbb{C} \)-linear \(*\)-category. Then all marked morphisms of \( A \) also belong to \( \text{Bd}(A) \) since unitary morphisms in \( A \) have norm bounded by one. So \( \text{Bd}(A) \) and hence \( \text{Bd}^\infty(A) \) has a canonical marking consisting of all marked morphisms in \( A \).

**Example 3.7.** We continue with Example 2.12. The bounded elements in \( \mathbb{C}[x] \) are the constant polynomials. Hence \( \text{Bd}(\mathbb{C}[x]) \cong \Delta^0_{\text{Cat}_1} \).

Let \( A \) be a (marked) \( \mathbb{C} \)-linear \(*\)-category.

**Lemma 3.8.**
1. $\text{Bd}^\infty(\mathbf{A})$ is a (marked) pre-$C^*$-category.

2. Any functor $\mathbf{C} \to \mathbf{A}$ of (marked) $\mathbf{C}$-linear $\ast$-categories where $\mathbf{C}$ is a (marked) pre-$C^*$-category factorizes uniquely over $\text{Bd}^\infty(\mathbf{A})$.

3. There are adjunctions

$$F_{\text{pre}} : C^*_\text{pre}\text{Cat}_1 \rightleftarrows \ast\text{Cat}_1 : \text{Bd}^\infty \ , \ F_{\text{pre}}^+ : C^*_\text{pre}\text{Cat}_1^+ \rightleftarrows \ast\text{Cat}_1^+ : \text{Bd}^\infty$$

where $F_{\text{pre}}$ denotes the inclusion.

Proof. We can identify $\text{Bd}^\infty(\mathbf{A}) \cong \text{Bd}(\text{Bd}^\infty(\mathbf{A}))$. Let $f$ be a morphism in $\text{Bd}^\infty(\mathbf{A})$. Then we can consider $f$ as a morphism in $\text{Bd}(\text{Bd}^\infty(\mathbf{A}))$ which implies that $f$ has a finite maximal norm. This proves 1.

Let $\phi : \mathbf{C} \to \mathbf{A}$ be a morphism of $\mathbf{C}$-linear $\ast$-categories where $\mathbf{C}$ is a pre-$C^*$-category. We show 2 by contradiction. Assume that there exists a natural number $n$ such that $\phi(\mathbf{C}) \subseteq \text{Bd}^n(\mathbf{A})$, but $\phi(\mathbf{C}) \not\subseteq \text{Bd}^{n+1}(\mathbf{A})$. Then there exists a morphism $f$ in $\mathbf{C}$ and a family of representations $(\rho_k)_{k \in \mathbb{N}}$ of $\text{Bd}^n(\mathbf{A})$ in a family of $C^*$-algebras $(B_k)_{k \in \mathbb{N}}$ such that $\|\rho_k(\phi(f))\|_{B_k} \geq k$ for every natural number $k$. Since the composition $\rho_k \circ \phi$ is a representation of $\mathbf{C}$ we see that $k \leq \|f\|_{\text{max}}$ for all every natural number $k$. This contradicts the assumption that $\mathbf{C}$ is a pre-$C^*$-category.

In the marked case we observe that $\phi$ sends marked morphisms in $\mathbf{C}$ to $\text{Bd}^\infty(\mathbf{A})$ since marked morphisms are unitary and $\phi$ preserves unitaries.

The Assertion 3 now follows from Assertion 2.

Let $\mathcal{C}$ be a member of the list

$$\{\text{Cat}_1, \ast\text{Cat}_1, \ast\text{Cat}_1, C^*_\text{pre}\text{Cat}_1, C^*\text{Cat}_1\}$$

and $\mathcal{C}^+$ denote the corresponding marked version. We have a canonical functor $\mathcal{F}_+ : \mathcal{C}^+ \to \mathcal{C}$ which forgets the marking. This functor fits into adjunctions

$$\text{mi} : \mathcal{C} \rightleftarrows \mathcal{C}^+ : \mathcal{F}_+ \ , \ \mathcal{F}_+ : \mathcal{C}^+ \rightleftarrows \mathcal{C} : \text{ma}$$

The left-adjoint $\text{mi}$ of $\mathcal{F}_+$ marks the identities, and the right-adjoint $\text{ma}$ marks all unitaries (or invertibles in the case of $\text{Cat}_1$, respectively).
4 Classifier categories

In this section we discuss the representability of the functors which take the sets objects, (bounded) morphisms, unitary morphisms (or marked morphisms) of a (marked) $*$-category in the respective cases. The role of this section is an illustration. We use the opportunity to explain the categorical meaning of the examples which will be used later.

Let $\mathcal{C}$ be in the list

$$\{ \text{Cat}_1, \text{*Cat}_1, \text{cCat}_1, \text{C}_{pr}^* \text{Cat}_1, \text{C}^* \text{Cat}_1, \text{Cat}_1^+, \text{*Cat}_1^+, \text{cCat}_1^+, \text{C}_{pr}^* \text{Cat}_1^+, \text{C}^* \text{Cat}_1^+ \} .$$

**Lemma 4.1.** The functor $\mathcal{C} \to \text{Set}$ which sends a category in $\mathcal{C}$ to its set of objects is representable.

**Definition 4.2.** The object $\Delta^0_{\mathcal{C}}$ which represents this functor will be called the object classifier.

**Proof.** This is a case-by-case discussion. In $\text{Cat}_1$ we can set

$$\Delta^0_{\text{Cat}_1} := pt ,$$

the category with one object $pt$ and one morphism $\text{id}_{pt}$. Then in view of the adjunction (3.1) we have

$$\Delta^0_{\text{Cat}_1} \cong \text{Free}_*(\Delta^0_{\text{Cat}_1}) .$$

Its underlying category is again $\Delta^0_{\text{Cat}_1}$.

In view of the adjunction (3.2) we have

$$\Delta^0_{\text{cCat}_1} \cong \text{Lin}_C(\Delta^0_{\text{Cat}_1}) .$$

This is the $C$-linear $*$-category associated to the $C^*$-algebra $C$ and hence is a $C^*$-category. We conclude that

$$\Delta^0_{\text{C}^* \text{Cat}_1} \cong \Delta^0_{\text{C}_{pr}^* \text{Cat}_1} \cong \Delta^0_{\text{cCat}_1}$$

(as $C$-linear $*$-categories). For $\mathcal{C}$ in the list

$$\{ \text{Cat}_1, \text{*Cat}_1, \text{cCat}_1, \text{C}_{pr}^* \text{Cat}_1, \text{C}^* \text{Cat}_1 \}$$

the marked version of the object classifier is characterized by

$$\Delta^0_{\mathcal{C}^+} \cong \text{mi}(\Delta^0_{\mathcal{C}}) ,$$

see (3.7) for notation. $\square$

Usually we will omit the subscript $\mathcal{C}$ when the context is clear and just write $\Delta^0$ for the object classifier. A similar conventions applies to the other classifier objects below.
Lemma 4.3. For $C$ in $\{\text{Cat}_1, \ast\text{Cat}_1, \ast\ast\text{Cat}_1, \text{Cat}_1^{+}, \ast\text{Cat}_1^{+}, \ast\ast\text{Cat}_1^{+}\}$ the functor $C \to \text{Set}$ which sends a category in $C$ to its set of morphisms is representable.

For $C$ in $\{C^*\text{-preCat}_1, C^*\text{Cat}_1, C^*\text{preCat}_1^{+}, C^*\text{Cat}_1^{+}\}$ this functor is not representable.

Definition 4.4. The object $\Delta^1_C$ which represents this functor will be called the morphism classifier.

Proof. This is again a case-by-case discussion. The morphism classifiers have two objects 0 and 1 corresponding to the source and target of the morphism.

In $\text{Cat}_1$ we let $\Delta^1_{\text{Cat}_1}$ be the category with one non-trivial morphism $a : 0 \to 1$. Then in view of the adjunction (3.1) we have

$$\Delta^1_{\text{Cat}_1} \cong \text{Free}_s(\Delta^1_{\text{Cat}_1}).$$

For example, a morphism $0 \to 1$ in this category is a word $aa^*aa^*\ldots a^*a$. In view of the adjunction (3.2) we have

$$\Delta^1_{\text{Cat}_1} \cong \text{Lin}_C(\Delta^1_{\text{Cat}_1}).$$

In the marked cases, for $C$ in the list $\{\text{Cat}_1, \ast\text{Cat}_1, \ast\ast\text{Cat}_1\}$, the morphism classifiers are characterized by

$$\Delta^1_{\ast\text{Cat}_1} \cong \text{mi}_C(\Delta^1_C).$$

We now come to the non-existence assertion. Assume that the pre-$C^*$-category $C$ represents the morphism-set functor in $C^*\text{-preCat}_1$. Let $a : 0 \to 1$ be the universal morphism. As in any non-trivial pre-$C^*$-category there exists morphisms of arbitrary large maximal norm (just scale) we have $\|a\|_{\text{max}} = \infty$ contradicting the assumption that $C$ is a pre-$C^*$-category. The same reasoning applies to $C^*\text{Cat}_1$ and the marked versions.

The following replaces the morphisms classifier in the $C^*$-category cases. Let $C$ be a member of the list $\{C^*\text{Cat}_1, C^*\text{Cat}_1^{+}\}$. The following result is [Del10, Ex. 3.8]

Lemma 4.5. The functor $C \to \text{Set}$ which sends a category in $C$ to its set of morphisms with maximal norm bounded by 1 is representable.

Definition 4.6. The object $\Delta^1_{C,\text{bd}}$ which represents this functor will be called the bounded morphism classifier.

Proof. In order to construct the bounded morphism classifier for $C^*\text{Cat}_1$ we start with the $C$-linear $*$-category

$$\Delta^1_{C^*\text{Cat}_1} \cong \text{Lin}_C(\text{Free}_s(\Delta^1_{\text{Cat}_1})).$$

The universal morphism $a$ in $\Delta^1_{\ast\text{Cat}_1}$ can be considered as a morphism of $\Delta^1_{\ast\text{Cat}_1}$ in the natural way. We add formal inverses of $\lambda \text{id}_0 - a^*a$ in $\text{End}_{\Delta^1_{\ast\text{Cat}_1}}(0)$ and $\lambda \text{id}_1 - aa^*$ in $\text{End}_{\Delta^1_{\ast\text{Cat}_1}}(1)$ for all $\lambda$ in $C$ with $|\lambda| > 1$ and obtain a new $C$-linear $*$-category $\Delta^1_{C^*\text{Cat}_1}$.
Spectral theory implies that \( \|a\|_{\text{max}} = \|a^*\|_{\text{max}} \leq 1 \). Hence \( \Delta_{C^*\text{Cat}_1}^1 \) is a pre-\( C^* \)-category. One easily checks that
\[
\Delta_{C^*\text{Cat}_1}^{1,bd} := \text{Compl}(\Delta_{C^*\text{Cat}_1}^1)
\]
have the required universal properties. In the marked case we have
\[
\Delta_{C^*\text{Cat}_1}^{1,bd} \cong \text{mi}(\Delta_{C^*\text{Cat}_1}^{1,bd})
\]
\[\square\]

**Remark 4.7.** We do not know whether \( C^*_{\text{pre Cat}_1}(+) \) has a bounded morphism classifier or an appropriate replacement. This is the reason that we can not show that the model category structure on \( C^*_{\text{pre Cat}_1}(+) \) is cofibrantly generated. \[\square\]

We now discuss unitaries.

**Remark 4.8.** If \( u \) is a unitary morphism in a \( \mathbb{C} \)-linear \( * \)-category, then any representation sends \( u \) to a partial isometry. Hence \( \|u\|_{\text{max}} \leq 1 \). But it may happen that \( \|u\| = 0 \). This is e.g. the case if \( u \) is the identity of the unique object of the pre-\( C^* \)-category considered in Example 2.8.

For a \( * \)-category \( A \) the counit \( A \to \text{Lin}_\mathbb{C}(A) \) preserves unitaries. Similarly, for a pre-\( C^* \)-category \( A \) the natural morphism \( A \to \text{Compl}(A) \) preserves unitaries.

For a \( \mathbb{C} \)-linear \( * \)-category \( B \) the counit \( \text{Bd}^\infty(B) \to B \) is bijective on unitaries. \[\square\]

Let \( C \) be in the list
\[
\{ *\text{Cat}_1, *_{\mathbb{C}}\text{Cat}_1, C^*_{\text{pre Cat}_1}, C^*\text{Cat}_1, *\text{Cat}_1^+, *_{\mathbb{C}}\text{Cat}_1^+, C^*_{\text{pre Cat}_1}^+, C^*\text{Cat}_1^+ \}
\]

**Lemma 4.9.** The functor \( C \to \text{Set} \) which sends a category in \( C \) to its set of unitary morphisms is representable.

**Definition 4.10.** The object \( 1_C \) which represents this functor will be called the unitary morphism classifier.

**Proof.** We perform a case-by-case discussion. In \( *\text{Cat}_1 \) we define \( 1_{\text{Cat}_1} \) to be the category with objects 0 and 1 and non-trivial morphisms \( u : 0 \to 1 \) and \( u^* = u^{-1} : 1 \to 0 \). In view of the adjunction (3.2) we have
\[
1_{*\text{Cat}_1} \cong \text{Lin}_\mathbb{C}(1_{*\text{Cat}_1})
\]
Since the generator \( u \) is sent to a unitary in any representation it is clear that \( 1_{*\text{Cat}_1} \) is a pre-\( C^* \)-category. Since \( \|u\|_{\text{max}} = 1 \) it is actually a \( C^* \)-category.

Hence we have isomorphisms
\[
1_{C^*\text{pre Cat}_1} \cong 1_{*\text{Cat}_1} \cong 1_{C^*\text{Cat}_1}
\]
(as \( \mathbb{C} \)-linear \( * \)-categories). In the marked cases, for \( C \) in the list \( \{ *\text{Cat}_1, *_{\mathbb{C}}\text{Cat}_1, C^*_{\text{pre Cat}_1}, C^*\text{Cat}_1 \} \) we have \( 1_C^+ \cong \text{mi}_C(1_C) \), i.e., the universal unitary in \( 1_C^+ \) is not marked. \[\square\]
Let $\mathcal{C}$ be a member of the list
\[ \{ \ast \text{Cat}_1, \ast \text{pre Cat}_1, \ast \text{Cat}_1, \text{Cat}_1 \} \]

**Lemma 4.11.** The functor $\mathcal{C}^+ \to \text{Set}$ which sends a category in $\mathcal{C}^+$ to its set of marked morphisms is representable.

**Definition 4.12.** The object $1^+_{\mathcal{C}}$ which represents this functor will be called the marked morphism classifier.

**Proof.** We have $1^+_{\mathcal{C}} \cong \text{ma}(1_{\mathcal{C}})$, i.e., the universal unitary is now marked. $\square$

We now consider just categories.

**Lemma 4.13.** The functor which sends a category to its set of invertible morphisms is representable.

**Definition 4.14.** We call a category $\mathbb{I}$ which represents this functor the classifier of invertible morphisms.

**Proof.** The groupoid $\mathbb{I}$ of the shape
\[
\begin{array}{c}
0 \\
\downarrow \\
1
\end{array}
\]
has the desired properties. The morphism $0 \to 1$ is the universal invertible morphism. $\square$

**Remark 4.15.** The groupoid $\mathbb{I}$ is also the morphism classifier in $\text{Grpd}_1$. $\square$

## 5 Unitary equivalences and $\infty$-categories of $\ast$-categories

In this section we introduce the $\infty$-categories of $\ast$-categories, $\mathbb{C}$-linear $\ast$-categories, pre-$\ast$-categories, $\ast$-categories and their marked versions by inverting unitary (or marked, respectively) equivalences.

Let $\mathcal{C}$ belong to the list
\[ \{ \ast \text{Cat}_1, \ast \text{pre Cat}_1, \ast \text{Cat}_1, \ast \text{pre Cat}_1, \ast \text{Cat}_1 \} \].

Furthermore, let $f, g : A \to B$ be a parallel pair of morphisms in $\mathcal{C}$.

**Definition 5.1.** We say that $f$ and $g$ are (markedly) unitarily equivalent, if there exists a natural isomorphism of functors $u : f \to g$ such that $u(a)$ is a (marked) unitary morphism in $\text{Hom}_B(f(a), g(a))$ for every object $a$ of $A$.

Here the word markedly or marked applies in the marked cases. In these cases the word unitary can be omitted since marked morphisms are unitary by definition.

Let $f : A \to B$ be a morphism in $\mathcal{C}$. 

Definition 5.2. The morphism \( f \) is a (marked) unitary equivalence if there exists a morphism \( g \colon B \to A \) in \( C \) such that \( f \circ g \) is unitarily (markedly) isomorphic to \( \text{id}_B \) and \( g \circ f \) is (markedly) unitarily isomorphic to \( \text{id}_A \).

The following characterization of unitary or marked equivalences will be useful later. We let

\[
\mathcal{F}_{\text{all}} : C \to \text{Cat} \quad (5.1)
\]

be the functor which takes the underlying category (i.e., forgets all additional structures and properties). Furthermore, in the marked cases, we consider the functor

\[
(-)^+ : C \to \text{Cat}
\]

which takes the subcategory of marked morphisms, see Remark 2.20. Finally recall the functor \( \text{ma} \) from the unmarked to the marked versions which marks all unitaries, see (3.7).

Let \( f : A \to B \) be a morphism in \( C \).

Lemma 5.3.

1. in the marked cases: The morphism \( f \) is a marked equivalence if and only if \( \mathcal{F}_{\text{all}}(f) \) and \( f^+ \) are equivalences of categories.

2. in the unmarked cases: The morphism \( f \) is a unitary equivalence if and only if \( \mathcal{F}_{\text{all}}(f) \) and \( \text{ma}(f)^+ \) are equivalences of categories.

Proof. We start with 1. If \( f \) is a marked equivalence, then by Definition 5.2 there is an inverse morphism \( g : B \to A \) up to marked isomorphism. Then \( \mathcal{F}_{\text{all}}(g) \) and \( g^+ \) are inverse equivalences of \( \mathcal{F}_{\text{all}}(f) \) and \( f^+ \), respectively.

We now assume that \( \mathcal{F}_{\text{all}}(f) \) and \( f^+ \) are equivalences of categories. Then there exists a functor \( g^+ : B^+ \to A^+ \) and isomorphisms of functors

\[
u : \text{id}_{B^+} \to f^+ \circ g^+ \quad \text{and} \quad v : \text{id}_{A^+} \to g^+ \circ f^+.
\]

We define a morphism \( g : B \to A \) in \( C \) as follows:

1. on objects: For an object \( b \) of \( B \) we define \( g(b) := g^+(b) \).

2. on morphisms: For objects \( b, b' \) of \( B \) we define \( g : \text{Hom}_B(b, b') \to \text{Hom}_A(g(b), g(b')) \) as the composition

\[
\text{Hom}_B(b, b') \xrightarrow{\cong} \text{Hom}_B(f(g(b)), f(g(b'))) \xrightarrow{\mathcal{F}_{\text{all}}(f)} \text{Hom}_A(g(b), g(b')) ,
\]

where the isomorphism marked by ! is given by

\[
\phi \mapsto u_{b'} \circ \phi \circ u_b^{-1}
\]

and we use that \( \mathcal{F}_{\text{all}}(f) \) is an equivalence of categories for the second isomorphism.
Note that $g$ preserves marked morphisms since $u_b$ and $u_{b'}$ are marked and $\mathcal{F}_{all}(f)$ induces a bijection between the subsets of marked morphisms (since $f^+$ is assumed to be an equivalence). Furthermore, since $u_b$ and $u_{b'}$ are unitary (since marked morphisms must be unitary), $g$ is a morphism of $\ast$-categories. Finally, in the $\mathbb{C}$-enriched cases, $g$ is compatible with the enrichments.

The morphism $g$ is the required inverse to $f$ up to marked isomorphism. The transformations $u$ and $v$ can be interpreted as marked isomorphisms

$$u : \text{id}_B \to f \circ g, \quad v : \text{id}_A \to g \circ f.$$ 

We now show 2. If $f$ is a unitary equivalence, then there is an inverse morphism $g : B \to A$ up to unitary isomorphism. Then $\mathcal{F}_{all}(g)$ and $\text{ma}(g)^+$ are inverse equivalences of $\mathcal{F}_{all}(f)$ and $\text{ma}(f)^+$, respectively.

We now assume that $\mathcal{F}_{all}(f)$ and $\text{ma}(f)^+$ are equivalences of categories. Then by the first case 1 we know that $\text{ma}(f) : \text{ma}(A) \to \text{ma}(B)$ is a marked equivalence. Let $g : \text{ma}(B) \to \text{ma}(A)$ be an inverse of $\text{ma}(f)$ up to marked isomorphism. Then $\mathcal{F}_+(g) : B \to A$ ($\mathcal{F}_+$ forgets the marking, see (5.7)) is an inverse of $f$ up to unitary isomorphism.

**Remark 5.4.** In the case $\mathcal{C} = \mathbb{C}^\ast\text{Cat}_1$ it was shown in [Del10, Lemma 4.6] that a morphism $f : A \to B$ is a unitary equivalence if and only if $\mathcal{F}_{all}(f)$ is an equivalence of categories, i.e., that the second condition in Lemma 5.3.2 involving $\text{ma}(f)^+$ is redundant. The argument uses a special property of $\mathbb{C}^\ast$-categories, namely the existence of polar decompositions of morphisms [Del10, Prop. 2.6].

The following lemma about maximal norms morally belongs to Section 2 but can only be stated at this place since it involves the notion of unitary equivalences.

**Lemma 5.5.** If $\Phi : A \to B$ is a unitary equivalence between $\mathbb{C}$-linear $\ast$-categories, then for every morphism $f$ in $A$ we have $\|\Phi(f)\|_{\text{max}} = \|f\|_{\text{max}}$.

**Proof.** By precomposition with $\Phi$ every representation of $B$ in a $\mathbb{C}^\ast$-algebra yields a representation of $A$ in the same $\mathbb{C}^\ast$-algebra. This immediately implies the inequality

$$\|\Phi(f)\|_{\text{max}} \leq \|f\|.$$ 

Let now $\Psi : B \to A$ be an inverse equivalence. Then there exists a unitary morphism $u$ in $A$ such that $u \circ \Psi(\Phi(f)) \circ u^* = f$. This gives (using $\|u\|_{\text{max}} \leq 1$, see Remark 4.8)

$$\|f\|_{\text{max}} = \|u \circ \Psi(\Phi(f)) \circ u^*\|_{\text{max}} \leq \|\Psi(\Phi(f))\|_{\text{max}} \leq \|\Phi(f)\|_{\text{max}}.$$ 

**Remark 5.6.** We will use the following fact about adjunctions. We consider two relative categories $(\mathcal{C}, W_{\mathcal{C}})$ and $(\mathcal{D}, W_{\mathcal{D}})$ and a pair of adjoint functors

$$L : \mathcal{C} \rightleftharpoons \mathcal{D} : R.$$ 

(5.2)
We now assume that $L$ and $R$ are compatible with the sets $W_C$ and $W_D$ in the sense that $\ell_D \circ L$ sends the morphisms in $W_C$ to equivalences in $D[W_D^{-1}]$, and that $\ell_C \circ R$ sends the morphisms in $W_D$ to equivalences in $C[W_C^{-1}]$. Then the functors $L$ and $R$ descend essentially uniquely to functors

$$\bar{L} : C[W_C^{-1}] \rightleftarrows D[W_D^{-1}] : \bar{R}.$$ 

In this case the adjunction $L \dashv R$ naturally induces an adjunction $\bar{L} \dashv \bar{R}$. A reference for these facts is [Cis, Prop. 7.1.14].

If $L$ comes from a left Quillen functor between combinatorial model categories, then we could also proceed as sketched in [Lur17, Rem. 1.3.4.27].

Let $C$ be in the list

$$\{ *\text{Cat}_1, *\text{Cat}_1^+; C_{\text{pre}}^\ast \text{Cat}_1, C^\ast \text{Cat}_1, *\text{Cat}_1^+; C_{\text{pre}}^\ast \text{Cat}_1^+, C^\ast \text{Cat}_1^+ \} ,$$

and let $W_C$ denote the (marked) unitary equivalences in $C$ as defined in Definition 5.2.

**Definition 5.7.** We define the $\infty$-categories

$$*\text{Cat} := *\text{Cat}_1[W^{-1}_{*\text{Cat}_1}], \quad *\text{Cat}^+ := *\text{Cat}_1^+[W^{-1}_{*\text{Cat}_1^+}],$$

$$*_{\text{c}}\text{Cat} := *_{\text{c}}\text{Cat}_1[W^{-1}_{*_{\text{c}}\text{Cat}_1}], \quad *_{\text{c}}\text{Cat}^+ := *_{\text{c}}\text{Cat}_1^+[W^{-1}_{*_{\text{c}}\text{Cat}_1^+}],$$

$$C_{\text{pre}}^\ast \text{Cat} := C_{\text{pre}}^\ast \text{Cat}_1[W^{-1}_{C_{\text{pre}}^\ast \text{Cat}_1}], \quad C_{\text{pre}}^\ast \text{Cat}^+ := C_{\text{pre}}^\ast \text{Cat}_1^+[W^{-1}_{C_{\text{pre}}^\ast \text{Cat}_1^+}],$$

$$C^\ast \text{Cat} := C^\ast \text{Cat}_1[W^{-1}_{C^\ast \text{Cat}_1}], \quad C^\ast \text{Cat}^+ := C^\ast \text{Cat}_1^+[W^{-1}_{C^\ast \text{Cat}_1^+}].$$

$\bar{u} : \text{id}_{\mathcal{C}[W_C^{-1}]} \to R \circ L$.

We must show that $\bar{u}$ is a unit transformation in the sense of [Lur09, Def. 5.2.2.7], i.e., that for any two objects $C$ in $\mathcal{C}[W_C^{-1}]$ and $D$ in $\mathcal{D}[W_D^{-1}]$ the induced morphism

$$\text{Map}_{\mathcal{D}[W_D^{-1}]}(C, D) \xrightarrow{R} \text{Map}_{\mathcal{C}[W_C^{-1}]}(R(L(C)), R(D))$$

is an equivalence of spaces. Using the fact that $\bar{u}$ and $\bar{v} : \bar{L} \circ \bar{R} \to \text{id}_{\mathcal{D}[W_D^{-1}]}$ induced by $v$ satisfy the triangle identities up to equivalence we see that the desired inverse equivalence is given by

$$\text{Map}_{\mathcal{D}[W_D^{-1}]}(L(C), D) \xrightarrow{\bar{v}(D)} \text{Map}_{\mathcal{C}[W_C^{-1}]}(L(C), \bar{R}(D)),$$

$$\text{Map}_{\mathcal{C}[W_C^{-1}]}(C, \bar{R}(D)) \xrightarrow{\bar{L}} \text{Map}_{\mathcal{D}[W_D^{-1}]}(\bar{L}(C), \bar{R}(D)),$$

$$\text{Map}_{\mathcal{D}[W_D^{-1}]}(L(C), D) \xrightarrow{\bar{v}(D)} \text{Map}_{\mathcal{C}[W_C^{-1}]}(L(C), \bar{R}(D)).$$
Lemma 5.8. The adjunctions (3.2) induce adjunctions

\[ \text{Lin}_C : \ast \text{Cat} \rightleftarrows \ast \text{Cat}^+ : \mathcal{F}_C, \quad \text{Lin}_C : \ast \text{Cat} : \mathcal{F}_C \]  

(5.3)

Proof. We observe that the forgetful functor \( \mathcal{F}_C \) and the linearization functor \( \text{Lin}_C \) preserve (marked) unitary equivalences. Hence they descend naturally to the \( \infty \)-categories. By Remark 5.6 we obtain an adjunction between these descended functors. □

Lemma 5.9. The adjunctions (3.4) induce adjunctions

\[ \text{Compl} : \ast \text{pre} \text{Cat} \rightleftarrows \ast \text{Cat} : \mathcal{F}_- , \quad \text{Compl} : \ast \text{pre} \text{Cat}^+ \rightleftarrows \ast \text{Cat}^+ : \mathcal{F}_- \]  

(5.4)

Proof. We first observe that the forgetful functor \( \mathcal{F}_- \) and the completion functor \( \text{Compl} \) preserve (marked) unitary equivalences. Hence they descend naturally to the \( \infty \)-categories. By Remark 5.6 we obtain an adjunction between these descended functors. □

Lemma 5.10. The adjunctions (3.6) induce adjunctions

\[ \mathcal{F}_\text{pre} : \ast \text{pre} \text{Cat} \rightleftarrows \ast \text{pre} \text{Cat} : \text{Bd}^\infty , \quad \mathcal{F}_\text{pre} : \ast \text{pre} \text{Cat}^+ \rightleftarrows \ast \text{pre} \text{Cat}^+ : \text{Bd}^\infty . \]  

(5.5)

Proof. The forgetful functor \( \mathcal{F}_\text{pre} \) preserves (marked) unitary equivalences. The operation \( \text{Bd}^\infty \) also preserves (marked) unitary equivalences since \( \text{Bd}^\infty (\mathcal{A}) \) contains all unitary (marked, resp.) morphisms of \( \mathcal{A} \). Hence both functors descend naturally to the \( \infty \)-categories. By Remark 5.6 we obtain an adjunction between these descended functors. □

Convention 5.11. We use the same notation \( \ell \) for all the localization functors: For \( C \) in the list

\[ \{ \ast \text{Cat}_1, \ast \text{pre} \text{Cat}_1, \ast \text{Cat}^+_1, \ast \text{pre} \text{Cat}^+_1, \ast \text{Cat}^+_1, \ast \text{pre} \text{Cat}^+_1, \ast \text{Cat}^+_1 \} \]

we write

\[ \ell : C \rightarrow C_\infty \]  

(5.6)

for the corresponding localization. □

6 The tensor and power structure over groupoids

In this section we let \( \mathcal{G} \) be a category. Later we will assume that it is a groupoid.

For a category \( \mathcal{A} \) we consider the functor category \( \mathcal{F}un(\mathcal{G}, \mathcal{A}) \) whose objects are functors from \( \mathcal{G} \) to \( \mathcal{A} \), and whose morphisms are natural transformations between functors. If \( \mathcal{A} \) is a \( \ast \)-category, then we define an involution

\[ \ast : \mathcal{F}un(\mathcal{G}, \mathcal{A}) \rightarrow \mathcal{F}un(\mathcal{G}, \mathcal{A}) \]

such that it sends a morphism \( f = (f_g)_{g \in \mathcal{G}} : a \rightarrow a' \) in \( \mathcal{F}un(\mathcal{G}, \mathcal{A}) \) with \( f_g : a(g) \rightarrow a'(g) \) to the morphism \( f^* := (f^*_g)_{g \in \mathcal{G}} : a' \rightarrow a \).
Assume furthermore that $A$ is a $\mathbb{C}$-linear $\ast$-category. Then the enrichment of $A$ over complex vector spaces naturally induces an enrichment of $\mathcal{F}un(G, A)$. In this case $\mathcal{F}un(G, A)$ has the structure of a $\mathbb{C}$-linear $\ast$-category. If $A$ is marked, then $\mathcal{F}un(G, A)$ is a marked $\ast$-category or marked $\mathbb{C}$-linear $\ast$-category whose marked morphisms are those transformations $(f_g)_{g \in G}$ where $f_g$ is marked for all $g$ in $G$.

For $C$ in the list

$$\{^\ast\text{Cat}_1, ^\ast\text{Cat}_1^+, ^\ast_c \text{Cat}_1, ^\ast_c \text{Cat}_1^+\}$$

we therefore get a functor

$$\mathcal{F}un(-, -) : \text{Cat}_1^{op} \times C \to C.$$ 

Let $A$ be a (marked) $\ast$-category.

**Definition 6.1.** We call a functor $a$ in $\mathcal{F}un(G, A)$ (marked) unitary if $a(\phi)$ is unitary (marked) for all morphisms $\phi$ in $\text{Hom}_G(g, h)$.

We let $\mathcal{F}un^u(G, A)$ denote the full subcategory of $\mathcal{F}un(G, A)$ of unitary functors. It is a $\ast$-category by Remark 2.16. Similarly, if $A$ is a $\mathbb{C}$-linear $\ast$-category, then so is $\mathcal{F}un^u(G, A)$.

If $A$ is marked, then we let $\mathcal{F}un^u(G, A)$ denote the full subcategory of $\mathcal{F}un(G, A)$ of marked functors. It is again a marked $\ast$-category. If $A$ is a marked $\mathbb{C}$-linear $\ast$-category, then so is $\mathcal{F}un^u(G, A)$.

For $C$ in the list

$$\{^\ast\text{Cat}_1, ^\ast_c \text{Cat}_1, ^\ast\text{Cat}_1^+, ^\ast_c \text{Cat}_1^+\}$$

we have a functor

$$\mathcal{F}un^u(-, -) : \text{Cat}_1^{op} \times C \to C.$$ 

**Remark 6.2.** In the marked case the notation $\mathcal{F}un^u(G, A)$ is actually an abuse of notation since this could also be interpreted as the category of unitary functors between $G$ and $A$ after forgetting the marking. But we prefer to use this notation with the interpretation as above in order to state formulas below in a form which applies to the unmarked as well as to the marked cases.

If $A$ is a (marked) pre-$C^\ast$-category or a (marked) $C^\ast$-category, then as a convention, in order to form the (marked) $\mathbb{C}$-linear $\ast$-category $\mathcal{F}un^u(G, A)$ we will consider $A$ as a (marked) $\mathbb{C}$-linear category and interpret $\mathcal{F}un^u(G, A)$ as a (marked) $\mathbb{C}$-linear $\ast$-category. $\square$

**Remark 6.3.** If $C$ is a $C^\ast$-category, then we can not expect that $\mathcal{F}un^u(G, A)$ is a $C^\ast$-category again. For the simplest counter example let $G$ be an infinite set and $A$ be the category associated to a $C^\ast$-algebra $A$. Then $\mathcal{F}un^u(G, A)$ is the $\mathbb{C}$-linear $\ast$-category with one object and with morphisms $\prod G A$. But this is not even a pre-$C^\ast$-category. In order to get a $C^\ast$-category, for the morphisms we should take the uniformly bounded sequences $\prod_{g \in G} A$. So we must define a uniformly bounded subfunctor

$$\mathcal{F}un^{bd}(G, A) \subseteq \mathcal{F}un^u(G, A).$$ 

$\square$
Definition 6.4. For a (marked) $\mathbb{C}$-linear $\ast$-category $\mathbf{A}$ we define uniformly bounded sub-functor by

$$\mathcal{F}un^{bd}(G, \mathbf{A}) := Bd^{\infty}(\mathcal{F}un^u(G, \mathbf{A})) .$$

By definition $\mathcal{F}un^{bd}(G, \mathbf{A})$ is a (marked) pre-$C^\ast$-category. In particular, for $\mathcal{C}$ in the list $\{C^\ast_{pre}\mathbf{Cat}_1, C^\ast_{pre}\mathbf{Cat}_1^\ast\}$ we have defined a functor

$$\mathcal{F}un^{bd}(-, -) : \mathbf{Cat}^{op} \times \mathcal{C} \to \mathcal{C} .$$

Example 6.5. We have $\mathcal{F}un^{bd}(\Delta^0_{\mathbf{Cat}_1}, \mathbf{A}) \cong \text{Bd}^{\infty}(\mathbf{A})$. \hfill $\square$

Example 6.6. Assume that $\mathbf{G}$ is a set and that $\mathbf{A}$ is associated to a $C^\ast$-algebra $A$. Then $\mathcal{F}un^{bd}(\mathbf{G}, \mathbf{A})$ can be identified with the category with one object and the morphisms given by the $C^\ast$-algebra $\prod_{g \in \mathbf{G}} A$. \hfill $\square$

Remark 6.7. If $\mathbf{A}$ is a $C^\ast$-category, then at the moment we do not know whether $\mathcal{F}un^{bd}(\mathbf{G}, \mathbf{A})$ is again a $C^\ast$-category, but see Corollary 6.17.

We have an obvious candidate $\mathcal{F}un^r(\mathbf{G}, \mathbf{A})$ for the functor $C^\ast$-category which is also defined as a subcategory of $\mathcal{F}un^u(\mathbf{G}, \mathbf{A})$ as follows. The objects of $\mathcal{F}un^r(\mathbf{G}, \mathbf{A})$ are the objects of $\mathcal{F}un^u(\mathbf{G}, \mathbf{A})$. Given two functors $a, a'$ in $\mathcal{F}un^u(\mathbf{G}, \mathbf{A})$ we have an inclusion

$$\text{Hom}_{\mathcal{F}un^u(\mathbf{G}, \mathbf{A})}(a, a') \subseteq \prod_{g \in \mathbf{G}} \text{Hom}_\mathbf{A}(a(g), a'(g)) ,$$

where a family $(f_g)_{g \in \mathbf{G}}$ is a transformation of functors if for every morphism $\phi$ in $\text{Hom}_{\mathbf{G}}(g, h)$

$$f_h \circ a(\phi) = a'(\phi) \circ f_g .$$ (6.1)

We now define the morphisms of $\mathcal{F}un^r(\mathbf{G}, \mathbf{A})$ by

$$\text{Hom}_{\mathcal{F}un^r(\mathbf{G}, \mathbf{A})}(a, a') := \text{Hom}_{\mathcal{F}un^u(\mathbf{G}, \mathbf{A})}(a, a') \cap \prod_{g \in \mathbf{G}} \text{Hom}_\mathbf{A}(a(g), a'(g)) .$$

Since the relations (6.1) are linear and continuous the morphism space $\text{Hom}_{\mathcal{F}un^r(\mathbf{G}, \mathbf{A})}(a, a')$ is a closed linear subspace of the Banach space $\prod_{g \in \mathbf{G}} \text{Hom}_\mathbf{A}(a(g), a'(g))$ with the norm

$$\| (f_g)_{g \in \mathbf{G}} \| := \sup_{g \in \mathbf{G}} \| f_g \|_{\text{max}} .$$

So $\text{Hom}_{\mathcal{F}un^r(\mathbf{G}, \mathbf{A})}(a, a')$ inherits a Banach space structure. Let now $f \in \text{Hom}_{\mathcal{F}un^r(\mathbf{G}, \mathbf{A})}(a, a')$. Then we have

$$\| f^* \circ f \| = \sup_{g \in \mathbf{G}} \| f^*_g \circ f_g \| = \sup_{g \in \mathbf{G}} \| f_g \| = \| f \| ,$$

i.e., the $C^\ast$-identity is satisfied. Similarly we conclude the $C^\ast$-inequality.$\square$ It follows from the universal property of $\text{Bd}^{\infty}$ that we have a morphism of $\mathbb{C}$-linear $\ast$-categories

$$\mathcal{F}un^r(\mathbf{G}, \mathbf{A}) \to \mathcal{F}un^{bd}(\mathbf{G}, \mathbf{A}) .$$

We do not know whether this is an isomorphism. \hfill $\square$
Definition 6.8. If $A$ is a (marked) $\mathbb{C}$-linear $*$-category, then we define the (marked) $\mathbb{C}^*$-category
$$\mathcal{F}un^{\mathbb{C}^*}(G, A) := \text{Compl}(\mathcal{F}un^{bd}(G, A)).$$

In particular, for $\mathcal{C}$ in the list $\{\mathbb{C}^*\text{Cat}_1, \mathbb{C}^*\text{Cat}_1^+\}$ we have defined a functor
$$\mathcal{F}un^{\mathbb{C}^*}(-, -) : \mathcal{C}^{op} \times \mathcal{C} \to \mathcal{C}.$$

Remark 6.9. Later in Corollary 6.17 we will see that the completion is not necessary if $G$ is a groupoid.

Let $G$ be a groupoid and $A$ be a $*$-category. We consider $G$ as a $*$-category in the canonical manner (see Example 2.2) and form the $*$-category $A \times G$ (the existence of the product is ensured by Theorem 8.1). Explicitly, the $*$-category $A \times G$ is the product category with the $*$-operation
$$(f, \phi)^* := (f^*, \phi^{-1}).$$

(6.2)

Since this definition involves the inverse of the morphism $\phi$ of $G$ it is important to assume that $G$ is a groupoid.

If $f$ is a unitary morphism in $A$, then $(f, \phi)$ is a unitary morphism in $A \times G$. If $A$ is a marked $*$-category, then in the $*$-category $A \times G$ we mark all morphisms of the form $(f, \phi)$ with $f$ marked in $A$ and $\phi$ in $G$ arbitrary.

For $\mathcal{C}$ in the list $\{\mathbb{C}^*\text{Cat}_1, \mathbb{C}^*\text{Cat}_1^+\}$ we thus have defined a functor
$$- \times - : \mathcal{C} \times \text{Grpd}_1 \to \mathcal{C}.$$

In the $\mathbb{C}$-linear case we must modify this construction. For a $\mathbb{C}$-linear $*$-category $A$ and a groupoid $G$ we define $A \otimes G$ to be the category with the objects of $A \times G$, and whose morphisms are given by the complex vector spaces
$$\text{Hom}_{A \otimes G}((a, g), (a', g')) := \bigoplus_{\phi \in \text{Hom}_G(g, g')} \text{Hom}_A(a, a'),$$

with the obvious $*$-operation and composition. Note that the sum over an empty index set is the zero vector space.

We note that $A \times G$ is a wide subcategory of $A \otimes G$ in a natural way. If $A$ is marked, then in $A \otimes G$ we again mark all morphisms of the form $(f, \phi)$ for $f$ a marked morphism in $A$ and an arbitrary morphism $\phi$ of $G$.

For $\mathcal{C}$ in the list $\{\mathbb{C}^*\text{Cat}_1, \mathbb{C}^*\text{Cat}_1^+\}$ we thus have defined a functor
$$- \times - : \mathcal{C} \times \text{Grpd}_1 \to \mathcal{C}.$$

26
Example 6.10. If $A$ is a (marked) $\ast$-category, then we have an isomorphism

$$\text{Lin}_C(A) \otimes G \cong \text{Lin}_C(A \times G).$$

Example 6.11. If $G = BH$ for some group $H$, then the $\mathbb{C}$-linear $\ast$-category $\Delta^0_{\ast \mathbb{C}\text{-Cat}} \otimes BH$ is isomorphic to the $\mathbb{C}$-linear $\ast$-category associated to the group ring $\mathbb{C}[H]$ with its usual involution.

Let $G$ be a groupoid.

Lemma 6.12. If $A$ is a (marked) pre-$C^\ast$-category, then so is $A \otimes G$.

Proof. It suffices to show that

$$A \otimes G = \text{Bd}^\infty(A \otimes G). \quad (6.3)$$

Every morphism in $A \otimes G$ is a finite linear combination of morphisms of the form $(f, \phi)$ of $A \times G$ with $f : a \to a'$ and $\phi : g \to g'$. We can decompose $(f, \phi) = (\text{id}_{a'}, \phi) \circ (f, \text{id}_g)$.

Let $\rho : A \otimes G \to B$ be a representation in a $C^\ast$-algebra $B$. Then we can restrict $\rho$ to a representation of $A \cong A \times \{g\} \subseteq A \otimes G$. We conclude that $\|\rho(f, \text{id}_g)\|_B \leq \|f\|_{\text{max}}$, where $\|\cdot\|_{\text{max}}$ denotes the maximal norm on $A$. Furthermore, because of (6.2) we know that $\rho(\text{id}_{a'}, g)$ is a partial isometry in $B$. Therefore $\|\rho(f, \phi)\|_B \leq \|f\|_{\text{max}}$. This shows that $(f, g) \in \text{Bd}^\infty(A \otimes G)$. Hence also all finite linear combinations of such elements belong to $\text{Bd}^\infty(A \otimes G)$. This shows the desired equality (6.3).

For $C$ in the list $\{C^\ast_{\text{pre}\mathbb{C}\text{-Cat}_1}, C^\ast_{\text{pre}\mathbb{C}\text{-Cat}_1^+}\}$ we thus have defined a functor

$$- \otimes - : C \times \text{Grpd}_1 \to C.$$  

For a (marked) $\mathbb{C}$-linear $\ast$-category $A$ and a groupoid $G$ we define

$$A \otimes_{\text{max}} G := \text{Compl}(\text{Bd}^\infty(A \otimes G)).$$

If $A$ was a (marked) pre-$C^\ast$-category, then by Lemma 6.12 we can simplify this to

$$A \otimes_{\text{max}} G \cong \text{Compl}(A \otimes G).$$

For $C$ in the list $\{C^\ast\mathbb{C}\text{-Cat}_1, C^\ast\mathbb{C}\text{-Cat}_1^+\}$ we thus have defined a functor

$$- \otimes_{\text{max}} - : C \times \text{Grpd}_1 \to C.$$  

Example 6.13. We consider the $C^\ast$-category $\Delta^0_{C^\ast\mathbb{C}\text{-Cat}_1}$ associated to the $C^\ast$-algebra $\mathbb{C}$. For a groupoid $G$ the $C^\ast$-category $\Delta^0_{C^\ast\mathbb{C}\text{-Cat}_1} \otimes_{\text{max}} G$ is the maximal groupoid $C^\ast$-category. In particular, if $G = BH$ for a group $H$, then $\Delta^0_{C^\ast\mathbb{C}\text{-Cat}_1} \otimes_{\text{max}} BH$ is isomorphic to the $C^\ast$-category associated to the maximal group $C^\ast$-algebra $C^\ast_{\text{max}}(H)$.
Table 1:

| Case                     | # | ? |
|--------------------------|---|---|
| $^\ast\text{Cat}_1^{(+)}$ | $\times$ | $u$ |
| $^\ast\mathcal{C}\text{Cat}_1^{(+)}$ | $\otimes$ | $u$ |
| $C^\ast\text{pre}\text{Cat}_1^{(+)}$ | $\otimes$ | $bd$ |
| $C^\ast\text{Cat}_1^{(+)}$ | $\otimes_{\text{max}}$ | $C^\ast$ |

**Convention 6.14.** In order to avoid a case-dependent notation we write $\#$ for the tensor structures with groupoids $\times$, $\otimes$, or $\otimes_{\text{max}}$ in the respective cases. We will furthermore use the notation $\mathcal{F}\text{un}^?$, where $?$ is $u$, $bd$, or $C^\ast$ in the respective cases. See Table 1.

**Example 6.15.** Let $\mathcal{C}$ be in the list

\[ \{^\ast\text{Cat}_1, ^\ast\mathcal{C}\text{Cat}_1, C^\ast\text{pre}\text{Cat}_1, C^\ast\text{Cat}_1, ^\ast\mathcal{C}\text{Cat}_1^{+}, C^\ast\text{pre}\text{Cat}_1^{+}, C^\ast\text{Cat}_1^{+}\} \]

and recall the morphism classifier object $\mathbb{I}$ in $\text{Grpd}_1$ from Definition 4.14. Let $f_0, f_1 : \mathcal{C} \to \mathcal{D}$ two morphisms in $\mathcal{C}$. Then we have a bijective correspondence between (marked) unitary isomorphisms $u : f_0 \to f_1$ and functors $U : C^\ast\mathbb{I} \to \mathcal{D}$ with $U \circ \iota_1 = f_1$, where $\iota_1 : \mathcal{C} \cong C^\ast\Delta^0 \to C^\ast\mathbb{I}$ for $i = 0, 1$ is induced by the objects 0 and 1 of $\mathbb{I}$. Given $U$, the (marked) unitary isomorphism $u$ is obtained by $u = (U(\text{id}_c, 0 \to 1))_{c \in \mathcal{C}}$. Vice versa, given $u$, we can define $U$ on morphisms by $U(\text{id}_c, 0 \to 1) = u_b$ and $U(a, \text{id}_0) := f_0(a)$ and compatibility with compositions and $\ast$.

Let $\mathcal{G}$ be a groupoid and $\mathcal{C}$ be in the list

\[ \{^\ast\text{Cat}_1, ^\ast\mathcal{C}\text{Cat}_1, C^\ast\text{pre}\text{Cat}_1, C^\ast\text{Cat}_1, ^\ast\mathcal{C}\text{Cat}_1^{+}, C^\ast\text{pre}\text{Cat}_1^{+}, C^\ast\text{Cat}_1^{+}\} \].

**Proposition 6.16.** For $\mathcal{C}$ and $\mathcal{A}$ in $\mathcal{C}$ we have a natural exponential law

\[ \text{Hom}_{\mathcal{C}}(C^\ast\mathcal{G}, \mathcal{A}) \cong \text{Hom}_{\mathcal{C}}(\mathcal{C}, \mathcal{F}\text{un}^?(\mathcal{G}, \mathcal{A})) \].

**Proof.** We start with giving the natural bijection in the case of $\ast$-categories. Let $\Phi$ be in $\text{Hom}_{\text{Cat}_1}(\mathcal{C} \times \mathcal{G}, \mathcal{A})$. The bijection identifies this morphism with a morphism $\Psi$ in $\text{Hom}_{\text{Cat}_1}(\mathcal{C}, \mathcal{F}\text{un}^?(\mathcal{G}, \mathcal{A}))$ given by

\[ \Psi(c)(g) := \Phi(c, g) , \quad \Psi(c)(\phi) := \Phi(\text{id}_c, \phi) , \quad \Psi(f) := (\Phi(f, \text{id}_g)_{g \in \mathcal{G}}) . \]

Here $c$ is an object of $\mathcal{C}$, $g$ is an object of $\mathcal{G}$, $\phi$ is a morphism in $\mathcal{G}$, and $f$ is a morphism in $\mathcal{C}$. Note that $\Psi(c)$ takes values in unitary functors since

\[ \Psi(c)(\phi)^* = \Phi(\text{id}_c, \phi)^* = \Phi(\text{id}_c, \phi^*) = \Phi(\text{id}_c, \phi^{-1}) = \Psi(c)(\phi)^{-1} . \]
Vice versa let the morphism $\Psi$ be given. Then the bijection sends it to the morphism $\Phi$ given by

$$\Phi(c, g) := \Psi(c)(g), \quad \Phi(f, \phi) := \Psi(c')(\phi) \circ \Psi(f)(g),$$

where $f : c \to c'$ is a morphism in $C$ and $\phi : g \to g'$ is a morphism in $G$.

The same formulas work in the $\mathbb{C}$-linear case for morphisms of the form $(f, \phi)$. The maps are then extended linearly. In the case of pre-$C^*$-categories we must check that $\Psi$ takes values in the subfunctor $\mathcal{F}un^{bd}(G, A)$ of $\mathcal{F}un^u(G, A)$. But this is clear since $\Psi$ is a morphism between $\mathbb{C}$-linear categories, $C$ is a pre-$C^*$-category, and the universal property of $\underline{\text{Bd}}^\infty_\odd.

We finally consider the case of $C^*$-categories. In this case we could cite [Del10]. Here is the argument. We first observe that for a $C^*$-category $A$ and pre-$C^*$-category $C$ we have a bijection

$$\text{Hom}_{C_{pre}^{\ast}\text{-Cat}^1}(C \otimes G, \mathcal{F}_-(A)) \cong \text{Hom}_{C^*\text{-Cat}^1}(C \otimes_{\text{max}} G, A)$$

(6.4)

by the universal property of the completion. We can use this bijection, the already verified bijection

$$\text{Hom}_{C_{pre}^{\ast}\text{-Cat}^1}(C \otimes G, \mathcal{F}_-(A)) \cong \text{Hom}_{C_{pre}^{\ast}\text{-Cat}^1}(C, \mathcal{F}un^{bd}(G, \mathcal{F}_-(A))),$$

and the completion map

$$\text{Hom}_{C_{pre}^{\ast}\text{-Cat}^1}(C, \mathcal{F}un^{bd}(G, \mathcal{F}_-(A))) \to \text{Hom}_{C_{pre}^{\ast}\text{-Cat}^1}(C, \mathcal{F}_-(\mathcal{F}un^{C^*}(G, A)))$$

(6.5)

in order to produce a $\Psi$ from a given $\Phi$.

For the inverse we note that since $A$ is complete, the evaluation functors

$$e_g : \mathcal{F}un^{bd}(G, \mathcal{F}_-(A)) \to A$$

for $g$ in $G$ extend to the completion and provide functors

$$\bar{e}_g : \mathcal{F}un^{C^*}(G, A) \to A.$$

Hence the formula which expresses $\Phi$ in terms of $\Psi$ makes sense. It defines, by linear extension, an element in $\text{Hom}_{C_{pre}^{\ast}\text{-Cat}^1}(C \otimes G, \mathcal{F}_-(A))$ which gives the desired $\Phi$ in $\text{Hom}_{C^*\text{-Cat}^1}(C \otimes_{\text{max}} G, A)$ using the isomorphism (6.4) above.

In the marked case we just observe the following. If $\Phi$ is a functor between marked categories, then $\Psi$ takes values in marked functors, and vice versa, if $\Psi$ has this property, then $\Phi$ preserves marked morphisms.

Let $G$ be a groupoid.

**Corollary 6.17.** If $A$ is a (marked) $C^*$-category, then the completion morphism

$$\mathcal{F}un^{bd}(G, \mathcal{F}_-(A)) \to \mathcal{F}_-(\mathcal{F}un^{C^*}(G, A))$$

is an isomorphism and $\mathcal{F}un^{bd}(G, A)$ is a (marked) $C^*$-category.
Proof. In the proof of Proposition 6.16 we have actually shown that for every pre-$C^*$-category $C$ there is a natural isomorphism

$$\text{Hom}_{C^* \text{pre} \text{Cat}}(C \otimes_{\text{max}} G, \mathcal{F}_-(A)) \cong \text{Hom}_{C^* \text{pre} \text{Cat}}(C, \mathcal{F}_-(\text{Fun}^C(G, A))).$$

Furthermore we have a natural isomorphism

$$\text{Hom}_{C^* \text{pre} \text{Cat}}(C \otimes_{\text{max}} G, A) \cong \text{Hom}_{C^* \text{pre} \text{Cat}}(C, \text{Fun}^{bd}(G, A)).$$

By an inspection of the construction of these bijections we see that the resulting isomorphism

$$\text{Hom}_{C^* \text{pre} \text{Cat}}(\sim, \text{Fun}^{bd}(G, A)) \cong \text{Hom}_{C^* \text{pre} \text{Cat}}(\sim, \text{Fun}^C(G, A)).$$

of functors $C^* \text{pre} \text{Cat}^\text{op} \to \text{Set}$ is induced by the completion morphisms

$$\text{Fun}^{bd}(G, A) \to \text{Fun}^C(G, A).$$

By the Yoneda Lemma it is therefore an isomorphism, too. \hfill \square

In the following we introduce the fundamental groupoid functor $\Pi : \text{sSet} \to \text{Grpd}_1$.

**Definition 6.18.** The fundamental groupoid functor is defined as a left-adjoint of an adjunction

$$\Pi : \text{sSet} \rightleftarrows \text{Grpd}_1 : \mathbb{N},$$

where $\mathbb{N}$ takes the nerve of a groupoid.

Explicitly, the fundamental groupoid $\Pi(K)$ of a simplicial set $K$ is the groupoid freely generated by the path category $P(K)$ of $K$. The category $P(K)$ in turn is given as follows:

1. The objects of $P(K)$ are the 0-simplices.

2. The morphisms of $P(K)$ are generated by the 1-simplices of $K$ subject to the relation $g \circ f \sim h$ if there exists a 2-simplex $\sigma$ in $K$ with $d_2 \sigma = f$, $d_0 \sigma = g$ and $d_1 \sigma = h$.

In the following definition we use the notation introduced in Convention 6.14. Let $C$ be a member of the list

$$\{^*\text{Cat}_1, ^*_{\mathbb{C}}\text{Cat}_1, C^* \text{pre} \text{Cat}_1, C^* \text{Cat}_1, ^*_{\mathbb{C}}\text{Cat}_1, C^* \text{pre} \text{Cat}_1, C^* \text{Cat}_1 \}.$$

**Definition 6.19.** We define the tensor and cotensor structure of $C$ with $\text{sSet}$ by

$$C \times \text{sSet} \to C, \quad (A, K) \mapsto A^\# K := A^\# \Pi(K)$$

and

$$\text{sSet}^{\text{op}} \times C \to C, \quad (K, B) \mapsto B^K := \text{Fun}^\gamma(\Pi(K), B).$$

For objects $A, B$ of $C$ we define the simplicial mapping space $\text{Map}(A, B)$ in $\text{sSet}$ by

$$\text{Map}(A, B)[\sim] := \text{Map}(A^\# \Delta^-, B).$$

Then for every two objects $A, B$ in $C$ and every simplicial set $K$, by Proposition 6.16 we have natural bijections

$$\text{Hom}_{\text{Set}}(K, \text{Map}(A, B)) \cong \text{Hom}_C(A^\# K, B) \cong \text{Hom}_C(A, B^K). \quad (6.6)$$

In this way we have defined a simplicial enrichment of $C$. 

30
7 The resolution

Let \( G \) be a group. In the present section we consider the functor categories from a particular \( G \)-groupoid \( \tilde{G} \). These functor categories will serve as explicit fibrant resolutions later in Section 13.

**Definition 7.1.** We define the \( G \)-groupoid \( \tilde{G} \) as follows:

1. The set of objects of \( \tilde{G} \) is the underlying set of \( G \).
2. For every pair of objects \( g, h \) of \( \tilde{G} \) the set of morphisms \( \text{Hom}_{\tilde{G}}(g, h) \) consists of one point which we will denote by \( g \to h \). The composition of morphisms is defined in the only possible way.
3. The group \( G \) acts on the groupoid \( \tilde{G} \) by left multiplication.

In other symbols, in Definition 7.1 we have described an object \( \tilde{G} \) of \( \text{Fun}(BG, \text{Grpd}_1) \).

For a \( G \)-category \( A \) we consider the functor category \( \text{Fun}(\tilde{G}, A) \) again as a \( G \)-category. The group \( G \) acts on this functor category as follows. If \( a : \tilde{G} \to A \) is a functor, then we set \( g(a) := g \circ a \circ g^{-1} \). The action on morphisms is similar. We interpret this construction as a functor

\[
\text{Fun}(\tilde{G}, -) : \text{Fun}(BG, \text{Cat}_1) \to \text{Fun}(BG, \text{Cat}_1).
\]

This construction extends to the various versions of (marked) \( * \)-categories. For \( C \) in the list

\[
\{ *\text{Cat}_1, *\_\text{Cat}_1, C^*\text{Cat}_1, C^*_\text{Cat}_1, *\_\text{Cat}_1^+, C^*_\text{Cat}_1^+, C^*_\text{Cat}_1^+ \}
\]

we get a functor

\[
\text{Fun}^*(\tilde{G}, -) : C \to C,
\]

see Convention 6.14 for notation.

**Lemma 7.2.** If \( A \) is a (marked) pre-\( C^* \)-category, then the natural morphism

\[
\text{Fun}^{bd}(\tilde{G}, A) \to \text{Fun}^u(\tilde{G}, A)
\]

is an isomorphism of (marked) \( C \)-linear \( * \)-categories.

**Proof.** We must show that every morphism in \( \text{Fun}^u(\tilde{G}, A) \) has a finite maximal norm. If \( a \) is a unitary functor from \( \tilde{G} \) to \( A \), then we have a unitary isomorphism

\[
h_a := (a(1 \to g))_{g \in \tilde{G}} : \text{const}(a(1)) \to a,
\]

where \( \text{const}(a(1)) \) denotes the constant functor with value \( a(1) \). Unitarity implies the norm estimates \( \|h_a\|_{\text{max}} \leq 1 \) and \( \|h_a^{-1}\|_{\text{max}} \leq 1 \), see Remark 4.8.

If \( f : a \to a' \) is a morphism in \( \text{Fun}^u(\tilde{G}, A) \), then we have the relation

\[
h_{a'} \circ \text{const}(f(1)) \circ h_a^{-1} = f.
\]
This implies the inequality
\[ \|f\|_{\text{max}} \leq \|\text{const}(f(1))\|_{\text{max}} \leq \|f(1)\|_{\text{max}} . \]

Using Corollary 6.17 we conclude:

**Corollary 7.3.** For a (marked) $C^*$-category $A$ the natural maps are isomorphisms
\[ \mathcal{F}un^{C^*}(\tilde{G}, A) \cong \mathcal{F}un^{bd}(\tilde{G}, A) \cong \mathcal{F}un^{u}(\tilde{G}, A) \]
isomorphism of (marked) $\mathbb{C}$-linear $*$-categories.

**Remark 7.4.** In view of Corollary 7.3 and Lemma 7.2 we have an isomorphism of (marked) $\mathbb{C}$-linear $*$-categories.
\[ \mathcal{F}un^u(\tilde{G}, A) \cong \mathcal{F}un^u(\tilde{G}, A) \]
in all cases, see Convention 6.14 and Remark 6.2 for the usage of notation.

We have a $G$-equivariant version of the exponential law. Let $\mathcal{C}$ be in the list
\[ \{ \ast \text{Cat}, \ast_{\mathcal{C}} \text{Cat}, C_{\text{pre}} \ast \text{Cat}, C^* \ast \text{Cat}, C^*_{\text{pre}} \ast \text{Cat}, C^+ \ast \mathcal{C} \ast \text{Cat}, C^+_{\text{pre}} \ast \text{Cat} \} . \]

**Proposition 7.5.** For $A$ and $C$ in $\mathcal{F}un(BG, \mathcal{C})$ we have a natural isomorphism
\[ \hom_{\mathcal{F}un(BG, \mathcal{C})}(\ast_{\mathcal{C}} \tilde{G}, A) \cong \hom_{\mathcal{F}un(BG, \mathcal{C})}(C, \mathcal{F}un^u(\tilde{G}, A)) . \]

**Proof.** This follows from an inspection of the proof of Proposition 6.16.

## 8 Completeness and cocompleteness

The goal of this section is to show the following theorem.

**Theorem 8.1.** The categories in the list
\[ \{ \ast \text{Cat}, \ast_{\mathcal{C}} \text{Cat}, C^*_{\text{pre}} \ast \text{Cat}, C^* \ast \text{Cat}, C^+_{\text{pre}} \ast \text{Cat}, C^+ \ast \text{Cat} \} \]
are complete and cocomplete.

**Remark 8.2.** The case of $C^*$-categories is due to [Del10]. For completeness of the presentation we reprove this case together with the others.
Remark 8.3. In the proof we use that the categories of categories and marked categories
\( \text{Cat}_1 \) and \( \text{Cat}_1^+ \) are complete and cocomplete. In particular we must understand colimits
in \( \text{Cat}_1 \) in some detail. Let \( \text{DirGraph} \) denote the category of directed graphs. Then we
have an adjunction
\[
\text{Free}_{\text{Cat}} : \text{DirGraph} \rightleftarrows \text{Cat}_1 : F_0 ,
\] 
where \( F_0 \) sends a category to its underlying directed graph (i.e., forgets the composition),
and \( \text{Free}_{\text{Cat}} \) sends a directed graph to the category freely generated by it. Colimits in
\( \text{DirGraph} \) are formed by taking the colimits of the sets of vertices and edges separately.

If \( C \) is a category, then the counit of the adjunction (8.1) provides a functor
\[
\text{Free}_{\text{Cat}}(F_0(C)) \rightarrow C .
\] 
It is a bijection on objects. We \( R(C) \) denote the equivalence relation on the morphisms of
\( \text{Free}_{\text{Cat}}(F_0(C)) \) generated by the action of the functor (8.2) on morphisms. This relation
is compatible with the category structure and the functor (8.2) induces an isomorphism
\[
\text{Free}_{\text{Cat}}(F_0(C))/R(C) \cong C .
\]

We now consider a diagram \( A : I \rightarrow \text{Cat}_1 \). Then we form the category \( \text{Free}_{\text{Cat}}(\lim_i F_0(A)) \). On the morphisms of this category we consider the smallest equivalence relation \( R \) compatible
with the category structure which contains the images of \( R(A(i)) \) under the canonical maps
\[
\text{Mor}(\text{Free}_{\text{Cat}}(F_0(A(i)))) \rightarrow \text{Mor}(\text{Free}_{\text{Cat}}(\lim_i F_0(A)))
\]
for all \( i \) in \( I \). Then one can check that
\[
\text{Free}_{\text{Cat}}(\lim_i F_0(A))/R \cong \lim_i A .
\]

We will in particular need the following conclusion of this discussion: Every morphism
in \( \lim_i A \) is a finite composition of morphisms of the form \( u_i(f_i) \) where, for \( i \) in \( I \),
\( u_i : A(i) \rightarrow \lim_i A \) is the canonical functor and \( f_i \) is in \( \text{Mor}(A(i)) \).

Proof. (of Theorem 8.1) We first show completeness. Our starting point is the fact that
the 1-category \( \text{Cat}_1 \) is complete. If \( A : I \rightarrow \text{Cat}_1 \) is a diagram of categories, then we
have canonical isomorphisms of sets
\[
\text{Ob}(\lim_i A) \cong \lim_i \text{Ob}(A), \quad \text{Mor}(\lim_i A) \cong \lim_i \text{Mor}(A) .
\]
Next we consider \( \ast \text{Cat}_1 \). Because of the adjunction (8.1) a limit in \( \ast \text{Cat}_1 \) (provided it exists)
can be calculated as follows. One first calculates the limit in \( \text{Cat}_1 \) (i.e., after forgetting the \( \ast \)-operation), and then restores the \( \ast \)-operation using the functoriality
of the limit. Thus let \( A : I \rightarrow \ast \text{Cat}_1 \) be a diagram. We choose a category \( B \) together
with a morphism \( \text{const}(B) \rightarrow F_0(A) \) which exhibits \( B \) as a representative of the limit
\( \lim_i F_0(A) \) . Then we can take \( B^{\text{op}} \) and \( \text{const}(B)^{\text{op}} \rightarrow F_0(A)^{\text{op}} \) in order to exhibit the
limit \( \lim_I F_s(A)^{op} \). The transformation \( * : F_s(A) \to F_s(A)^{op} \) now determines a unique functor \( * : B \to B^{op} \) such that

\[
\begin{array}{ccc}
const(B) & \xrightarrow{\text{const}(*)} & const(B)^{op} \\
\downarrow & & \downarrow \\
F_s(A) & \xrightarrow{*} & F_s(A)^{op}
\end{array}
\]

commutes. This functor is the identity on objects and turns \( B \) into a \( * \)-category. Together with the morphism of diagrams of \( * \)-categories \( \text{const}(B) \to A \) it represents the limit \( \lim_I A \) in \( *\text{Cat}_1 \).

In order to deal with the marked case we observe that \( \text{Cat}_1^+ \) is complete. If \( A : I \to \text{Cat}_1^+ \) is a diagram of marked categories, then in order to construct the marked category \( \lim_I A \), using the forgetful functor \( F_+ \) from (3.7) we form the category \( \lim_I F_+(A) \) and mark the morphisms which are the elements of \( \text{Mor}(\lim_I F_+(A)) \) whose evaluation (use (8.3)) at all objects \( i \) of \( I \) are marked. We can now repeat the constructions above with \( A \) and \( B \) marked.

The same idea works for a diagram \( A : I \to *\text{Cat}_1 \) of \( C \)-linear \( * \)-categories. Since the forgetful functor \( F_C \) from (3.2) is the right-adjoint of the adjunction it preserves limits. Hence we have

\[ F_C(\lim_I A) \cong \lim_I F_C(A) \]

if the limit on the left-hand side exists. The limit on the right-hand side is interpreted in \( *\text{Cat}_1 \) and exists as we have seen above. In the following we argue that limit on the left-hand side indeed exists. For a diagram \( A : I \to *\text{Cat}_1 \) we first define the object \( \lim_I F_C(A) \) in \( *\text{Cat}_1 \), then observe that the limit has an induced complex enrichment. We then observe that the canonical morphism

\[ \text{const}(\lim_I F_C(A)) \to A \]

is compatible with the enrichment and exhibits the \( * \)-category \( \lim_I F_C(A) \) together with the enrichment as the limit \( \lim_I A \).

The same argument applies in the marked case.

Let \( F_{pre} \) and \( \text{Bd}^\infty \) be the functors as in (3.6). For a diagram of pre-\( C^* \)-categories \( A : I \to C^*_\text{pre}\text{Cat}_1 \) we have an isomorphism

\[ \lim_I A \cong \text{Bd}^\infty(\lim_I F_{pre}(A)) \], \quad (8.4) \]

where the limit on the right-hand side is interpreted in \( *\text{Cat}_1 \). This immediately follows from the adjunction (3.6) since \( F_{pre} \) is a fully faithful inclusion. The same argument applies in the marked case.

Let \( F_- \) be the forgetful functor from (3.3). Since it is the right-adjoint of an adjunction it is clear that it preserves limits. We consider a diagram of \( C^* \)-categories \( A : I \to C^*\text{Cat}_1 \). Then we have

\[ F_-(\lim_I A) \cong \lim_I F_-(A) \]
if the limit $\lim_I A$ exists. The limit on the right-hand side is interpreted in $C^\ast_{\pre} \text{Cat}_1$ and exists as seen above. We now argue that the limit on the left-hand side indeed exists. Every limit can be expressed as a finite combination of equalizers and products. It therefore suffices to show that $\lim_I \mathcal{F}_-(A)$ is a $C^\ast$-category in the case that $I$ is a set or a finite category.

If $I$ is a set, then the limit is represented by the bounded product

$$\lim_I A \cong \prod_{i \in I} A(i).$$

Indeed, this product has the universal property since morphisms between $C^\ast$-categories are norm-bounded by 1.

If $I$ is finite, then we realize $\lim_I A$ as a subcategory of $\prod_I A(i)$ cut out by linear $\ast$-invariant continuous equations. This is again $C^\ast$-category.

We now consider the marked case. If $A: I \to C^\ast \text{Cat}_1^+$ is a diagram of marked $C^\ast$-categories, then $\lim_I \mathcal{F}_-(A)$ is a marked pre-$C^\ast$-category. Above we have seen that it is also a marked $C^\ast$-category which then necessarily represents $\lim_I A$.

This finishes the proof of completeness in all cases.

We now show cocompleteness.

We start with the cocompleteness of $\ast \text{Cat}_1$. In the argument we employ the fact that $\text{Cat}_1$ is cocomplete, see Remark 3.3. Let $A: I \to \ast \text{Cat}_1$ be a diagram. Then we choose a category $B$ together with a morphism $\mathcal{F}_+(A) \to \text{const}(B)$ which exhibits $B$ as a colimit $\text{colim}_I \mathcal{F}_+(A)$, where $\mathcal{F}_+$ is as in (3.2). Then we can take $B^{\text{op}}$ and $\mathcal{F}_+(A)^{\text{op}} \to \text{const}(B)^{\text{op}}$ as a representative of the colimit $\text{colim}_I \mathcal{F}_+(A)^{\text{op}}$. Similarly as in the case of limits, the transformation $\ast: \mathcal{F}_+(A) \to \mathcal{F}_+(A)^{\text{op}}$ now induces a functor $\ast: B \to B^{\text{op}}$ in the canonical way such that it is the identity on objects. Hence $B$ has the structure of a $\ast$-category. The canonical morphism of diagrams of $\ast$-categories $A \to \text{const}(B)$ exhibits $B$ as the colimit $\text{colim}_I A$.

In the marked case we use that we have already shown that $\ast \text{Cat}_1$ is cocomplete. If $A: I \to \ast \text{Cat}_1^+$ is a diagram, then in order to construct the marked $\ast$-category $\text{colim}_I A$ we first form the $\ast$-category $B := \text{colim}_I \mathcal{F}_+(A)$, where $\mathcal{F}_+$ is as in (3.7). In $B$ we mark all morphisms which are compositions of morphisms of the form $u_i(f_i)$ for $i$ in $I$, a marked morphism $f_i$ in $A(i)$, and where $u_i: \mathcal{F}_+(A(i)) \to \text{colim}_I \mathcal{F}_+(A) = B$ is the canonical $\ast$-functor. Since $u_i$ is a $\ast$-functor we have for a marked $f_i$ that

$$u_i(f_i^*) = u_i(f_i^{-1}) = u_i(f_i)^{-1}.$$  

This implies that the marked morphisms in $B$ are unitary. By construction they are closed under composition so that $B$ is a marked $\ast$-category, and $A \to \text{const}(B)$ is a morphism of diagrams of marked $\ast$-categories. It exhibits $B$ as the colimit $\text{colim}_I A$ in $\ast \text{Cat}_1^+$.
In order to construct colimits in \( \mathbf{Cat}_1 \) we use the adjunction \((3.2)\). If \( C \) is a \( \mathbb{C} \)-linear \( * \)-category, then we have a natural exact sequence of \( \mathbb{C} \)-linear \( * \)-categories

\[
0 \to R(C) \to \text{Lin}_C(\mathcal{F}_C(C)) \to C \to 0,
\]

with the caveat that \( R(C) \) is non-unital. The second map in this sequence is the counit of the adjunction \((3.2)\). For a diagram \( A : I \to \mathbf{Cat}_1 \) we now define \( B \) as the quotient

\[
0 \to \langle R(A(i)) \mid i \in I \rangle \to \text{Lin}_C(\colim_I \mathcal{F}_C(A)) \to B \to 0,
\]

where \( \langle R(A(i)) \mid i \in I \rangle \) is the non-unital \( \mathbb{C} \)-linear \( * \)-subcategory of \( \text{Lin}_C(\colim_I \mathcal{F}_C(A)) \) generated as an ideal by the images of \( R(A(i)) \) for all \( i \in I \). By construction for every \( i \in I \) we have a canonical factorization

\[
\xymatrix{
\text{Lin}_C(\mathcal{F}_C(A(i))) \ar[r] \ar[d] & \text{Lin}_C(\colim_I \mathcal{F}_C(A)) \ar[d] \\
A(i) \ar[r] & B
}
\]

In this way we get a morphism of diagrams \( A \to \text{const}(B) \). We now observe that this exhibits \( B \) as the colimit \( \text{colim} \ A \) in \( \mathbf{Cat}_1 \). Indeed, let \( C \) be in \( \mathbf{Cat}_1 \), and a morphism \( A \to \text{const}(C) \) of diagrams in \( \mathbf{Cat}_1 \) be given. Then we get a morphism

\[
\text{Lin}_C(\mathcal{F}_C(A)) \to \text{const}(C)
\]

in \( \mathbf{Cat} \) from the counit of the adjunction \((3.2)\). Hence we get a uniquely determined morphism

\[
\text{Lin}_C(\colim_I \mathcal{F}_C(A)) \to C
\]

since colimits in \( \mathbf{Cat}_1 \) exist and the left adjoint \( \text{Lin}_C \) preserves colimits. We finally see that this morphism, by definition of \( B \), uniquely factorizes over a morphism \( B \to C \).

In order to deal with the marked case we use the marked version of the adjunction \((3.2)\) and argue in a similar manner using that we have shown above that \( \mathbf{Cat}_1^* \) is cocomplete.

We now consider colimits in \( C^*_p \mathbf{Cat}_1 \). The inclusion functor \( \mathcal{F}_{\text{pre}} \) is the left-adjoint of the adjunction \((3.0)\). Consequently it preserves colimits. It therefore suffices to show that if \( A : I \to C^*_p \mathbf{Cat}_1 \) is a diagram of pre-\( C^* \)-categories, then the \( \mathbb{C} \)-linear \( * \)-category \( \colim_I \mathcal{F}_{\text{pre}}(A) \) is in fact a pre-\( C^* \)-category. Let \( f \) be a morphism in \( \colim_I \mathcal{F}_{\text{pre}}(A) \). We must show that \( \|f\|_{\text{max}} \) is finite. By the description of colimits in \( \mathbf{Cat}_1 \) given in Remark \((8.3)\) and by the construction of colimits in \( \mathbf{Cat}_1^* \), \( \mathbf{Cat}_1^* \) given above, the morphism \( f \) is equal to a finite linear combinations of finite compositions morphisms of the form \( u_i(f_i) \), where \( f_i \) belongs to \( \mathcal{F}_{\text{pre}}(A(i)) \) and \( u_i : \mathcal{F}_{\text{pre}}(A(i)) \to \colim_I \mathcal{F}_{\text{pre}}(A) \) is the canonical morphism. Hence we can assume that \( f = u_i(f_i) \). If \( \rho \) is a representation of \( \colim_I \mathcal{F}_{\text{pre}}(A) \) into a \( C^* \)-algebra \( B \), then \( \rho \circ u_i \) is a representation of \( \mathcal{F}_{\text{pre}}(A(i)) \). It follows that \( \|\rho(f)\|_B \leq \|\rho(u_i(f_i))\|_B \leq \|f_i\|_{\text{max}} \).

The same argument applies in the marked case.
If $A : I \to C^{\ast}\text{Cat}_1^{(+)}$ is a diagram of (marked) $C^{\ast}$-categories, then we have an isomorphism
\[
\limcolim_i A \cong \text{Compl}(\limcolim \mathcal{F}_-(A)) , \tag{8.5}
\]
where the colimit on the right-hand side is interpreted in $C^{\ast}_{\text{pre}}\text{Cat}_1^{(+)}$ and exists as seen above. The isomorphism (8.5) follows immediately from the adjunction (3.4) since the forgetful functor $\mathcal{F}_-$ is fully faithful.

\section{Verification of the model category axioms}

Let $\mathcal{C}$ be a member of the list
\[
\{^{\ast}\text{Cat}_1, ^{\ast}_{\text{c}}\text{Cat}_1, C^{\ast}_{\text{pre}}\text{Cat}_1, C^{\ast}\text{Cat}_1, ^{\ast}_{\text{c}}\text{Cat}_1^{\ast}, C^{\ast}_{\text{pre}}\text{Cat}_1^{\ast}, C^{\ast}\text{Cat}_1^{\ast}\} . \tag{9.1}
\]
In this section we state the main theorem on the model category structures again. We first recall the description of cofibrations, fibrations and weak equivalences.

\begin{definition}
1. A weak equivalence in $\mathcal{C}$ is a (marked) unitary equivalence (see Definition 5.2).
2. A cofibration is a morphism in $\mathcal{C}$ which is injective on objects.
3. A fibration is a morphism in $\mathcal{C}$ which has the right-lifting property with respect to trivial cofibrations.
\end{definition}

In condition 1 and below the word \textit{marked} only applies to the four marked versions. In the marked case, by Lemma 5.3.1 a weak equivalence detects marked morphisms.

For the simplicial structure we refer to Definition 6.19.

\begin{theorem}
The structures described in Definition 9.1 and Definition 6.19 equip $\mathcal{C}$ with a simplicial model category structure.

If $\mathcal{C}$ is a member of $\{^{\ast}\text{Cat}_1, ^{\ast}_{\text{c}}\text{Cat}_1, C^{\ast}\text{Cat}_1, ^{\ast}_{\text{c}}\text{Cat}_1^{\ast}, C^{\ast}_{\text{pre}}\text{Cat}_1^{\ast}, C^{\ast}\text{Cat}_1^{\ast}\}$, then the model category is cofibrantly generated and combinatorial.
\end{theorem}

\begin{remark}
In the case of $\mathcal{C} = C^{\ast}\text{Cat}_1$ a proof of the first part of the theorem has been given in \cite{Del10}.
\end{remark}

\begin{remark}
It is a lack of suitable morphism classifier objects in the pre-$C^{\ast}$-category cases, which prevents us to show cofibrant generation in these cases, see also Remark 4.7.
\end{remark}
In the present section we show that the structures explained above determine a model category structure on \( \mathcal{C} \). The simplicial axioms will be verified in Section 10. Finally, the additional assertions on cofibrant generation and combinatoriality are shown in Section 11.

In the following we list the axioms (cf. [Hov99]) which we have to verify in order to show that \( \mathcal{C} \) with the structures given in Definition 9.1 is a model category:

1. ((co)completeness) Completeness and cocompleteness have been verified in Section 8.
2. (retracts) This is Proposition 9.12.
3. (2 out of 3) This is Lemma 9.11.
4. (lifting) This is Proposition 9.8 together with Corollary 9.9 and Proposition 9.10.
5. (factorization) This is shown in Proposition 9.13.

In Definition 9.1 we have characterized fibrations by the lifting property. In the following we explicitly define a set of morphisms called good morphisms for the moment. Later in Proposition 9.8 it will turn out that these are exactly the fibrations.

We consider a morphism \( a : \mathcal{C} \to \mathcal{D} \) in a category \( \mathcal{C} \) belonging to the list (9.1).

**Definition 9.5.** The morphism \( a \) is called good\(^6\), if for every object \( d \) of \( \mathcal{D} \) and unitary (marked) morphism \( u : a(c) \to d \) for some object \( c \) of \( \mathcal{C} \) there exists a unitary (marked) morphism \( v : c \to c' \) such that \( a(v) = u \).

Here the word *marked* only applies in the marked cases.

Let \( \Delta^0 \) in \( \mathcal{C} \) be the object classifier (Definition 4.2) and \( \mathbb{I} \) be the classifier of invertibles in \( \text{Cat}_1 \) (Definition 4.14). Note that \( \mathbb{I} \) is a groupoid.

**Remark 9.6.** In the unmarked case we have an isomorphism \( 1 \cong \Delta^0 \sharp \mathbb{I} \), where \( 1 \) is the unitary morphism classifier (Definition 4.10).

In the marked case we have \( 1^+ \cong \Delta^0 \sharp \mathbb{I} \), where \( 1^+ \) (Definition 4.12) classifies the marked morphisms.

Let \( \Delta^0 \to \Delta^0 \sharp \mathbb{I} \) classify the object 0. We consider a morphism \( a : \mathcal{C} \to \mathcal{D} \) as above.

**Lemma 9.7.** The morphism \( a \) is good if and only if it has the right lifting property with respect to

\[ \Delta^0 \to \Delta^0 \sharp \mathbb{I} \]

**Proof.** In view of the universal properties of \( \Delta^0 \) and \( \Delta^0 \sharp \mathbb{I} \) this is just a reformulation of Definition 9.5.

\(^6\)The analog of this notion in category theory is called an isofibration. So we could call these morphisms unitary or marked isofibrations, but these names are longer.
Proposition 9.8. The good morphisms in $\mathcal{C}$ have the right lifting property with respect to trivial cofibrations.

Proof. We consider a diagram

$$
\begin{array}{ccc}
A & \xrightarrow{\alpha} & C \\
\downarrow{\ell} & & \downarrow{f} \\
B & \xrightarrow{j} & D \\
\end{array}
$$

(9.2)

where $f$ is good and $i$ is a trivial cofibration. We can find a morphism $j : B \to A$ such that $j \circ i = \text{id}_A$, $i \circ j \circ i = i$, and such that there is a unitary (marked) equivalence $u : i \circ j \to \text{id}_B$ which in addition satisfies $u \circ i = \text{id}_i$.

On objects we define $\ell$ as follows: If $b$ is an object of $B$ such that $b = i(a)$ for some object $a$ of $A$, then we set $\ell(b) := \alpha(a)$. This makes the upper triangle commute. If $b$ is not in the image of $i$, then we get a (marked) unitary $\beta(u_b) : f(\alpha(j(b))) = \beta(i(i(b))) \to \beta(b)$. Using that $f$ is good we choose a (marked) unitary $v : \alpha(j(b)) \to c$ such that $f(v) = \beta(u_b)$. We then set $\ell(b) := c$. This makes the lower triangle commute.

We now define the lift $\ell$ on a morphism $\phi : b \to b'$. We distinguish four cases:

1. If $b$ and $b'$ are in the image of $i$, then (since $i$ is an equivalence) there exists a unique morphism $\psi$ in $A$ such that $i(\psi) = \phi$ and we set

$$
\ell(\phi) := \alpha(\psi) .
$$

This again makes the upper triangle commute.

2. If $b = i(a)$ and $b'$ is not in the image of $i$, then we let $v'$ and $c'$ be the choices as above made for $b'$. In this case we set

$$
\ell(\phi) = v' \circ \alpha(j(\phi)) .
$$

3. Similarly, if $b' = i(a')$ and $b$ is not in the image of $i$, then we set

$$
\ell(\phi) := \alpha(j(\phi)) \circ v^{-1} .
$$

4. Finally, if both $b$ and $b'$ do not belong to the image, then we set

$$
\ell(\phi) := v' \circ \alpha(j(\phi)) \circ v^{-1} .
$$

One can check that then the lower triangle commutes and that this really defines a functor. One further checks (using that the morphisms $v, v'$ are (marked) unitaries) that $\ell$ is a morphism of (marked) $\ast$-categories. Finally, if $\mathcal{C}$ is one of the $\mathbb{C}$-vector space enriched cases, then $\ell$ is a functor between (marked) $\mathbb{C}$-linear $\ast$-categories.

\footnote{Note that the argument in \cite[Lemma 4.10]{Del10} contains a mistake at this point. With the definition given there the lower triangle would not commute on the level of objects}
Corollary 9.9. The sets of good morphisms and the fibrations coincide.

Proof. Since $\Delta^0 \to \Delta^0 \sharp I$ is a trivial cofibration, by Lemma 9.7 the fibrations are contained in the good morphisms. By Proposition 9.8 every good morphism is a fibration. □

Proposition 9.10. The cofibrations in $C$ have the left-lifting property with respect to the good morphisms which are in addition weak equivalences.

Proof. We again consider a diagram (9.2). Since the map $i$ is injective on objects and the morphism $f$ is surjective on objects we can find a lift $\ell$ on the level objects. Let now $b, b'$ be objects in $B$. Since $f$ is fully faithful (see Lemma 5.3) we have a bijection

$$\text{Hom}_C(\ell(b), \ell(b')) \xrightarrow{\sim} \text{Hom}_D(\beta(b), \beta(b')) \xrightarrow{\sim} \text{Hom}_C(\ell(b), \ell(b')) .$$

We can therefore define $\ell$ on $\text{Hom}_B(b, b')$ by

$$\text{Hom}_B(b, b') \xrightarrow{\beta} \text{Hom}_D(\beta(b), \beta(b')) \xrightarrow{\sim} \text{Hom}_C(\ell(b), \ell(b')) .$$

The lower triangle commutes by construction. One can furthermore check that the upper triangle commutes. Finally one checks that this really defines a functor. Since $f$ detects marked morphisms the functor $\ell$ preserves them. One now checks that the functor $\ell$ is a morphism between (marked) $\ast$-categories. If $C$ is one of the $C$-vector space enriched cases, then obviously $\ell$ is enriched, too. □

Lemma 9.11. The weak equivalences in $C$ satisfy the two-out-of three axiom.

Proof. It is clear that the composition of weak equivalences is a weak equivalence. Assume that $f : A \to B$ and $g : B \to C$ are morphisms such that $f$ and $g \circ f$ are weak equivalences. Then we must show that $g$ is a weak equivalence. Let $m : B \to A$ and $n : C \to A$ inverse functors and $u : m \circ f \to \text{id}_A$ and $v : f \circ m \to \text{id}_B$ and $x : n \circ g \circ f \to \text{id}_A$ and $y : g \circ f \circ n \to \text{id}_C$ the corresponding unitary (marked) isomorphisms.

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\downarrow{m} & & \downarrow{g} \\
B & \xrightarrow{v} & C \\
\downarrow{h=f\circ n} & & \downarrow{y=g\circ f\circ n} \\
C & \xrightarrow{x=ngf} & A
\end{array}
\]

Then we consider the functor $h := f \circ n : C \to B$. We have unitary (marked) isomorphisms

$$h \circ g = f \circ n \circ g \xrightarrow{v^{-1}} f \circ n \circ g \circ f \circ m \xrightarrow{x} f \circ m v \quad \text{and}$$

and

$$g \circ h = g \circ f \circ n y \quad \text{in $C$.}$$

□
Proposition 9.12. The cofibrations, fibrations and weak equivalences are closed under retracts.

Proof. Since fibrations maps are characterized by a right lifting property they are closed under retracts. Cofibrations are closed under retracts since a retract diagram of categories induces a retract diagram on the level of sets of objects, and injectivity of maps between sets is closed under retracts.

We finally consider weak equivalences (compare [Del10, Lemma 4.9]). Consider a diagram

\[
\begin{array}{ccc}
A & \rightarrow & A' \\
\downarrow^f & & \downarrow^{f'} \\
B & \rightarrow & B'
\end{array}
\]

with \( p \circ i = \text{id}_A \) and \( q \circ j = \text{id}_B \) and where \( f' \) is a weak equivalence. Let \( g' : B' \rightarrow A' \) be an inverse of \( f' \) up to unitary (marked) isomorphism. Then \( p \circ g' \circ j : B \rightarrow A \) is an inverse of \( f \) up to unitary (marked) isomorphism. \( \square \)

Proposition 9.13. In the category \( \mathcal{C} \) we have functorial factorizations.

Proof. We use a functorial cylinder object in order to factorize a morphism as

\[
\text{trivial fibration} \circ \text{cofibration}.
\]

We use the notation Convention 6.14.

For a morphism \( a : A \rightarrow B \) in \( \mathcal{C} \) we define the cylinder object \( Z(a) \) as the push-out

\[
\begin{array}{ccc}
A & \rightarrow & B \\
\downarrow^{(1)} & & \downarrow^\beta \\
A \# \mathbb{I} & \rightarrow & Z(a)
\end{array}
\]

where \( (1) \) is induced by the inclusion of the object 1 in \( \mathbb{I} \). We have a morphism \( \text{pr} : \mathbb{I} \rightarrow pt \). Since \( a \circ \text{pr} \circ (1) = \text{id}_B \circ a \), using the universal property of the push-out we can extend the diagram to

\[
\begin{array}{ccc}
A & \rightarrow & B \\
\downarrow^{(1)} & & \downarrow^\beta \\
A \# \mathbb{I} & \rightarrow & Z(a)
\end{array}
\]
We finally extend the diagram as follows

![Diagram](attachment:diagram.png)

using that $a \circ \text{pr} \circ (0) = a$ and setting $j := a' \circ (0)$.

We claim that $j$ is a cofibration and $q$ is a trivial fibration. In order to see these properties it is useful to calculate an explicit model $\tilde{Z}(a)$ for $Z(a)$.

We define $\tilde{Z}(a)$ as follows:

1. $\text{Ob}(\tilde{Z}(a)) := \text{Ob}(A) \sqcup \text{Ob}(B)$.
2. $\text{Hom}_{\tilde{Z}(a)}(x,y) := \begin{cases} 
\text{Hom}_A(x,y) & x, y \in A \\
\text{Hom}_B(a(x),y) & x \in A, y \in B \\
\text{Hom}_B(x,a(y)) & x \in B, y \in A \\
\text{Hom}_B(x,y) & x, y \in B
\end{cases}$.
3. The composition is defined in the only possible way.
4. The $*$-operation is induced by the $*$-operations on $A$ and $B$ in the canonical way.
5. The $\mathcal{C}$ enrichment of $A$ and $B$ induces an enrichment of $\tilde{Z}(a)$.
6. In the marked cases we mark all morphisms which are marked in $A$ or $B$.

We have defined $\tilde{Z}(a)$ as an object of $\ast\text{Cat}_1^{(+)}$ or $\ast\mathcal{C}\text{Cat}_1^{(+)}$ in the $\mathcal{C}$-enriched cases. In the case of (marked) pre-$\mathcal{C}^*$-categories, if we can identify $\tilde{Z}(a)$ with $Z(a)$ as a (marked) $\mathcal{C}$-linear $\ast$-category, then we can conclude that it is itself a (marked) pre-$\mathcal{C}^*$-category. Here we use that the inclusion of (marked) pre-$\mathcal{C}^*$-categories into (marked) $\mathcal{C}$-linear $\ast$-categories preserves colimits.

Furthermore we see by an inspection of the definition that $\tilde{Z}(a)$ is a (marked) $\mathcal{C}^*$-category if $A$ and $B$ were (marked) $\mathcal{C}^*$-categories.

We have a canonical morphism $B \to \tilde{Z}(a)$. Furthermore we have a morphism $A_{\sharp\mathbb{I}} \to \tilde{Z}(a)$ given by

1. $(x,0) \mapsto x$
2. $(x,1) \mapsto a(x)$

for $x$ an object of $A$, and which is fixed on morphisms by

1. $((f,\text{id}_0):(x,0) \to (y,0)) \mapsto f$
2. $(\text{id}_x,(0 \to 1)) \mapsto \text{id}_{a(x)}$
and the compatibility with composition and the \( \ast \)-operation. With these definitions the square in

\[
\begin{array}{ccc}
A & \xrightarrow{a} & B \\
\downarrow & & \downarrow \\
\bar{A} & \xrightarrow{\tilde{Z}(a)} & D
\end{array}
\]

commutes. Let now \( \phi \) and \( \psi \) be given as indicated. Then we define a morphism \( \tilde{Z}(a) \to D \) on objects by

\[
x \mapsto \begin{cases} 
\phi(x,0) & x \in A \\
\psi(y) & y \in B
\end{cases},
\]

and on morphisms by

\[
f \mapsto \begin{cases} 
\phi(f, \text{id}_0) & x, y \in A \\
\psi(f) & \text{else}
\end{cases}
\]

In fact this morphism is uniquely determined by the commutativity of the diagram. This implies that \( \tilde{Z}(a) \) is an explicit model for the push-out and hence a model for \( Z(a) \).

From now on we assume that \( Z(a) = \tilde{Z}(a) \). In this model the morphism \( q : Z(a) \to B \) is given by

1. \( q(x) = \begin{cases} 
a(x) & x \in A \\
x & x \in B
\end{cases} \)
2. \( q(f : x \to y) = \begin{cases} 
a(f) & x, y \in A \\
f & \text{else}
\end{cases} \)

It is surjective on objects. In order to see that \( q \) is a weak equivalence we define an inverse \( p : B \to Z(a) \) by

\[
p(x) := x, \quad p(f) := f.
\]

where both take values in the \( B \)-component. Then \( q \circ p = \text{id}_B \). Furthermore, a (marked) unitary isomorphism \( u : p \circ q \to \text{id}_{Z(a)} \) is given by \( u_x = \text{id}_x \) for \( x \) in \( B \) and \( \text{id}_{a(x)} \) for \( x \) in \( A \). It follows that \( q \) is good and a weak equivalence, hence a trivial fibration.

The morphism \( j : A \to Z(a) \) is the canonical embedding and clearly a cofibration. We therefore have constructed a functorial factorization

\[
(a : A \to B) \mapsto (A \xrightarrow{j} Z(a) \xrightarrow{q} B).
\]

We will use a functorial path object to obtain a functorial factorization

\[
\text{fibration } \circ \text{ trivial cofibration }
\]

We again use the notation Convention [6.14]
For a morphism $a : A \to B$ we define $P(a)$ as the pull-back

$$
P(a) \xrightarrow{\alpha} A \xrightarrow{a} B.$$

Using the universal property of the pull-back we get an extension of the diagram to

$$
\begin{array}{ccc}
A & \xrightarrow{j} & P(a) \\
\downarrow{\text{const}} & & \downarrow{\alpha} \\
\text{Fun}^\ast(I, B) & \xrightarrow{(1)^*} & B
\end{array}
$$

We finally extend the diagram as follows

$$
\begin{array}{ccc}
A & \xrightarrow{j} & P(a) \\
\downarrow{\text{const}} & & \downarrow{\alpha} \\
\text{Fun}^\ast(I, B) & \xrightarrow{(1)^*} & B
\end{array}
$$

by setting $p := a' \circ (0)^*$

The morphism $j$ is a cofibration since it is injective on objects because of $\alpha \circ j = \text{id}_A$.

We can describe $P(a)$ explicitly as the subcategory of $\text{Fun}^\ast(I, B) \times A$ determined on objects $(\phi, x)$ by the condition $\phi(1) = a(x)$ and on morphisms by $(u, f)$ by $u(1) = a(f)$. In this picture $j$ is given by

$$
j(x) := (\text{const}(a(x)), x), \quad j(f) = (\text{const}(a(f)), f).
$$

Note that $\alpha \circ j = \text{id}_A$ by construction. We furthermore find a (marked) unitary isomorphism $\text{id}_{P(a)} \to j \circ \alpha$ by

$$
u(\phi, x) := ((0 \mapsto \phi(0 \to 1), 1 \mapsto \text{id}_{a(x)}), \text{id}_x) : (\phi, x) \to (\text{const}(a(x)), x).
$$

This shows that $j$ is a weak equivalence. Hence $j$ is a trivial cofibration.
It remains to show that \( p \) is a fibration. By Corollary 9.9 it suffices to show that \( p \) is good. Let a (marked) unitary morphism \( u : p(\phi, x) \to b \) be given. Then we take
\[
c = ((0 \mapsto b, 1 \mapsto a(x); (0 \to 1) \mapsto u^{-1}), x)
\]
and define \( v : (\phi, x) \to c \) by \(((0 \mapsto u, 1 \mapsto \text{id}_{a(x)}, \text{id}_x))\). Then \( p(v) = u \). This shows that \( p \) is good. \( \square \)

### 10 The simplicial axioms

We assume that the category \( \mathcal{C} \) belongs to the list
\[
\{ \ast \text{Cat}_1, \ast \text{Cat}_1, C_{\text{pre}}^* \text{Cat}_1, C^* \text{Cat}_1, \ast C \text{Cat}_1^+, \ast \text{Cat}_1^+, C_{\text{pre}}^* \text{Cat}_1^+, C^* \text{Cat}_1^+ \}.
\]

In this section we verify that the model category structure on \( \mathcal{C} \) described in Definition 9.1 and with the simplicial structure introduced in Definition 6.19 is a simplicial model category [Hir03, Def. 9.1.6]. Note that the axiom M6 [Hir03, Def. 9.1.6] is satisfied, in view of the bijections (6.6), by the construction of the simplicial structure Definition 6.19. So it remains to verify the axiom M7 [Hir03, Def. 9.1.6]. This follows from Proposition [10.4] showing the dual version of M7 (as stated in [Hir03, Def. 9.1.6]), and the validity of M6.

We closely follow the argument given in [Del10] for \( C^* \)-categories.

**Lemma 10.1.** For \( A \) in \( \mathcal{C} \) the functor
\[
A^\dashv : \text{sSet} \to \mathcal{C}
\]
preserves (trivial) cofibrations.

**Proof.** Recall that this functor is defined in Definition 6.19 as the composition
\[
\text{sSet} \xrightarrow{\Pi} \text{Grpd}_1 \xrightarrow{A^\dashv} \mathcal{C}.
\]
In the following proof it is useful not to drop \( \Pi \) from the notation. If \( i : X \to Y \) is a cofibration of simplicial sets, then \( i \) is injective on zero simplices, and hence, by the explicit description of the functor \( \Pi \) given below the Definition 6.18 the morphism of groupoids \( \Pi(i) \) is injective on objects. This implies that \( A^\dashv \Pi(i) \) is injective on objects. Assume now that \( i \) is in addition weak equivalence. Then \( \Pi(i) \) is an equivalence of groupoids. Let \( j : \Pi(Y) \to \Pi(X) \) be an inverse equivalence and \( u : j \circ \Pi(i) \to \text{id}_{\Pi(X)} \) and \( v : \Pi(i) \circ j \to \text{id}_{\Pi(Y)} \) be the corresponding isomorphisms. Then we get a (marked) unitary isomorphism
\[
(A^\dashv u) : (A^\dashv j) \circ (A^\dashv \Pi(i)) \to \text{id}_{A^\Pi(X)}
\]
by \((A^\dashv u)_{(a,x)} := (\text{id}_a, u_x)\). Similarly, we have a (marked) unitary isomorphism
\[
(A^\dashv v) : (A^\dashv \Pi(i)) \circ (A^\dashv j) \to \text{id}_{A^\Pi(Y)}
\]
given by \((A^\dashv v)_{(a,x)} := (\text{id}_a, v_x)\). \( \square \)
Lemma 10.2. For a groupid $G$ the functor

$$-\sharp G : \mathcal{C} \to \mathcal{C}$$

preserves (trivial) cofibrations.

Proof. If $a : A \to B$ is a cofibration, then it is injective on objects. But then $a\sharp G$ is injective on objects and hence a cofibration. If $a$ is in addition a (marked) unitary equivalence, then $a\sharp G$ is a (marked) unitary equivalence, too. The argument is similar to the corresponding part of the argument in the proof of Lemma 10.1.

We consider a commutative square

$$
\begin{array}{ccc}
A & \xrightarrow{i} & B \\
\downarrow{f} & & \downarrow{g} \\
C & \xrightarrow{j} & D
\end{array}
$$

in $\mathcal{C}$.

Lemma 10.3. If $(10.1)$ is a pushout and $i$ is a trivial cofibration, then $j$ is a trivial cofibration.

Proof. Since $i$ is a trivial cofibration, there exists a morphism $i' : B \to A$ such that $i' \circ i = \text{id}_A$ and a (marked) unitary isomorphism $u : i \circ i' \to \text{id}_B$ satisfying $u \circ i = \text{id}_i$. By the universal property of the push-out, the morphism $f \circ i' : B \to C$ induces a morphism $j' : D \to C$ such that $j' \circ j = \text{id}_C$. In particular, $j$ is a cofibration.

The functor $-\sharp \mathbb{I} : \mathcal{C} \to \mathcal{C}$ is a left-adjoint by Proposition 6.16 and therefore preserves pushouts. Moreover, $g \circ u$ provides a (marked) unitary isomorphism $j \circ f \circ i' = g \circ i \circ i' \to g$.

Using Example 6.15 we consider the (marked) unitary isomorphism $g \circ u$ between functors from $B$ to $D$ as a morphism $B\sharp \mathbb{I} \to D$. Together with the morphism $C\sharp \mathbb{I} \to D$ corresponding $\text{id}_D$, by the universal property of the push-out diagram $(10.1)$ we obtain an induced morphism $D\sharp \mathbb{I} \to D$ which we can interpret as a (marked) unitary isomorphism $j \circ j' \to \text{id}_D$. This proves that $j$ is a weak equivalence.

We can now verify the simplicial axiom M7.

Proposition 10.4. Let $a : A \to B$ be a cofibration in $\mathcal{C}$ and $i : X \to Y$ be a cofibration in $\text{sSet}$. Then

$$(A \sharp Y) \sqcup_{A \sharp X} (B \sharp X) \to B \sharp Y$$

is a cofibration. Moreover, if $i$ or $a$ are in addition weak equivalences, then $(10.2)$ is a weak equivalence.
Proof. The set objects of the push-out one left-hand side of (10.2) is equal to the push-out
of the object sets. We write objects in \( A\sharp X \) as pairs \((\alpha, x)\).

Assume that the classes of \((\alpha, y)\) and \((\beta, x)\) in the push-out go to the same object which
is then \((\beta, y)\). Then \(a(\alpha) = \beta\) and \(i(x) = y\). This means that \((\alpha, y) = (\text{id}, i)(\alpha, x)\) and
\((\beta, x) = (a, \text{id})(\alpha, x)\). Consequently, the classes of \((\alpha, y)\) and \((\beta, x)\) in \((A\sharp Y) \cup_{A\sharp X} (B\sharp X)\)
coincide.

Assume now that the classes of \((\alpha, y)\) and \((\alpha', y')\) go to the same object which is necessarily
\((a(\alpha), y)\). Then \(\alpha = \alpha'\) and \(y = y'\).

Similarly, if the classes of \((\beta, x)\) and \((\beta', x')\) go to the same object which is necessarily
\((\beta, i(x))\), then \(\beta = \beta'\) and \(x = x'\).

This shows that the morphism marked by \(\square\) the extended diagram

\[
\begin{array}{ccc}
A\sharp X & \xrightarrow{c} & (A\sharp Y) \cup_{A\sharp X} (B\sharp X) \\
\downarrow{e} & & \downarrow{e} \\
B\sharp X & \xleftarrow{d} & B\sharp Y
\end{array}
\]

is injective on objects and hence a cofibration.

Assume that \(a\) is a weak equivalence. By Lemma 10.2 the map \(c\) is a trivial cofibration.

By Lemma 10.3 the morphism \(d\) is again a trivial cofibration. Since (again by Lemma
10.2) the morphism \(e\) is a trivial cofibration it follows from the two-out-of-three property
for weak equivalences verified in Lemma 9.11 that the morphism \(\square\) is a weak equivalence.

The case that \(i\) is a weak equivalence is similar using Lemma 10.1 for the horizontal
arrows.

\[ \square \]

11 Cofibrant generation and local presentability

Let \(C\) be a member of the list

\[ \{^*\text{Cat}_1, ^*C^*\text{Cat}_1, C^*\text{Cat}_1^+, ^*C^*\text{Cat}_1^+, C^*\text{Cat}_1^+\} \].

In this section we show that the model category structure on \(C\) described in Definition
9.1 is cofibrantly generated. We adapt the arguments given in [Del10, Sec. 4.1].

Recall from Section 4 that \(\Delta^0\) denotes the object classifier object in \(C\), and that the
groupoid \(\mathbb{I}\) denotes the isomorphism classifier object in \(\text{Cat}\). The morphism \(\Delta^0 \to \Delta^0\mathbb{I}\)
classifying the object 0 is a trivial cofibration since it is clearly injective on objects and a
(marked) unitary equivalence. So by Lemma 9.7 and Corollary 9.9 we can take

\[ J := \{\Delta^0 \to \Delta^0\mathbb{I}\} \]
as the set of generating trivial cofibrations.

We now define the set $I$ of generating cofibrations. We must distinguish various cases and the set $I$ will depend on the case:

| Case | $I$ |
|------|-----|
| $\ast \mathbf{Cat}_1$, $\ast \mathbf{c Cat}_1$ | $\{U, V, V^u, W, W^u\}$ |
| $\ast \mathbf{Cat}_1$ | $\{U, V, V^u, W, W^u\}$ |
| $\ast \mathbf{Cat}_1^+, \ast \mathbf{c Cat}_1^+$ | $\{U, V, V^+, W, W^+\}$ |
| $\ast \mathbf{Cat}_1^+$ | $\{U, V, V^+, W, W^+\}$ |

In the following we describe the details. We first assume that $\mathcal{C}$ belongs to the list $\{\ast \mathbf{Cat}_1, \ast \mathbf{c Cat}_1\}$. Then we consider the cofibrations $U, V, W$ defined as follows:

1. $U : \emptyset \to \Delta^0$.
2. We let $V : \Delta^0 \sqcup \Delta^0 \to \Delta^1$ classify the pair of objects $(0, 1)$ of the morphism classifier $\Delta^1$, see Definition 4.3.
3. We define $P$ by the push-out

$$
\begin{array}{ccc}
\Delta^0 \sqcup \Delta^0 & \xrightarrow{V} & \Delta^1 \\
\downarrow & & \downarrow \\
\Delta^1 & \xrightarrow{P} & P
\end{array}
$$

and let $W : P \to \Delta^1$ be the map induced by $\text{id}_{\Delta^1}$ and the universal property of the push-out.
4. We let $V^u : \Delta^0 \sqcup \Delta^0 \to \mathbf{1}$ classify the pair of objects $(0, 1)$ of the unitary morphism classifier $\mathbf{1}$, see Definition 4.10.
5. We define $P^u$ by the push-out

$$
\begin{array}{ccc}
\Delta^0 \sqcup \Delta^0 & \xrightarrow{V^u} & \mathbf{1} \\
\downarrow & & \downarrow \\
\mathbf{1} & \xrightarrow{P^u} & P^u
\end{array}
$$

and let $W^u : P^u \to \mathbf{1}$ be the map induced by $\text{id}_{\mathbf{1}}$ and the universal property of the push-out.

We set

$$I := J \cup \{U, V, V^u, W, W^u\} .$$

We now assume that that $\mathcal{C}$ belongs to the list $\{\ast \mathbf{Cat}_1^+, \ast \mathbf{c Cat}_1^+\}$. Then we consider the following cofibrations:
1. We let $V^+ : \Delta^0 \sqcup \Delta^0 \to 1^+$ classify the pair of objects $(0, 1)$ of the marked morphism classifier $1^+$, see Definition 4.12.

2. We define $P^+$ by the push-out

$$
\begin{array}{ccc}
\Delta^0 \sqcup \Delta^0 & \overset{V^+}{\longrightarrow} & 1^+ \\
\downarrow & & \downarrow \\
1^+ & \longrightarrow & P^+
\end{array}
$$

and let $W^+ : P^+ \to 1^+$ be the map induced by $\text{id}_{1^+}$ and the universal property of the push-out.

We then set

$$I := J \cup \{U, V, V^+, W, W^+\}.$$ 

We now consider the case that $\mathcal{C}$ belongs to the list $\{\mathbf{C}^*\text{Cat}_1\}$. In this case we must replace the morphism classifier by the bounded morphism classifier, see Lemma 4.3 and Definition 4.6. We consider the following cofibrations:

1. We let $V^{bd} : \Delta^0 \sqcup \Delta^0 \to \Delta^{1, bd}$ classify the pair of objects $(0, 1)$ of the bounded morphism classifier $\Delta^{1, bd}$, see Definition 4.6.

2. We define $P^{bd}$ as the push-out

$$
\begin{array}{ccc}
\Delta^0 \sqcup \Delta^0 & \overset{V^{bd}}{\longrightarrow} & \Delta^{1, bd} \\
\downarrow & & \downarrow \\
\Delta^{1, bd} & \longrightarrow & P^{bd}
\end{array}
$$

and let $W^{bd} : P^{bd} \to \Delta^{1, bd}$ be the map induced by $\text{id}_{\Delta^{1, bd}}$ and the universal property of the push-out.

We set

$$I := J \cup \{U, V, V^{bd}, W^{bd}, W^u\}.$$ 

Finally, in the case that $\mathcal{C}$ belongs to the list $\{\mathbf{C}^*\text{Cat}_1^+\}$, we set

$$I := J \cup \{U, V^{bd}, V^+, W^{bd}, W^+\}.$$ 

Let $\mathcal{C}$ be a member of the list

$$\{\mathbf{Cat}_1, \mathbf{Cat}_1^+, C^*\text{Cat}_1, \mathbf{Cat}_1^+, C^*\text{Cat}_1^+, \mathbf{Cat}_1^+, C^*\text{Cat}_1^+\}.$$ 

**Lemma 11.1.** The trivial fibrations in $\mathcal{C}$ are exactly the morphisms which have the right-lifting property with respect to $I$. 

49
Proof. In all cases, by Lemma 9.7 and Corollary 9.9 a morphism $f$ has the right-lifting property with respect to $J$ if and only if it is a fibration. So it remains to show that the right-lifting property of $f$ with respect to the remaining morphisms in $I$ is equivalent to the fact that $f$ is a weak equivalence.

We first consider the case where $C$ is in $\{\text{Cat}_1, \text{cCat}_1\}$. By Lemma 5.3.2 it suffices to show that the right-lifting property of $f$ with respect to $\{U, V, V^u, W, W^u\}$ is equivalent to the property that $F_{all}(f)$ (see (5.1) for notation) and $\text{ma}(f)^+$ (see (3.7) and Remark (2.20)) are equivalences of categories. This follows from the following observations:

1. The right-lifting property of $f$ with respect to $U$ is equivalent to surjectivity of $f$ on objects.
2. The right-lifting property of $f$ with respect to $V$ is equivalent to fullness of $F_{all}(f)$.
3. The right-lifting property of $f$ with respect to $W$ is equivalent to faithfulness of $F_{all}(f)$.
4. The right-lifting property of $f$ with respect to $V^u$ is equivalent to fullness of $\text{ma}(f)^+$.
5. The right-lifting property of $f$ with respect to $W^u$ is equivalent to faithfulness of $\text{ma}(f)^+$.

Indeed, these conditions imply that $F_{all}(f)$ and $\text{ma}(f)^+$ are equivalence of categories. For the converse, if $f$ is a fibration and $F_{all}(f)$ is an equivalence of categories, then $f$ is necessarily surjective on objects.

We next discuss the case where $C$ is in $C\text{Cat}_1$. By Lemma 5.3.2 it suffices to show that the right-lifting property of $f$ with respect to $\{U, V^{bd}, V^u, W^{bd}, W^u\}$ is equivalent to the property that $F_{all}(f)$ and $\text{ma}(f)^+$ are equivalences of categories. This follows from the following observations:

1. The right-lifting property of $f$ with respect to $U$ is equivalent to surjectivity of $f$ on objects.
2. The right-lifting property of $f$ with respect to $V^{bd}$ is equivalent to the surjectivity of $f$ on the subspaces of the morphisms of maximal norm bounded by 1. Since a linear map between pre-normed vector spaces is surjective if it is so on vectors of norm bounded by 1 this implies that $f$ is full.
3. The right-lifting property of $f$ with respect to $W^{bd}$ is equivalent to the injectivity of the restriction of $f$ to the subspace of morphisms of norm bounded by 1. This implies that $f$ is faithful.
4. The right-lifting property of $f$ with respect to $\{V^u, W^u\}$ is equivalent to fully faithfulness of $\text{ma}(f)^+$.

We now consider the case that $C$ is in $\{\text{Cat}^+_1, \text{cCat}^+_1\}$. In view of Lemma 5.3.1 we must show that the right-lifting property of $f$ with respect to $\{U, V, V^+, W, W^+\}$ is equivalent to the fact that $F_{all}(f)$ and $f^+$ are equivalences of categories. We conclude by the following observations.
1. The right-lifting property of \( f \) with respect to \( \{U,V,W\} \) is equivalent to the fact that \( \mathcal{F}_{\text{all}}(f) \) is an equivalence of categories which is surjective on objects.

2. The right-lifting property of \( f \) with respect to \( V^+ \) is equivalent to fullness of \( f^+ \).

3. The right-lifting property of \( f \) with respect to \( W^+ \) is equivalent to faithfulness of \( f^+ \).

We finally consider the case that \( C \) is in \( \{C^*\text{Cat}_1^+, \ast\text{Cat}_1, C\ast\text{Cat}_1, C^*\text{Cat}_1^+, \ast\text{Cat}_1^+, \ast\ast\text{Cat}_1, \ast\ast\text{Cat}_1^+\} \). Again by Lemma \ref{5.3.1} we must show that the right-lifting property of \( f \) with respect to \( \{U,V^bd, V^bd, V^+, W^bd, W^+\} \) is equivalent to the fact that \( \mathcal{F}_{\text{all}}(f) \) and \( f^+ \) are equivalences of categories. This follows from the following two observations already made above:

1. The right-lifting property of \( f \) with respect to \( \{U, V^bd, W^bd\} \) is equivalent to the fact that \( \mathcal{F}_{\text{all}}(f) \) is an equivalence of categories which is surjective on objects.

2. The right-lifting property of \( f \) with respect to \( \{U, V^+, W^+\} \) is equivalent to the fact that \( f^+ \) is an equivalence of categories which is surjective on objects.

Let \( \kappa \) be a regular cardinal. A partially ordered set \( I \) is called \( \kappa \)-filtered if every subset of cardinality \( < \kappa \) has an upper bound. A \( \kappa \)-filtered diagram is a diagram indexed by a \( \kappa \)-filtered partially ordered set. An object \( A \) in a category \( C \) is called \( \kappa \)-compact if the functor

\[
\text{Hom}_C(A, -) : C \to \text{Set}
\]

preserves \( \kappa \)-directed colimits. The object is called small if it is \( \kappa \)-compact for some regular cardinal \( \kappa \).

Let \( C \) be a member of the list

\[
\{\ast\text{Cat}_1, \ast\ast\text{Cat}_1, C^*\text{Cat}_1, \ast\text{Cat}_1^+, \ast\ast\text{Cat}_1^+, C^*\text{Cat}_1^+\}. 
\]

In the following lemma the classifier objects (and the objects \( P, P^+ \) derived from them) are associated to \( C \).

**Lemma 11.2.** 1. The objects \( \emptyset, \Delta^0, 1, P^u \) and \( 1^+, P^+ \) (in the marked cases) are compact (i.e., \( \aleph_0 \)-compact).

2. The objects \( \Delta^1 \) and \( P \) (if defined) are \( \aleph_1 \)-compact.

3. The objects \( \Delta^{1, \text{bd}} \) and \( P^{\text{bd}} \) (if defined) are \( \kappa \)-compact, where \( \kappa \) is a regular cardinal greater than the maximum of the dimensions of the morphism spaces \( \text{Hom}_{\Delta^{1, \text{bd}}}(j,k) \) for \( j, k \) in \( \{0, 1\} \).

---

\(^8\)We follow the terminology of [Lur09]. In [AR94, Def. 1.13] the word \( \kappa \)-directed is used.

\(^9\)We again follow the terminology of [Lur09]. In [AR94] the term \( \kappa \)-presented is used. A \( \aleph_0 \)-compact object is also called finitely presented, or just compact.
Proof. The assertions easily follow by an inspection of the descriptions of the explicit models for these classifier categories given in Section 4. The main observation for 1. is that the respective categories have finitely many objects and finite-dimensional morphism spaces. Similarly for 2. we use that \( \Delta^1 \) and \( P \) have two objects and that their morphism spaces are countable or have countable dimension in the \( C \)-linear cases. Finally for 3. we use that the categories have the two objects 0, 1.

**Corollary 11.3.** The model category \( \mathcal{C} \) is cofibrantly generated by finite sets of generating cofibrations and trivial cofibrations between small objects.

We now show that six of our eight examples are combinatorial. We first discuss the case of (marked) \( \ast \)-categories and (marked) \( \mathbb{C} \)-linear \( \ast \)-categories. The argument in the case of \( \mathbb{C} \)-\( \ast \)-categories is different and will be given in a separate Proposition 11.7 below. In view of Corollary 11.3 it suffices to verify local presentability.

The following serves as a preparation of the proof of Proposition 11.5.

Let \( \mathcal{C} \) be some category. Recall from [AR94, Sec. 0.6] that a generator of \( \mathcal{C} \) is a set of objects \( G \) of \( \mathcal{C} \) such that for every two distinct morphisms \( f, g : C \to D \) in \( \mathcal{C} \) there exists a morphism \( h : G \to C \) for some \( G \) in \( G \) such that \( f \circ h \neq g \circ h \). The generator is strong if in addition for every object \( C \) of \( \mathcal{C} \) and proper subobject \( D \) of \( \mathcal{C} \) there exists a morphism \( h : G \to C \) for some \( G \) in \( \mathcal{G} \) which does not factor over \( D \).

Let \( \mathcal{G} \) be a subset of objects of \( \mathcal{C} \).

**Lemma 11.4.** If every object of \( \mathcal{C} \) is isomorphic to a colimit of a diagram in \( \mathcal{C} \) with values in \( \mathcal{G} \), then \( \mathcal{G} \) is a strong generator of \( \mathcal{C} \).

**Proof.** Let \( f, g : C \to D \) be two distinct morphisms in \( \mathcal{C} \). Let \( B : I \to \mathcal{C} \) be a diagram with values in \( \mathcal{G} \) such that \( C \cong \text{colim}_I B \). Then we have a bijection of sets

\[
\lim_{\longrightarrow} \text{Hom}_\mathcal{C}(B, D) \cong \text{Hom}_\mathcal{C}(C, D).
\]

Because of \( f \neq g \) there exists \( i \) in \( I \) such that \( f \circ h(i) \neq g \circ h(i) \), where \( h(i) : B(i) \to \text{colim}_I B \cong C \) is the canonical map. Note that \( B(i) \) belongs to \( \mathcal{G} \) by assumption.

Let now \( \iota : D \to C \) be the inclusion of a proper subobject. We again consider a diagram \( B : I \to \mathcal{C} \) with values in \( \mathcal{G} \) such that \( C \cong \text{colim}_I B \).

We argue by contradiction and assume that every morphism \( G \to C \) with \( G \) in \( \mathcal{G} \) factors over \( \iota \). Since \( D \) is a subobject this factorization is unique. The canonical morphism of \( I \)-diagrams \( B \to C \) therefore provides a morphism of \( I \)-diagrams \( B \to D \) and hence a morphism \( \pi : C \cong \text{colim}_I B \to D \) by the universal property of the colimit. Since \( B \to D \xrightarrow{\pi} C \) is the canonical morphism of \( I \)-diagrams for the presentation of \( C \) we conclude that \( \iota \circ \pi = \text{id}_C \). We now argue that also \( \pi \circ \iota = \text{id}_\mathcal{G} \) and hence \( \iota \) is an isomorphism. This is in conflict with the assumption that \( \iota \) is the inclusion of a proper subobject, and hence we get the desired contradiction. We know that

\[
\iota \circ (\pi \circ \iota) = (\iota \circ \pi) \circ \iota = \text{id}_C \circ \iota = \iota.
\]
Since also $\iota \circ \text{id}_D = \iota$ and $\iota$ is a monomorphism, we conclude that $\text{id}_D = \pi \circ \iota$ as required. \hfill \Box

If $\mathcal{G}$ satisfies the assumption of Lemma 11.4, then we say that $\mathcal{G}$ strongly generates $\mathcal{C}$.

**Proposition 11.5.** If $\mathcal{C}$ belongs to $\{\ast \text{Cat}_1, \ast_c \text{Cat}_1, \ast \text{Cat}_1^+, \ast_c \text{Cat}_1^+\}$, then the category $\mathcal{C}$ is locally presentable.

**Proof.** The categories in question are cocomplete. By [AR94, Thm. 1.20] it suffices to show that they have a strong generator formed by $\kappa$-presentable objects for some regular cardinal $\kappa$. In order to exhibit a strong generator will use the criterion shown in Lemma 11.4.

We start with the case $\ast \text{Cat}_1$. The following discussion is related with Remark 8.3. A directed $\ast$-graph is a directed graph with an involution which preserves vertices and flips the direction of edges. We consider the category $\ast \text{DirGraph}$ of directed $\ast$-graphs and involution-preserving morphisms. Then we have an adjunction

$$
\text{Free}_{\ast \text{Cat}} : \ast \text{DirGraph} \rightleftarrows \ast \text{Cat}_1 : F,
$$

(11.1)

where $F_\circ$ forgets the category structure and retains the $\ast$-operation. The left-adjoint $\text{Free}_{\ast \text{Cat}}$ sends a directed $\ast$-graph to the $\ast$-category freely generated by it. The category $\ast \text{DirGraph}$ is locally presentable. Indeed, it is cocomplete (as in the case of directed graphs, colimits are given by the colimits of the sets of vertices and edges, separately), and it is strongly generated by the objects in the list

$$
\{\text{pt}, F_\circ(1)\}
$$

of compact directed $\ast$-graphs. Note that $\text{pt}$ is the directed $\ast$-graph with one vertex and no edges, and the directed $\ast$-graph $F_\circ(1)$ has two vertices 0 and 1 and the edges $u : 0 \rightarrow 1$ and $u^* : 1 \rightarrow 0$. Given a $\ast$-category $\mathbf{A}$ we can consider the free $\ast$-category

$$
F(\mathbf{A}) := \text{Free}_{\ast \text{Cat}}(F_\circ(\mathbf{A}))
$$

generated by the underlying directed $\ast$-graph of $\mathbf{A}$. The counit of the adjunction (11.1) provides a canonical morphism

$$
v_\mathbf{A} : F(\mathbf{A}) \rightarrow \mathbf{A}
$$

doing $\ast$-categories. We claim that $v_\mathbf{A}$ is an effective epimorphism, i.e, canonical coequalizer map

$$
cv_\mathbf{A} : \text{Coeq}(F(\mathbf{A}) \times_\mathbf{A} F(\mathbf{A}) \Rightarrow F(\mathbf{A})) \rightarrow \mathbf{A}
$$

is an isomorphism in $\ast \text{Cat}_1$. We first observe that $v_\mathbf{A}$ induces a bijection on the level of objects. Consequently, the coequalizer map $cv_\mathbf{A}$ is a bijection on the level of objects, too. The morphisms of the coequalizer are given as a quotient of the morphisms in $F(\mathbf{A})$ by the equivalence relation induced by $v_\mathbf{A}$ which is compatible with the $\ast$-category structure. It is now clear that $cv_\mathbf{A}$ is also a bijection on morphisms.
We know that $F(A)$ is isomorphic to a colimit of a diagram involving the generators

$$\{pt, F(1)\}.$$  \hfill (11.2)

Note that the fibre product over $A$ is not a colimit. But we have a surjection

$$F(F(A) \times_A F(A)) \to F(A) \times_A F(A)$$

and therefore an isomorphism

$$\text{Coeq} \left( F(F(A) \times_A F(A)) \rightrightarrows F(A) \right) \to A .$$

The $*$-category $F(F(A) \times_A F(A))$ is again a colimit of a diagram involving the generators in the list above. Hence $A$ itself is a colimit of a diagram built from the list \(\text{(11.2)}\). Since $F(\mathbb{I})$ has two objects and countable morphism sets it is $\aleph_1$-presentable. It follows that $^*\text{Cat}_i$ is strongly generated by the list \(\text{(11.2)}\) of $\aleph_1$-presentable objects.

In the case of $^*\text{Cat}_1^+$ we argue similarly. We use the adjunction

$$\text{Free}_{\text{cat}^+} : ^*\text{DirGraph}^+ \rightleftarrows ^*\text{Cat}_1^+ : \mathcal{F}_o$$  \hfill (11.3)

and that the category of marked directed $*$-graphs $^*\text{DirGraph}^+$ is strongly generated by the list compact objects

$$\{pt, \mathcal{F}_o(\text{mi}(1_{^*\text{Cat}_1})), \mathcal{F}_o(\text{ma}(1_{^*\text{Cat}_1}))\} .$$

We can now repeat the argument. It follows that $^*\text{Cat}_i^+$ is strongly generated by the list of $\aleph_1$-presentable objects

$$\{pt, F(\text{ma}(1_{^*\text{Cat}_1})), F(\text{mi}(1_{^*\text{Cat}_1}))\} .$$

A similar argument applies in the $\mathbb{C}$-linear case. Here we use the adjunction \((3.2)\) and the counit

$$v_A : F_C(A) := \text{Lin}_\mathbb{C}(F_C(A)) \to A .$$

We again show that $v_A$ is an effective coequalizer and get an isomorphism

$$\text{Coeq} \left( F_C(F_C(A) \times_A F_C(A)) \rightrightarrows F_C(A) \right) \to A .$$

From the already verified case $^*\text{Cat}_1$ and the fact that the left-adjoint $\text{Lin}_\mathbb{C}$ preserves colimits we conclude that for every $B$ in $^*\text{Cat}_1$ the object $F_C(B)$ is a colimit of a diagram with values in the list

$$\{\text{Lin}_\mathbb{C}(pt), \text{Lin}_\mathbb{C}(F(1_{^*\text{Cat}_1}))\} .$$  \hfill (11.4)

Since $\text{Lin}_\mathbb{C}(F(1_{^*\text{Cat}_1}))$ has two objects and countable-dimensional morphism spaces it is $\aleph_1$-presentable. It follows that $^*_C\text{Cat}_1$ is strongly generated by the list \(\text{(11.4)}\) of $\aleph_1$-presentable objects.

Similarly, $^*_C\text{Cat}_i^+$ is strongly generated by the list of $\aleph_1$-presentable objects

$$\{\text{Lin}_\mathbb{C}(*) , \text{Lin}_\mathbb{C}(F(\text{mi}(1_{^*\text{Cat}_1}))), \text{Lin}_\mathbb{C}(F(\text{ma}(1_{^*\text{Cat}_1})))\} .$$

$\Box$
Remark 11.6. At the moment we do not have an argument that $C^*_\pre{\mathbf{Cat}_1}^+$ or $C^*_\pre{\mathbf{Cat}_1}$ are locally presentable.

Let $\mathbf{A}$ be a pre-$C^*$-category. Then by the above there exists a functor $S : I \to \mathbf{C}_c\mathbf{Cat}_1$ such that $S(i)$ belongs to the list (11.3) for all $i$ in $I$ together with a transformation $u : S \to \mathbf{const}(\mathbf{F}_{\pre{\mathbf{A}}})$ such that its adjoint is an isomorphism $\text{colim}_I S \cong \mathbf{F}_{\pre{\mathbf{A}}}$. Then

$$\text{colim}_I \text{Bd}^\infty(S) \to \mathbf{A}$$

is a candidate for a presentation of $\mathbf{A}$.

Proposition 11.7. The categories $C^*_\mathbf{Cat}_1$ and $C^*_\mathbf{Cat}_1^+$ are locally presentable.

Proof. There is a set $\mathfrak{DirGraph}_{\text{fin}}$ of finite directed $*$-graphs. For any directed $*$-graph $Q$ we can consider the $\mathbb{C}$-linear $*$-category $\text{Lin}_\mathbb{C}(\mathbf{Free}_{\mathbf{Cat}_1}(Q))$ (see (11.1) for notation). We have a set of $C^*$-norms $N(Q)$ on $\text{Lin}_\mathbb{C}(\mathbf{Free}_{\mathbf{Cat}_1}(Q))$. For every norm $\| - \|$ in $N(Q)$ we form the $C^*$-category $\mathbf{A}(Q, \| - \|)$ by taking the closure.

We claim that the set of $C^*$-categories $\mathbf{A}(Q, \| - \|)$ as described above for all finite directed $*$-graphs $Q$ and norms $\| - \|$ in $N(Q)$ strongly generates $C^*_\mathbf{Cat}_1$.

Let $\mathbf{A}$ be a $C^*$-category. Any finite $*$-invariant collection $F$ of morphisms of $\mathbf{A}$ defines a finite directed $*$-graph $Q(F)$ by forgetting the composition. By the universal property of the $\text{Lin}_\mathbb{C} \circ \mathbf{Free}_{\mathbf{Cat}_1}$-functor we have a canonical morphism

$$\text{Lin}_\mathbb{C}(\mathbf{Free}_{\mathbf{Cat}_1}(Q(F))) \to \mathbf{A}$$

which induces a norm $\| - \|_F$ in $N(Q(F))$. Then $A(F) := \mathbf{A}(Q(F), \| - \|_F)$ is naturally isomorphic to a sub $C^*$-category of $\mathbf{A}$. The set of finite $*$-invariant subsets of morphisms of $\mathbf{A}$ is partially ordered by inclusion and filtered. If $F$ is contained in a larger subset $F'$, then we clearly get a monomorphism $A(F) \to A(F')$ of $C^*$-categories. We claim that

$$\text{colim}_F A(F) \cong A.$$

To this end we verify the universal property of the colimit. Let $\mathbf{B}$ be a $C^*$-category. We must produce a natural bijection

$$\text{Hom}_{C^*_\mathbf{Cat}_1}(\mathbf{A}, \mathbf{B}) \cong \text{lim}_F \text{Hom}_{C^*_\mathbf{Cat}_1}(A(F), \mathbf{B}).$$

This bijection identifies a morphism $\Phi$ in $\text{Hom}_{C^*_\mathbf{Cat}_1}(\mathbf{A}, \mathbf{B})$ with the morphism $\Psi$ in $\text{lim}_F \text{Hom}_{C^*_\mathbf{Cat}_1}(A(F), \mathbf{B})$. Given $\Phi$ we can find the system $\Psi = (\Psi_F)_F$ by $\Psi_F := \Phi|_{A(F)}$. Vice versa, given $\Psi = (\Psi_F)_F$, then we define $\Phi$ as follows. Let $a$ be an object of $\mathbf{A}$. Then we define $\Phi(a) := \Psi_{\{a\}}(a)$. For a morphism $(f : a \to a')$ in $\mathbf{A}$ we consider any $F$ such that $f \in F$. Then we define $\Phi(f) := \Psi_F(f)$. Note that $\Psi_F(f)$ is really a morphism from $\Phi(a)$ to $\Phi(a')$. Furthermore, one checks that this definition is independent of the choice of $F$. Therefore we get maps $\Phi$ on the level of objects and morphisms. We now show that $\Phi$ is a morphism between $\mathbb{C}$-linear $*$-categories. We discuss the compatibility
with composition. Let \( f \) and \( g \) be composable morphisms. Then we choose \( F \) such that \( f, g, g \circ f \in F \) and use that \( \Psi_F \) is a morphism of \( C^* \)-categories.

We now claim that the \( C^* \)-categories \( A(Q, \| - \|) \) for finite directed *-graphs and norms \( \| - \| \) in \( N(Q) \) are \( \aleph_2 \)-compact. Let

\[
B : I \to C^* \text{Cat}_1, \quad i \mapsto B(i)
\]

be an \( \aleph_2 \)-filtered diagram of \( C^* \)-categories and consider the natural map

\[
V : \lim_{i \in I} \text{Hom}_{C^* \text{Cat}_1}(A(Q, \| - \|), B(i)) \to \text{Hom}_{C^* \text{Cat}_1}(A(Q, \| - \|), \lim_{i \in I} B(i)). \quad (11.5)
\]

We must show that \( V \) is a bijection. We first discuss the surjectivity of \( V \). Let \( \Psi \) belong to \( \text{Hom}_{C^* \text{Cat}_1}(A(Q, \| - \|), \lim_{i \in I} B(i)) \).

Since the directed *-graph \( Q \) is finite there exists an element \( i \) in \( I \) such that \( \Psi(Q) \subseteq B(i) \).

For every \( j \) in \( I \geq i \) we get a morphisms of \( C \)-linear *-categories \( \rho_j : \text{Lin}_{C}(\text{Free-} \text{Cat}(Q)) \to B(i) \to B(j) \).

This morphism induces a norm \( \| - \|_j \) on \( \text{Lin}_{C}(\text{Free-} \text{Cat}(Q)) \) by \( \| a \|_j := \| \rho_j(a) \|_{B(j)}. \) If we can show that \( \| - \|_k \leq \| - \| \) for some \( k \) in \( I \geq i \), then we get the desired factorization \( \Phi : A(Q, \| - \|) \to B(k) \) such that \( V(\Phi) = \Psi \).

In order to find the element \( k \) we consider the set \( N(Q) \) of norms on \( \text{Lin}_{C}(\text{Free-} \text{Cat}(Q)) \) as a partially ordered set. Then we have an order-preserving map

\[
\ell : I \geq i \to N(Q)^{\text{op}}, \quad j \mapsto \| - \|_j.
\]

We now observe that the size of \( N(Q) \) is bounded by \( \aleph_1 \). A norm on \( \text{Lin}_{C}(\text{Free-} \text{Cat}(Q)) \) is determined by its restriction to the subcategory \( \text{Lin}_Q(\text{Free-} \text{Cat}(Q)) \). We then use that \( \text{Lin}_Q(\text{Free-} \text{Cat}(Q)) \) has countably many morphisms.

We let \( J \) be a subset of objects of \( I \geq i \) obtained by choosing a preimage under \( \ell \) for every norm in the image \( \ell(I \geq i) \). Then the size of \( J \) is bounded by \( \aleph_1 \). Since \( J \) is \( \aleph_2 \)-filtered the subset \( J \) has an upper bound \( k \) in \( I \geq i \). Then by construction \( \| - \|_k \leq \| - \|_j \) for all \( j \) in \( I \geq i \).

Since for every morphism \( a \) in \( \text{Lin}_{C}(\text{Free-} \text{Cat}(Q)) \) we have the inequality

\[
\| a \|_k \leq \lim_{j \in I \geq i} \| \rho_j(a) \|_{B(j)} = \| \Psi(a) \|_{\lim_{i \in I} B(j)} \leq \| a \|
\]

we have \( \| - \|_k \leq \| - \| \) as desired.

We now consider injectivity of \( V \) in (11.5). Assume that \( \Phi, \Phi' \) in

\[
\lim_{i \in I} \text{Hom}_{C^* \text{Cat}_1}(A(Q, \| - \|), B(i))
\]

are distinct. Then there exists a morphism \( a \) in \( \text{Lin}_{C}(\text{Free-} \text{Cat}(Q)) \) such that \( \Phi(a) \neq \Phi'(a) \).
are such that $V(\Phi) = V(\Phi')$. We can assume that there is an element $j$ in $I$ such that $\Phi$ and $\Phi'$ are represented by morphisms $\Phi_j, \Phi'_j$ in $\text{Hom}_{\text{Cat}}(A(Q, \| - \|), B(j))$. For every $i$ in $I_{\geq j}$ we write $\Phi_i$ and $\Phi'_i$ for the morphisms obtained from $\Phi_j$ and $\Phi_j$ by post-composition with $B(j) \rightarrow B(i)$. We must then show that there exists $k$ in $I_{\geq j}$ such that $\Phi_k = \Phi'_k$.

Using that $Q$ is finite, after increasing $j$ if necessary, we can assume that $\Phi_j$ and $\Phi'_j$ coincide on objects. We furthermore write $V_i$ for the composition of $V$ with the canonical map

$$\text{Hom}_{\text{Cat}}(A(Q, \| - \|), B(i)) \rightarrow \lim_{i \in I_{\geq j}} \text{Hom}_{\text{Cat}}(A(Q, \| - \|), B(l)).$$

For a morphism $\phi$ in $A(Q, \| - \|)$ we have the equality

$$0 = \| V(\Phi(\phi)) - V(\Phi'(\phi))\| = \lim_{i \in I_{\geq j}} \| \Phi_i(\phi) - \Phi'_i(\phi)\| \quad (11.6)$$

(note that the difference makes sense since $\Phi_i$ and $\Phi'_i$ coincide on objects).

We now use that, by continuity, $\Phi_i$ and $\Phi_i'$ are uniquely determined by their restrictions along the functor

$$d : \text{Lin}_Q(\text{Free}_{\text{Cat}}(Q)) \rightarrow A(Q, \| - \|).$$

Because of $(11.6)$, for every morphism $\phi$ in $\text{Lin}_Q(\text{Free}_{\text{Cat}}(Q))$ and positive real number $r$ we can choose $i(\phi, r)$ in $I_{\geq j}$ such that

$$\| \Phi_{i(\phi, r)}(d(\phi)) - \Phi'_{i(\phi, r)}(d(\phi))\| \leq r.$$

Since the size of the set of morphisms $\phi$ and positive real numbers $r$ is bounded by $\aleph_1$ and $I$ is $\aleph_2$-filtered there exists an element $k$ in $I_{\geq j}$ which is greater than all the elements $i(\phi, r)$ chosen above. We conclude that $\| \Phi_k(d(\phi)) - \Phi'_k(d(\phi))\| = 0$ for all morphisms $\phi$ in $\text{Lin}_Q(\text{Free}_{\text{Cat}}(Q))$ and consequently $\Phi_k = \Phi'_k$. This finally implies that $\Phi = \Phi'$.

This finishes the proof of the Proposition 11.7 in the case of $C^*\text{Cat}_1$. In the case of $C^*\text{Cat}^+_1$ we argue similarly with marked directed $*$-graphs and use the functor $\text{Free}_{\text{Cat}^+}$ from $(11.3)$ instead of $\text{Free}_{\text{Cat}}$.

**Corollary 11.8.** The model category structures on the categories $C$ in the list

$$\{^*\text{Cat}_1, ^*c\text{Cat}_1, C^*\text{Cat}_1, ^*\text{Cat}_1^+, ^*c\text{Cat}_1^+, C^*\text{Cat}_1^+\}$$

are combinatorial.

**12 The construction** $A \mapsto \hat{A}^G$

Let $G$ be a group. The category of $G$-objects in a category $C$ is defined as the functor category $\text{Fun}(BG, C)$, where $BG$ is as in Example 2.2.

We now assume that the category $C$ belongs to the list

$$\{^*\text{Cat}_1, ^*c\text{Cat}_1, C^*\text{pre Cat}_1, C^*\text{Cat}_1, ^*\text{Cat}_1^+, ^*c\text{Cat}_1^+, C^*\text{pre Cat}_1^+, C^*\text{Cat}_1^+\}.$$
As explained in Section 1.2 one of the purposes of the present paper is to calculate the object $\lim_{BG} \ell_{BG}(A)$ in $\mathcal{C}_\infty$ for $A$ in $\text{Fun}(BG, \mathcal{C})$, and that calculation of the limit amounts more precisely to provide an object $B$ of $\mathcal{C}$ and equivalence $\ell(B) \simeq \lim_{BG} \ell_{BG}(A)$. In this section we define the candidate for $B$ which will be denoted by $\hat{A}^G$. We refer to Theorem 13.6 for the justification and the actual calculation of the limit. The main point of the present section is the explicit description of $\hat{A}^G$ provided in Remark 12.2.

We consider a $G$-object $A$ in $\mathcal{C}$ and let $\text{Fun}^\ast(\hat{G}, A)$ be as in Section 7.

**Definition 12.1.** We define the object $\hat{A}^G$ in $\mathcal{C}$ by

$$\hat{A}^G := \lim_{BG} \text{Fun}^\ast(\hat{G}, A).$$

**Remark 12.2.** In this remark we derive an an explicit description of $\hat{A}^G$. Note that the limit in (12.1) is interpreted in $\mathcal{C}$, and that the details of this interpretation depend on the case.

We first assume that $\mathcal{C}$ belongs to the list

$$\{ \ast \text{Cat}_1, \ast \_\text{Cat}_1, \ast \text{Cat}_1^+, \ast \_\text{Cat}_1^+ \}.$$  

(12.2)

In all these cases the underlying category of $\hat{A}^G$ is the category of $G$-invariant functors in $\text{Fun}^\ast(\hat{G}, A)$. Hence an object $a$ of $\hat{A}^G$ associates to every object $g$ of the $G$-groupoid $\hat{G}$ an object $a(g)$ in $A$. Furthermore, for every pair of objects $g, h$ in $\hat{G}$ we have a (marked) unitary morphism $a(g \rightarrow h) : a(g) \rightarrow a(h)$ in $A$. The condition that the functor $a$ is $G$-invariant means that for every group element $k$ in $G$ we have the equalities $a(kg) = k(a(g))$ and $a(kg \rightarrow kh) = k(a(g \rightarrow h))$. Therefore, the object $a$ of $\hat{A}^G$ is completely determined by the object $a(1)$ of $A$ and a collection of (marked) unitary morphisms $\rho(g) = a(1 \rightarrow g) : a(1) \rightarrow g(a(1))$ which satisfy the cycle condition

$$g(\rho(h)) \circ \rho(g) = \rho(hg)$$

for all elements $g, h$ of $G$. We will therefore write objects of $\hat{A}^G$ as pairs $(b, \rho)$ with $b$ in $A$ and $\rho = (\rho(g))_{g \in G}$ a cocycle as above with $\rho(g) : b \rightarrow g(b)$ for all $g$ in $G$.

Again by $G$-invariance, a morphism $a \rightarrow a'$ between objects of $\hat{A}^G$ is determined by its restriction to $a(1)$ which necessarily intertwines the cocycles, i.e., which satisfies

$$\rho'(g) \circ f(1) = g(f(1)) \circ \rho(g)$$

for all elements $g$ of $G$. In other words, a morphism $f : (b, \rho) \rightarrow (b', \rho')$ is a morphism $f : b \rightarrow b'$ in $A$ such that $\rho'(g) \circ f = f \circ \rho(g)$ for all $g$ in $G$. We call such a morphism an intertwiner.

Consequently, the category $\hat{A}^G$ is isomorphic to the category of pairs $(b, (\rho(g))_{g \in G})$ of an object $b$ of $A$ and a cocycle $\rho$, and intertwiners.

The $\ast$-operation on the category $\hat{A}^G$ is induced by the $\ast$-operation on $A$. If $A$ was a $\mathbb{C}$-linear $\ast$-category, then so is $\hat{A}^G$. In the marked case, marked morphisms in $\hat{A}^G$ are
inter-twinnners which are marked morphisms in $A$. This finishes the description of $\hat{A}^G$ in the case that $C$ belongs to the list (12.2).

In order to calculate $\hat{A}^G$ in the cases where $C$ belongs to the list $$\{C_{pre}^*, C_{pre}^+\}$$ we use the adjunction $(F_{pre}, Bd^\infty)$ given in Lemma 3.8.3. We have an isomorphism

$$\lim_{BG} \cong Bd^\infty \circ \lim_{BG} F_{pre}$$

(12.3)

de an isomorphism of functors from $\text{Fun}(BG, C)$ to $C$, where the limit on the right-hand side is interpreted (marked) $\mathbb{C}$-linear $*$-categories. Consequently we get an isomorphism

$$\hat{A}^G \cong Bd^\infty(\hat{F}_{pre}(A)^G_+).$$

(12.4)

In other words, if $A$ is a (marked) pre-$C^*$-category, then we can calculate $\hat{A}^G$ by applying the $(-)^G$-construction to $A$ considered as a (marked) $\mathbb{C}$-linear $*$-category, and then applying the functor $Bd^\infty$.

Finally we assume that $C$ belongs to the list $$\{C^*\text{Cat}_1^+, C^*\text{Cat}_1^+\}.$$ In this case we use that the forgetful functor (see (3.4)) $F_- : C^*\text{Cat}^+(+)^\to C^*\text{preCat}^+(+)$ preserves limits and reflects isomorphisms. We thus have

$$\hat{A}^G \cong F_-(A)^G \cong Bd^\infty(\hat{F}_{pre}(F_-(A))_+^G) \cong \hat{F}_{pre}(F_-(A))_+^G.$$

In order to justify the isomorphism marked by $!$ note that the (marked) $\mathbb{C}$-linear $*$-category $\hat{F}_{pre}(F_-(A))_+^G$ is again a $C^*$-category since the space of morphisms from the object $(b, (\rho(g))_{g \in G})$ to the object $(b', (\rho'(g))_{g \in G})$ is a closed subset of $\text{Hom}_A(b, b')$, and the $C^*$-property is induced. Here we use the description of $C^*$-categories given in Remark 2.15.

In other words, if $A$ is a (marked) $C^*$-category, then we can calculate $\hat{A}^G$ by applying the $(-)^G$-construction to $A$ considered as a marked $\mathbb{C}$-linear $*$-category, and then noting that the result is in fact a $C^*$-category.

$\square$
13 Infinity-categorical $G$-fixed points

Let $\mathcal{C}$ be a model category and $I$ be a small category. For every $i$ in $I$ we have an evaluation functor $e_i : \text{Fun}(I, \mathcal{C}) \to \mathcal{C}$.

The following definition describes the weak equivalences, cofibrations, and fibrations of the injective model category structure on $\text{Fun}(I, \mathcal{C})$ provided it exists.

**Definition 13.1.**

1. A weak equivalence in $\text{Fun}(I, \mathcal{C})$ is a morphism $f$ such that $e_i(f)$ is a weak equivalence in $\mathcal{C}$ for every $i$ in $I$.
2. A cofibration in $\text{Fun}(I, \mathcal{C})$ is a morphism $f$ such that $e_i(f)$ is a cofibration in $\mathcal{C}$ for every $i$ in $I$.
3. A fibration is a morphism in $\text{Fun}(I, \mathcal{C})$ which has the right-lifting property with respect to trivial cofibrations.

Let $\mathcal{C}$ belong to the list

$$\{ \ast \text{Cat}_1, \ast \ast \text{Cat}_1, \ast \text{Cat}^+, \ast \ast \text{Cat}^+, \ast \text{pre} \text{Cat}_1, \ast \ast \text{pre} \text{Cat}_1 \}$$

and $I$ be a small category.

**Theorem 13.2.** The injective model category structure on $\text{Fun}(I, \mathcal{C})$ exists.

**Proof.** It is a non-trivial fact that the injective model category structure on a functor category $\text{Fun}(I, \mathcal{C})$ exists provided that the model category structure on the target $\mathcal{C}$ is combinatorial. The proof involves Smith’s theorem, see e.g. [Bek00, Thm. 1.7], [Lur09, Sec. A.2.6]. A textbook reference of the fact stated precisely in the form we need is [Lur09, Prop. A.2.8.2]. So in view of the second assertion of Theorem 9.2 the assertion of the Theorem follows for $\mathcal{C}$ in the list

$$\{ \ast \text{Cat}_1, \ast \ast \text{Cat}_1, \ast \text{Cat}^+, \ast \ast \text{Cat}^+, \ast \text{pre} \text{Cat}_1, \ast \ast \text{pre} \text{Cat}_1 \}.$$ 

It remains to discuss the case where $\mathcal{C}$ belongs to the list

$$\{ \ast \text{pre} \text{Cat}_1, \ast \ast \text{pre} \text{Cat}_1 \}.$$ 

In this case we employ a result Cisinski\(^{10}\) that the injective model category structure on a functor category $\text{Fun}(I, \mathcal{C})$ exist under the following conditions on a model category structure $(W, Cof, Fib)$ on a category $\mathcal{C}$:

1. $\mathcal{C}$ has small limits.
2. $\mathcal{C}$ is right proper, and
3. in $\mathcal{C}$ the class of cofibrations is closed under small limits.

\(^{10}\)I thank D. Ch. Cisinski for explaining this fact to me.
The proof is exactly same as the one of [Cis03, Thm. 6.16].

The category $C^{\ast}_{\text{pre}}$ is complete and hence has small limits. Furthermore, every (marked) pre-$C^{\ast}$-category is fibrant so that $C^{\ast}_{\text{pre}}$ is right-proper [Hir03, Cor. 13.1.3]. Finally, a limit of a diagram of injective maps of sets is injective, and the action of a limit of a diagram functors on objects is the limit of the diagram of maps induced on objects. Therefore a limit of cofibrations in $C^{\ast}_{\text{pre}}$ is again a cofibration. \hfill \Box

Let $C$ belong to the list

$$\{^*\text{Cat}_1, _*^\ast\text{Cat}_1, C^\ast\text{Cat}_1, C^\ast_+\text{Cat}_1, C^\ast_+\text{Cat}_1, C^\ast_+\text{Cat}_1\}.$$  

We have a functor $\tilde{G} \to \ast$ in $G$-categories (see Section 7.1 for notation). It induces a transformation of functors (see Convention 6.14 for notation)

$$\begin{align*}
\text{id} & \to \text{Fun}^\ast(\tilde{G}, -) : \text{Fun}(BG, C) \to \text{Fun}(BG, C).
\end{align*}$$

Proposition 13.3. The functor

$$\begin{align*}
\text{Fun}^\ast(\tilde{G}, -) : \text{Fun}(BG, C) \to \text{Fun}(BG, C)
\end{align*}$$

together with the natural transformation (13.1) is a fibrant replacement functor with respect to the injective model structure on $\text{Fun}(BG, C)$.

Proof. We use Remark 7.4 stating that $\text{Fun}^\ast(\tilde{G}, A) \cong \text{Fun}^a(\tilde{G}, A)$, where on the right-hand side we consider $A$ as a (marked) ($C$-linear) $\ast$-category. In this way we avoid a case-dependent discussion.

We must first show that for every object $A$ of $C$ the transformation (13.1) induces a weak equivalence

$$r : A \to \text{Fun}^\ast(\tilde{G}, A)$$

in $C$. To this end we must find an inverse up to (marked) unitary isomorphism of $r$ on the level of underlying objects in $C$. We define a (non $G$-equivariant) functor

$$e : \text{Fun}^\ast(\tilde{G}, A) \to A, \quad a \mapsto a(1), \quad e(f : a \to a') := (f(1) : a(1) \to a'(1)).$$

Then clearly $e \circ r = \text{id}_A$. We furthermore have a (marked) unitary isomorphism $r \circ e \to \text{id}_{\text{Fun}^\ast(\tilde{G}, A)}$ given on $a$ in $\text{Fun}^\ast(\tilde{G}, A)$ by the collection of (marked) unitary morphisms $(a(1) \to g) : a(1) \to a(g))_{g \in G}$.

In order to finish the proof we must show that $\text{Fun}^\ast(\tilde{G}, A)$ is fibrant. To this end we consider a square in $\text{Fun}(BG, C)$:

$$\begin{array}{ccc}
C & \xrightarrow{e} & \text{Fun}^\ast(\tilde{G}, A) \\
\downarrow{c} & & \downarrow{\text{id}} \\
D & \xrightarrow{\ast} & \\
\end{array}$$

61
where $C \to D$ is a trivial cofibration in $\text{Fun}(BG, C)$. We must show the existence of the diagonal lift.

We use the identification $\text{Fun}^2(BG, *) \simeq *$ (here $*$ denotes a final object in $C$) and the exponential law Proposition 7.5 in order to rewrite the problem as

$$\begin{array}{c}
C & \xrightarrow{\phi} & A \\
\downarrow & & \downarrow \\
D & \xrightarrow{\tilde{d}} & * \\
\end{array}$$

Since the underlying morphism of $c : C \to D$ is a trivial cofibration in $C$ it is injective on objects. We choose an inverse equivalence $d : D \to C$ (not necessarily $G$-invariant) up to (marked) unitary equivalence which is a precise inverse on the image of $c$. We can extend the composition

$$D \xrightarrow{d} C \to C \times \{1\} \to C_\sharp \tilde{G}$$

uniquely to a $G$-invariant morphism

$$\tilde{d} : D_\sharp \tilde{G} \to C_\sharp \tilde{G}.$$ 

Indeed, we set

$$\tilde{d}(D, g) := (g(d(g^{-1}(D))), g), \quad \tilde{d}(f : D \to D', g \to h) := gd(g^{-1}f)\sharp(g \to h).$$

The desired diagonal can now be obtained as the composition $\phi \circ \tilde{d}$. \hfill \qed

**Remark 13.4.** Let $(C, W)$ be a relative category. Then we can consider the localization

$$\ell : C \to C_\infty := C[W^{-1}]$$

in the realm of $\infty$-categories, see Remark 1.7. For a small category $I$ we let

$$\ell_I : \text{Fun}(I, C) \to \text{Fun}(I, C_\infty)$$

denote the functor given by post-composition with $\ell$ in (13.2).

The content of the following proposition is well-known since it provides the basic justification that, in the case of limits, $\infty$-categories and model categories yields equivalent homotopical constructions. But since we do not know a reference where it is stated in this ready-to-use form we will give a proof.

Let $(C, W)$ be a relative category and $I$ be a small category.

**Proposition 13.5.** Assume that $(C, W)$ extends to a simplicial model category with the following properties:

1. The injective model category structure on $\text{Fun}(I, C)$ exists.
2. All objects of $C$ are cofibrant.
Then for any fibrant replacement functor $r : \text{id}_{\text{Fun}(I,C)} \to R$ in the injective model category structure of $\text{Fun}(I,C)$ we have an equivalence of functors

$$\lim_I \circ \ell_I \simeq \ell \circ \lim_I \circ R : \text{Fun}(I,C) \to C_\infty.$$  

Proof. Since $(C,W)$ extends to a simplicial model category with weak equivalences $W$ and with all objects cofibrant we can express the mapping spaces in $C_\infty$ in terms of the simplicial mapping spaces $\text{Map}_C$ of $C$. More precisely, if $A$ is a cofibrant and $A'$ is a fibrant object of $C$, then by Remark 1.8 we have an equivalence of spaces

$$\text{Map}_{C_\infty}(\ell(A), \ell(A')) \simeq \ell_{\text{sSet}}(\text{Map}_C(A, A')).$$ (13.4)

We let $W_I$ denote the weak equivalences in the injective model category structure on $\text{Fun}(I,C)$. We then have the commuting diagram

$$
\begin{array}{ccc}
\text{Fun}(I,C) & \xrightarrow{\ell_I} & \text{Fun}(I,C_\infty) \\
\downarrow{\alpha} & & \downarrow{\beta} \\
\text{Fun}(I,C)[W_I^{-1}] & \xrightarrow{\ell_I} & \text{Fun}(I,C_\infty) \end{array}
$$ (13.5)

where the arrow $\beta$ is induced by the universal property of the localization functor $\alpha$, see Remark [17]. It is a crucial fact shown in [Cis, Prop. 7.9.2] that the functor $\beta$ is an equivalence.

For $A$ in $C$ and $B$ in $\text{Fun}(I,C)$ we then have the following chain of natural equivalences of spaces

$$\text{Map}_{C_\infty}(\ell(A), \ell(\lim_I R(B))) \xrightarrow{!} \ell_{\text{sSet}}(\text{Map}_C(A, \lim_I R(B))) \\
\simeq \ell_{\text{sSet}}(\text{Map}_{\text{Fun}(I,C)}(A, R(B))) \\
\simeq \text{Map}_{\text{Fun}(I,C)[W_I^{-1}]}(\alpha(A), \alpha(R(B))) \\
\xrightarrow{\beta} \text{Map}_{\text{Fun}(I,C_\infty)}(\ell_I(A), \ell_I(R(B))) \\
\xrightarrow{!!} \text{Map}_{\text{Fun}(I,C_\infty)}(\ell_I(A), \ell_I(B)) \\
\simeq \text{Map}_{\text{Fun}(I,C_\infty)}(\ell(A), \ell_I(B)) \\
\simeq \text{Map}_{C_\infty}(\ell(A), \lim_I \ell_I(B)).$$

For the equivalence marked by $!$ we use Assumption 2 that $\lim_I R(B)$ is fibrant, and [13.4]. For the equivalence marked by $!!$ we again use [13.4], but now for the functor category (note that all objects of the functor category are cofibrant in the injective model category structure, and that the latter has a simplicial extension), and that by assumption $R(B)$ is fibrant in the injective model category structure on $\text{Fun}(I,C)$. Finally, for the equivalence marked by $!!!$ we use that $\ell_I(r) : \ell_I \to \ell_I \circ R$ is an equivalence.

---

11 Alternatively, if one in addition assumes that the model category structure on $C$ is combinatorial, then one could cite [Lur09, Section 4.2.4], or better, [Lur17, Cor. 1.3.4.26] for this fact.
The natural equivalence
\[ \text{Map}_{\mathcal{C}_\infty}(\ell(A), \ell(\lim_i R(B))) \simeq \text{Map}_{\mathcal{C}_\infty}(\ell(A), \lim_i \ell(B)) \]
implies the asserted equivalence of functors.

If we assume in addition that \((\mathcal{C}, W)\) extends to a combinatorial model category, then Prop. 13.5 is an immediate consequence of [Lur17, 1.3.4.23].

Note that the assumption 13.5.2 that the objects of the model category extension of \((\mathcal{C}, W)\) are cofibrant comes in since we define \(\mathcal{C}_\infty\) as the localization of the whole category \(\mathcal{C}\) by the weak equivalences \(W\). If not all objects are cofibrant, then the correct definition of the underlying \(\infty\)-category \(\mathcal{C}_\infty\) of the model category would be \(\mathcal{C}^\nu(W^{-1})\) [Lur17, 1.3.4.15]. Below we will apply this proposition in the case \(I = BG\).

Let \(\mathcal{C}\) be a member of the list
\[ \{^*\text{Cat}_1, ^*\text{C Cat}_1, C^*\text{Cat}_1, C^*\text{Cat}_1, ^*\text{Cat}_1^+, ^*\text{C Cat}_1^+, C^*\text{Cat}_1^+, C^*\text{Cat}_1^+ \} \]
and \(A\) be an object of \(\text{Fun}(BG, \mathcal{C})\).

**Theorem 13.6.** We have an equivalence
\[ \lim_{BG} \ell_{BG}(A) \simeq \ell(\hat{A}^G) . \]

**Proof.** We want to apply Proposition 13.5. By Theorem 1.3 the relative category \((\mathcal{C}, W)\) extends to a simplicial model category. By Theorem 13.2 the injective model category structure on \(\text{Fun}(BG, \mathcal{C})\) exists. Finally, by an inspection of the definitions (Definition 9.1 for cofibrancy and, in addition, Proposition 9.5 and Corollary 9.9 for fibrancy), all objects of \(\mathcal{C}\) are cofibrant and fibrant.

We now apply Proposition 13.5 for the explicit version of \(R\) obtained in Proposition 13.3 and Definition 12.1 in order to get the equivalences
\[ \lim_{BG} \ell_{BG}(A) \simeq \ell(\lim_{BG}(\text{Fun}^\nu(\hat{G}, A))) \simeq \ell(\hat{A}^G) . \]

**Remark 13.7.** If \(\mathcal{C}\) belongs to the list
\[ \{^*\text{Cat}_1, ^*\text{C Cat}_1, C^*\text{Cat}_1, ^*\text{Cat}_1^+, ^*\text{C Cat}_1^+, C^*\text{Cat}_1^+ \} , \]
then by Theorem 1.3 in combination with Remark 1.5 we could base the proof of Theorem 13.6 on the version of the proof of Proposition 13.5 which only uses [Lur09, Section 4.2.4], see the footnote in the proof of 13.5.

In the remaining two cases, where \(\mathcal{C}\) belongs to the list
\[ \{C^*_\text{pre Cat}_1, C^*_\text{pre Cat}_1^+ \} , \]
we could then deduce the assertion of Theorem [13.6] as follows.

We use that Theorem [13.6] is true in the case of $\texttt{cCat}_1$. We let

$$F_{\text{pre}} : C_{\text{pre}}^{\ast} \texttt{Cat}_1^{(+)} \to \ast \texttt{cCat}_1^{(+)}$$

$$F_{\text{pre}} : C_{\text{pre}}^{\ast} \texttt{Cat}^{(+)} \to \ast \texttt{cCat}^{(+)}$$

denote the forgetful functors on the level of $1$- and of $\infty$-categories. They are inclusions of full subcategories fitting into adjunctions [5.5]. We conclude that the $\infty$-category $C_{\text{pre}}^{\ast} \texttt{Cat}^{(+)}$ is complete and the limit of an $I$-diagram in $C_{\text{pre}}^{\ast} \texttt{Cat}^{(+)}$ can be calculated by the formula

$$\lim I \simeq \text{Bd}^\infty \circ \lim I \circ F_{\text{pre}},$$

where the limit on the right-hand side is taken in $\ast \texttt{cCat}^{(+)}$.

For $A$ in $\text{Fun}(BG, C)$ we then have the chain of equivalences

$$\lim_{BG} \ell_{BG}(A) \overset{[13.6]}{\simeq} \text{Bd}^\infty(\lim_{BG} \ell_{BG}(A))$$

$$\overset{\text{Thm}[13.6]}{\simeq} \text{Bd}^\infty(\ell(F_{\text{pre}}(A)))$$

$$\overset{[13.4]}{\simeq} \ell(\text{Bd}^\infty(F_{\text{pre}}(A)))$$

$$\overset{[12.3]}{\simeq} \ell(\hat{A}^G).$$

At the marked morphisms we use that $F_{\text{pre}}$ and $\text{Bd}^\infty$ descend to the $\infty$-categories since they preserve weak equivalences. \[ \square \]

14 $X$-controlled objects and $G$-actions

In this section we provide an application of the homotopy theory of marked $\ast$-categories to the construction of equivariant coarse homology theories. We use this application as an opportunity to demonstrate the relevance of markings which are different from the canonical ones discussed in Example [2.21].

In Definition [14.10] we functorially associate to a bornological coarse space $X$ a marked $\ast$-category $V^+(X)$ of $X$-controlled objects (in an auxiliary $\ast$-category which is not reflected by the notation). The $\ast$-category $V^+(X)$ has a non-trivial marking reflecting the local structure of $X$.

We next consider a group $G$ acting on $X$, and hence on $V^+(X)$ by functoriality. In this case can consider $V^+(X)$ as an object of $\text{Fun}(BG, C^+)$, where $C$ is one of the categories of $\ast$-categories in the list $\{\ast \texttt{Cat}_1, \ast \texttt{cCat}_1, C^+ \texttt{Cat}_1\}$. The main result of the present section is Corollary [14.15] which explicitly identifies the limit

$$V^{G,+}(X) := \lim_{BG} \ell_{BG}(V^+(X)),$$
where \( \ell_{BG} \) is as in (1.4). Even if we forgot the marking at the end, the result would depend non-trivially on the marking of \( V^+(X) \), see Remark 14.17. This application is our main motivation to add the marked version of the theory.

In order to provide the context for the present section we first recall the category BornCoarse of bornological coarse spaces introduced in \[BE16\] as a basic framework for large-scale geometry.

**Definition 14.1.** A bornological coarse space is a triple \((X, B, C)\) consisting of a set \(X\) together with a coarse structure \(C\) and a bornology \(B\) which are compatible to each other.

Recall:

1. A coarse structure \(C\) on \(X\) is a subset of the power set \(\mathcal{P}(X \times X)\) which contains the diagonal and is closed under forming finite unions, subsets, compositions (see (14.3)) and inverses (see (14.4)). The elements of \(C\) are called entourages.
2. A bornology \(B\) on \(X\) is a subset of the power set \(\mathcal{P}(X)\) which is closed under forming finite unions, subsets, and which contains all one-point sets. The elements of \(B\) are called bounded subsets.
3. The coarse structure \(C\) and the bornology \(B\) are compatible to each other if for every \(B\) in \(B\) and \(U\) in \(C\) the \(U\)-thickening
   \[ U[B] := \{ x \in X \mid (\exists b \in B \mid (x, b) \in U) \} \]
   of \(B\) belongs again to \(B\).

**Definition 14.2.** A morphism \((X, C, B) \to (X', C', B')\) between bornological coarse spaces is a map of sets \(f : X \to X'\) which is proper (i.e., satisfies \(f^{-1}(B') \subseteq B\)) and controlled (i.e., satisfies \((f \times f)(C) \subseteq C')\).

We thus obtain the category BornCoarse of bornological coarse spaces and morphisms.

Let now \(G\) be a group.

**Definition 14.3.** A \(G\)-bornological coarse space is a bornological coarse space \((X, C, B)\) with an action of \(G\) by automorphisms such that \(C^G\) is cofinal in \(C\), i.e., for every \(U\) in \(C\) there exists \(V\) in \(C^G\) such that \(U \subseteq V\).

We obtain the category \(G\)BornCoarse of \(G\)-bornological coarse spaces and equivariant morphisms \[BEKW17\].

**Remark 14.4.** In this longer remark we explain why we wish to consider marked \(*\)-categories of controlled objects and its \(\infty\)-categorical \(G\)-orbits. Our main tool to study (equivariant) bornological coarse spaces are (equivariant) coarse homology theories \[BE16\], \[BEKW17\]. Let \(D\) be a stable \(\infty\)-category. A \(D\)-valued (equivariant) coarse homology theory is a functor

\[ E : (G)\text{BornCoarse} \to D \]

satisfying the following axioms:
1. coarse invariance
2. excision
3. vanishing on flasques
4. $u$-continuity.

We refer to [BE16] or [BEKW17] for the details which are not important for the present paper.

We propose the following ansatz for deriving an equivariant coarse homology theory from a non-equivariant one. The basic datum is a decomposition of a non-equivariant homology theory $E$ as a composition of functors

$$E : \text{BornCoarse} \xrightarrow{W} \mathcal{E} \xrightarrow{K} D. \quad (14.1)$$

The functor $W$ associates to a bornological coarse space $X$ a category $W(X)$ of $X$-controlled objects in the intermediate category $\mathcal{E}$. The idea is then to obtain an equivariant coarse homology theory as the composition

$$E^G : G\text{BornCoarse} \xrightarrow{\dagger} \text{Fun}(BG, \text{BornCoarse}) \xrightarrow{W^+} \text{Fun}(BG, \mathcal{E}^+) \xrightarrow{\text{lim}_{BG}} \mathcal{E}^+ \xrightarrow{!!} \mathcal{E} \xrightarrow{K} D. \quad (14.2)$$

Here $\mathcal{E}^+$ and $W^+$ are a marked versions of $\mathcal{E}$ and the functor $W$. The arrow marked by $\dagger$ is the natural inclusion which just disregards the additional condition on the coarse structures in Definition 14.3. The arrow marked by $!!$ forgets the marking.

Examples of coarse homology theories with the structure (14.1) are:

1. Coarse $K$-homology [BE16]: Here $\mathcal{E}$ is the $\infty$-category $C^*\text{Cat}$ of $C^*$-categories.
2. Coarse algebraic $K$-theory with coefficients in an additive category [BEKW17]: Here $\mathcal{E}$ is the $\infty$-category of additive categories obtained from the 1-category of additive categories by inverting exact equivalences.
3. Coarse algebraic $K$-theory with coefficients in a left exact category [BCKW]: Here $\mathcal{E}$ is the $\infty$-category $\text{Cat}_{\infty, \text{Lex}}^L$ of small pointed left-exact $\infty$-categories.

A priori it is not clear that the formula (14.2) produces an equivariant coarse homology theory, i.e., that $E^G$ satisfies the four axioms stated above. The verification of the axioms requires to identify

$$W^G,+(X) := \lim_{BG} W^+(X)$$

explicitly. In the papers on equivariant coarse homology theories mentioned above we actually constructed the functor $W^G,+$, and hence the corresponding equivariant coarse homology theories, in an ad-hoc manner.

In the present paper we consider the case where $\mathcal{E} = \mathcal{C}_\infty$ for $\mathcal{C}$ in the list

$$\{^*\text{Cat}_1, ^*\text{cCat}_1, C^*\text{Cat}_1\},$$

67
and $W \simeq \ell \circ V$. The main purpose of the present section is to describe the functor $V^+$ and to calculate $\lim_{BG} \ell_{BG}(V^+(X))$ explicitly (Corollary 14.15). Our result will serve as a reference for the verification that certain ad-hoc constructions of equivariant coarse homology theories considered in subsequent papers are indeed instances of the general construction (14.2).

We now prepare the definition of the functor $V^+$. Let $\hat{C}$ be star_category enriched in commutative monoids and $C \hookrightarrow \hat{C}$ be the inclusion of a full-subcategory such that the image is closed under isomorphisms and finite sums. The idea is that the objects in $\hat{C}$ can be large (e.g., that $\hat{C}$ has all small coproducts), and $C$ are the objects of $\hat{C}$ satisfying certain finiteness conditions.

We will assume that the monoid structure on the morphism sets is preserved by the involution $\ast$. Note that $C$ is a $\ast$-subcategory.

**Example 14.5.** Here are some examples:

1. Let $\tilde{\mathbf{Set}}$ be the $\ast$-category of sets and correspondences. For two sets $X, Y$ the set of morphisms from $X$ to $Y$ in $\tilde{\mathbf{Set}}$ is defined by

$$\text{Hom}_{\tilde{\mathbf{Set}}}(X, Y) := \mathcal{P}(Y \times X),$$

where for a set $S$ the symbol $\mathcal{P}(S)$ denotes the power set of $S$. If $U$ in $\mathcal{P}(Y \times X)$ and $V$ in $\mathcal{P}(Z \times Y)$ are two morphisms, then their composition $V \circ U$ in $\mathcal{P}(Z \times X)$ is defined by

$$V \circ U = \{(z, x) \in Z \times X \mid (\exists y \in Y \mid (z, y) \in V \& (y, x) \in U)\}.$$  \hfill (14.3)

The monoid structure on $\text{Hom}_{\tilde{\mathbf{Set}}}(X, Y)$ is given by the union of subsets of $\mathcal{P}(Y \times X)$. The empty set is the zero element of the monoid. Finally, the $\ast$-functor sends a correspondence $U$ in $\mathcal{P}(Y \times X)$ to

$$U^{-1} := \{(x, y) \mid (y, x) \in U\}$$  \hfill (14.4)

in $\mathcal{P}(X \times Y)$.

Note that if $X$ is a set, then for every subset $Y$ of $X$ we have a selfadjoint projection $\phi(Y) := \text{diag}_X \cap (Y \times Y)$ in $\text{End}_{\tilde{\mathbf{Set}}}(X)$ with image $Y$.

The $\ast$-category $\tilde{\mathbf{Set}}$ contains the full $\ast$-subcategory $\tilde{\mathbf{Set}}^{\text{fin}}$ of finite sets.

2. By linearizing the categories in Example 1 we get the $\mathbb{C}$-linear $\ast$-category $\text{Lin}_{\mathbb{C}}(\tilde{\mathbf{Set}})$ and its full subcategory $\text{Lin}_{\mathbb{C}}(\tilde{\mathbf{Set}}^{\text{fin}})$.

3. Let $A$ be a $C^*$-algebra. Then we can consider the $C^*$-categories $\text{Hilb}_A$ of Hilbert $A$-modules and its full subcategory $\text{Hilb}_A^{\text{fg}}$ of Hilbert $A$-modules with compact identity.
We now return to the general case. Let \( \hat{\mathcal{C}} \) be given and \( M \) be an object of \( \hat{\mathcal{C}} \). By \( \text{Proj}(M) \) we denote the selfadjoint idempotents in \( \text{End}(M) \) which have an image. If \( e \) belongs to \( \text{Proj}(M) \), then we let \( e(M) \to M \to e(M) \) denote some choice of a retraction diagram which presents \( e(M) \) as the image of \( e \). Note that \( e(M) \) is determined uniquely up to isomorphism.

Let \( X \) be a set and \( M \) be an object of \( \hat{\mathcal{C}} \).

**Definition 14.6.** A projection-valued measure on \( X \) is a map

\[ \phi : \mathcal{P}(X) \to \text{Proj}(M) \]

such that

1. \( \phi(X) = \text{id}_M \).
2. \( \phi(\emptyset) = 0 \).
3. For all subsets \( Y, Z \) of \( X \) we have \( \phi(Y) \circ \phi(Z) = \phi(Y \cap Z) \).
4. For all subsets \( Y, Z \) of \( X \) we have \( \phi(Y \cup Z) + \phi(Y \cap Z) = \phi(Y) + \phi(Z) \).

Let \( X \) be a bornological coarse space.

**Definition 14.7.** An \( X \)-controlled object in \( (\hat{\mathcal{C}}, \mathcal{C}) \) is a pair \((M, \phi)\) of an object \( M \) of \( \hat{\mathcal{C}} \) and a projection valued measure \( \phi : \mathcal{P}(X) \to \text{Proj}(M) \) such that \( \phi(B)(M) \) belongs to \( \mathcal{C} \) for all bounded subsets \( B \) of \( X \).

Since \( \phi(B)(M) \) is determined uniquely up to isomorphism and \( \mathcal{C} \) is closed in \( \hat{\mathcal{C}} \) under isomorphisms the last condition is unambiguous.

**Definition 14.8.** An \( X \)-controlled object in \( (\hat{\mathcal{C}}, \mathcal{C}) \) is determined on points if the sum \( \bigoplus_{x \in X} \phi(\{x\})(M) \) exists in \( \hat{\mathcal{C}} \) and the natural morphism \( \bigoplus_{x \in X} \phi(\{x\})(M) \to M \) is an isomorphism.

Let \( U \) be an entourage of \( X \) and \((B, B')\) be a pair of subsets of \( X \). We call this pair \( U \)-separated if \( U[B] \cap B' = \emptyset \).

We consider two \( X \)-controlled objects \((M, \phi)\) and \((M', \phi')\) in \( (\hat{\mathcal{C}}, \mathcal{C}) \).

**Definition 14.9.** A morphism \( A : (M, \phi) \to (M', \phi') \) is a morphism \( A : M \to M' \) in \( \hat{\mathcal{C}} \) such that there exists an entourage \( U \) of \( X \) such that for every \( U \)-separated pair \((B, B')\) of subsets of \( X \) we have \( \phi'(B') \circ A \circ \phi(B) = 0 \). We say that \( A \) is \( U \)-controlled.

If \( A : (M, \phi) \to (M', \phi') \) is a morphism of \( X \)-controlled objects, then so is \( A^* : (M', \phi') \to (M, \phi) \). Indeed, if \( A \) is \( U \)-controlled, then \( A^* \) is \( U^{-1} \)-controlled.

If \( A \) is \( U \)-controlled and \( A' \) is \( U' \)-controlled, then \( A \circ A' \) (if defined) is \( U \circ U' \)-controlled.
Definition 14.10. We let $V_{(\hat{C}, C)}(X)$ denote the $*$-category of $X$-controlled objects in $(\hat{C}, C)$ which are determined on points, and morphisms.

We let $V^+_{(\hat{C}, C)}(X)$ denote the marked $*$-category obtained from $V_{(\hat{C}, C)}(X)$ by marking all diag($X$)-controlled unitary morphisms.

If $\hat{C}$ is a $C$-linear $*$-category, then $V^+_{(\hat{C}, C)}(X)$ is equipped with the naturally induced $C$-linear structure.

We observe that the identities in $V_{(\hat{C}, C)}(X)$ are diag($X$)-controlled, and that the composition of two diag($X$)-controlled morphisms is again diag($X$)-controlled. This justifies our definition of the marking.

Remark 14.11. Dropping the condition determined on points leads to further interesting examples. We refer to the discussion in [BEKW17, Ex. 8.31].

Convention 14.12. We will simplify the notation and just write $V^+_{C}(X)$ for $V^+_{(\hat{C}, C)}(X)$.

In the present paper we will not discuss the functoriality in $C$.

Let $f : X \to X'$ be a morphism between bornological coarse spaces. It induces a morphism

$$f_* : V^+_{C}(X) \to V^+_{C}(X'), \quad f_*(M, \phi) := (M, \phi \circ f^{-1}), \quad f_*(A) := A.$$

We therefore get for every pair $(\hat{C}, C)$ functors

$$V^+_{C} : \text{BornCoarse} \to \text{Cat}^+_{(*)},$$

or

$$V^+_{C} : \text{BornCoarse} \to \text{C Cat}^+_{(*)}$$

in the $C$-linear $*$-category case.

Remark 14.13. Assume now that $\hat{C}$ is a $C^*$-category. As the example of Roe categories discussed in [BE16, Def. 7.47] shows we can not expect that $V_{C}(X)$ is again a $C^*$-category. The controlled propagation condition on the morphisms $(M, \phi) \to (M', \phi')$ described in Definition 14.9 determines a subspace of $\text{Hom}_{C}(M, M')$ which in general is not closed.

But it is a natural open question whether for a pre-$C^*$-category $C$ the category $V_{C}(X)$ is a pre-$C^*$-category. It is definitely a $C$-linear $*$-category.

Example 14.14. Let $A$ be a $C^*$-algebra and consider the $C^*$-category $\text{Hilb}_{A}$ of Hilbert-$A$-modules and bounded adjointable operators together with its subcategory $\text{Hilb}_{A}^{fg}$ of finitely generated modules.

In the following we extend the definition of Roe categories [BE16, Def. 7.47] (the case $A = \mathbb{C}$) to general $A$. 70
Let $X$ be a bornological coarse space. Then $V_{\text{Hilb}_A^f}(X)$ is a $\mathbb{C}$-linear $\ast$-category. We do not know whether it is a pre-$C^\ast$-category. But using the additional information that the objects of $V_{\text{Hilb}_A^f}(X)$ are Hilbert $A$-modules we can define a $C^\ast$-category by completing the morphism spaces in the natural norm, which could be different from the maximal norm. Indeed, if $(M, \phi)$ and $(M', \phi')$ are objects of $V_{\text{Hilb}_A^f}(X)$, then we have an inclusion

$$\text{Hom}_{V_{\text{Hilb}_A^f}(X)}((M, \phi), (M', \phi')) \subseteq \text{Hom}_{\text{Hilb}_A}(M, M').$$

(14.5)

We define the category $\bar{V}_{\text{Hilb}_A^f}(X)$ such that it has the same objects as $V_{\text{Hilb}_A^f}(X)$ and its morphism spaces are the closures of these subspaces in (14.5). This category inherits a $\ast$-operation. Using the characterization of $C^\ast$-categories as in Remark 2.15 it is easy to see that $\bar{V}_{\text{Hilb}_A^f}(X)$ is a $C^\ast$-category and that we have a morphism

$$V_{\text{Hilb}_A^f}(X) \to \bar{V}_{\text{Hilb}_A}(X)$$

(14.6)

of $\mathbb{C}$-linear $\ast$-categories. We have thus described a functor

$$\bar{V}_{\text{Hilb}_A^f} : \text{BornCoarse} \to C^\ast\text{Cat}_1.$$

We define the marked $C^\ast$-category $\bar{V}_{\text{Hilb}_A^f}^+$ by marking the morphisms in $\bar{V}_{\text{Hilb}_A^f}(X)$ which are images of $\text{diag}(X)$-controlled unitary morphisms under of the natural map (14.6). In this way we have constructed a functor

$$\bar{V}_{\text{Hilb}_A^f}^+ : \text{BornCoarse} \to C^\ast\text{Cat}_1^+.$$

For $A = \mathbb{C}$, up to the marking, this reproduces the definition in [BE16] of the $C^\ast$-category of $X$-controlled Hilbert spaces which are locally finite and determined on points.

After these examples for the functor $V^+$ we now come back to the general theory. We assume that $\mathcal{C}$ belongs to the list

$$\{ C^\ast\text{Cat}_1, C^\ast\text{Cat}_1^+, C^\ast_{\text{preCat}_1}, C^\ast\text{Cat}_1 \}.$$

We furthermore assume that we have a functor

$$V^+ : \text{BornCoarse} \to C^+$$

with the following properties:

1. There is a pair $(\mathcal{C}, \hat{\mathcal{C}})$ in $\mathcal{C}$ such that the functor associates to a bornological coarse space $X$ a category $V^+(X)$ in $C^+$ of $X$-controlled $\mathcal{C}$-objects $(M, \phi)$.

2. Morphisms $(M, \phi) \to (M', \phi')$ in $V^+(X)$ are morphisms $M \to M'$ in $\hat{\mathcal{C}}$ with certain properties. We require that all $\text{diag}(X)$-controlled unitary isomorphisms $M \to M'$ are morphisms in $V^+(X)$.
3. The functor sends a morphism \( f : X' \to X \) of bornological coarse spaces to the morphism \( f_* : \mathbf{V}^+(X') \to \mathbf{V}^+(X) \) in \( \mathcal{C}^+ \) given by \( f_*(M,\phi) := (M,\phi \circ f^{-1}) \) on objects and the identity on morphisms.

4. The marked morphisms \((M,\phi) \to (M',\phi')\) are the \( \text{diag}(X) \)-controlled unitary isomorphisms \( M \to M' \).

This subsumes all examples described above, in particular also the example \( \mathbf{V}_{\text{Hilb}}^+ \) introduced in Example 14.14.

Let \( G \) be a group and \( X \) be a bornological coarse space with a \( G \)-action. Then we can consider \( X \) as an object of the functor category \( \text{Fun}(BG, \text{BornCoarse}) \) and therefore, by functoriality, \( \mathbf{V}^+(X) \) as an object of \( \text{Fun}(BG, \mathcal{C}^+) \).

Recall the Definition 12.1 of the \( \hat{-}^G \) construction. We now specialize Theorem 13.6

**Corollary 14.15.** We have an equivalence

\[
\lim_{BG} \ell_{BG}(\mathbf{V}^+(X)) \simeq \ell((\mathbf{V}^+X)^G).
\]

**Example 14.16.** If \( \mathcal{C} \) belongs to the list \( \{^{*}\text{Cat},^{*}_c\text{Cat},^{*}\text{Cat}^1\} \), then using Remark 12.2 we can describe the object \( \hat{\mathbf{V}}^+(X)^G \) of \( \mathcal{C} \) explicitly as follows.

An object of \( \hat{\mathbf{V}}^+(X)^G \) is a triple \((M,\phi,\rho)\), where \((M,\phi)\) is an object of \( \mathbf{V}^+(X) \) and \( \rho \) is a unitary representation of \( G \) on \( M \) considered as an object of \( \hat{\mathcal{C}} \) such that

\[
\rho(g) \circ \phi(gY) \circ \rho(g^{-1}) = \phi(Y)
\]  
(14.7)

for all elements \( g \) of \( G \) and subsets \( Y \) of \( X \). This equation expresses the fact that \( \rho(g) : (M,\phi) \to (M,g\ast\phi) \) is a diag-controlled unitary in \( \mathbf{V}(X) \).

Morphisms in \( \hat{\mathbf{V}}^+(X)^G \) are just \( G \)-equivariant morphisms in \( \mathbf{V}^+(X) \).

Finally, the marked morphisms in \( \hat{\mathbf{V}}^+(X)^G \) are the marked \( G \)-equivariant morphisms in \( \mathbf{V}^+(X) \), i.e, the \( G \)-invariant \( \text{diag}(X) \)-controlled unitary morphisms.

After forgetting the marking this is exactly the description of the category \( \mathbf{V}^G(X) \) which would be taken in the ad-hoc definition of the \( G \)-equivariant version of coarse homology theory

\[
E := K \circ \ell \circ \mathbf{V}^G
\]

(see [BFJR04], [BEKW17, Sec. 8.6], [BC, Sec. 3.2]).

**Remark 14.17.** In Example 14.16 it is crucial to work with marked categories. If one forgets the marking and then takes \( G \)-invariants, then the condition (14.7) is no longer satisfied and \( \hat{\mathbf{V}}(X)^G \) differs from \( \mathbf{V}^G(X) \).  

---

12I thank Christoph Winges for pointing out a corresponding mistake in an earlier version of this paper.
15 Infinity-categorical $G$-orbits

Let $\mathcal{C}$ be a model category and $I$ be a small category. In the following definition we describe the weak equivalences, cofibrations, and fibrations of the projective model category structure on $\text{Fun}(I, \mathcal{C})$ provided it exists. Recall, that for $i$ in $I$ we have the evaluation functor $e_i : \text{Fun}(I, \mathcal{C}) \to \mathcal{C}$.

**Definition 15.1.**

1. A weak equivalence in $\text{Fun}(I, \mathcal{C})$ is a morphism $f$ such that $e_i(f)$ is a weak equivalence in $\mathcal{C}$ for every $i$ in $I$.

2. A fibration in $\text{Fun}(I, \mathcal{C})$ is a morphism $f$ such that $e_i(f)$ is a fibration in $\mathcal{C}$ for every $i$ in $I$.

3. A cofibration is a morphism in $\text{Fun}(I, \mathcal{C})$ which has the left-lifting property with respect to trivial fibrations.

It is known (see e.g. [Hir03, Thm. 11.6.1]) that the projective model category structure on $\text{Fun}(I, \mathcal{C})$ exists if the model category structure on $\mathcal{C}$ is cofibrantly generated.

**Remark 15.2.** This remark is similar to Remark 13.4. Let $(\mathcal{C}, W)$ be relative category and $I$ be a small category. As before we let $\ell : \mathcal{C} \to \mathcal{C}_\infty := \mathcal{C}[W^{-1}]$ be the localization and $\ell_I : \text{Fun}(I, \mathcal{C}) \to \text{Fun}(I, \mathcal{C}_\infty)$ be the induced functor. For an object $C$ in $\text{Fun}(I, \mathcal{C})$ we want to calculate the colimit $\text{colim}_I \ell_I(C)$ in $\mathcal{C}_\infty$ using model categorical methods. The following proposition is the analog of Proposition 13.5. Its content is well-known, but we do not have a reference where it is stated in this ready-to-use form.

**Proposition 15.3.** Assume that $(\mathcal{C}, W)$ extends to a combinatorial model category. Then for any cofibrant replacement functor $l : L \to \text{id}_{\text{Fun}(I, \mathcal{C})}$ in the projective model category structure of $\text{Fun}(I, \mathcal{C})$ we have an equivalence of functors

$$\text{colim}_I \circ \ell_I \simeq \ell \circ \text{colim}_I \circ L : \text{Fun}(I, \mathcal{C}) \to \mathcal{C}_\infty.$$

**Proof.** We shall sketch a proof which is completely analogous to the proof of Proposition 13.5. Since a combinatorial model category structure is in particular cofibrantly generated the projective model category structure on $\text{Fun}(I, \mathcal{C})$ exists. It is again combinatorial [Lur09 Prop. A.2.8.2].

We again have the commuting diagram (13.5) where the arrow $\beta$ is an equivalence. For a fibrant object $B$ in $\mathcal{C}$ and $C$ in $\text{Fun}(I, \mathcal{C})$ we then have the following chain of natural
equivaleces of spaces

\[
\text{Map}_{\infty}(\ell(\text{colim} \, L(C)), \ell(B)) \cong \ell_\text{sSet}(\text{Map}_C(\text{colim} \, L(C), B)) \\
\cong \ell_\text{sSet}(\text{Map}_{\text{Fun}(I,C)}(L(C), B)) \\
\cong \alpha(L(C)), \alpha(B)) \\
\cong \text{Map}_{\text{Fun}(I,C)}(\ell_1(L(C)), \ell_1(B)) \\
\cong \text{Map}_{\text{Fun}(I,\infty)}(\ell_1(L(C)), \ell_1(B)) \\
\cong \text{Map}_{\text{Fun}(I,\infty)}(\ell_1(L(C)), \ell(B)) \\
\cong \text{Map}_{\text{Fun}(I,\infty)}(\ell_1(L(C)), \ell(B)) \\
\cong \text{Map}_{\infty}(\text{colim} \, \ell_1(C), \ell(B)) \\
\]

with the same justifications of the equivalences as in the proof of Proposition 13.5. For the equivalences marked by ! and !! we use that the model category structures on \(C\) and the functor category are combinatorial so that we still can apply Remark 1.8 in order to justify the equivalence 13.4 (note that in the projective model category structure on \(\text{Fun}(I,C)\) we can not expect that all objects are cofibrant), where we now have to use the existence of functorial factorizations and [Lur17, Rem. 1.3.4.16]. Note that \(\text{colim}_I L(C)\) is cofibrant in \(C\).

The natural equivalence

\[
\text{Map}_{\infty}(\ell(\text{colim} \, L(C)), \ell(B)) \cong \text{Map}_{\infty}(\text{colim} \, \ell_1(C), \ell(B))
\]

for all fibrant \(B\) implies the asserted equivalence of functors.

Alternatively, the assertion of Prop. 15.3 is an immediate consequence of [Lur17, 1.3.4.24].

We now assume that \(C\) belongs to the list

\[
\{ *\text{Cat}, *\text{cCat}, C^* \text{Cat}, \text{Cat}^+, *\text{cCat}^+, C^* \text{Cat}^+ \}.
\]

Remark 15.4. We must exclude the pre-\(C^*\)-category cases since we do not know that the corresponding model categories are combinatorial.

The relative category \((C,W)\) extends to a combinatorial model category (Theorem 1.3 and Remark 1.5) in which all objects are cofibrant and fibrant. Consequently the projective model category structure on \(\text{Fun}(BG,C)\) exists and Proposition 15.3 applies to \((C,W)\).}

Recall the Definition 7.1 of the groupoid \(\tilde{G}\). Furthermore recall the Convention 6.14 concerning the usage of \(\sharp\). We consider the functor

\[
L := -\sharp \tilde{G} : \text{Fun(BG,C)} \to \text{Fun(BG,C)}
\]

together with the transformation \(L \to \text{id}_{\text{Fun}(BG,C)}\) induced by the morphism of \(G\)-groupoids \(\tilde{G} \to \ast\).
Lemma 15.5. The functor $L$ together with the transformation $L \to \text{id}_{\text{Fun}(BG, C)}$ is a cofibrant replacement functor for the projective model category structure on $\text{Fun}(BG, C)$.

Proof. Since $\tilde{G} \to \text{id}$ is an (non-equivariant) equivalence of groupoids and for every object $D$ in $\text{Fun}(BG, C)$ the functor $D^\#_{\text{Grpd}}$ from groupoids to $C$ preserves unitary equivalences (see the proof of Lemma [10.1]), the morphism $D^\#_{\text{Grpd}} \tilde{G} \to D$ is a weak equivalence. We must show that $L(D)$ is cofibrant. To this end we consider the lifting problem

$$
\begin{array}{ccc}
\emptyset & \rightarrow & A \\
\downarrow & & \downarrow f \\
D^\#_{\text{Grpd}} \tilde{G} & \rightarrow & B
\end{array}
$$

where $f$ is a trivial fibration in $C$. Since $f$ is surjective on objects we can find an inverse equivalence (possibly non-equivariant) $g : B \to A$ for $f$ such that $f \circ g = \text{id}_B$. The map $D^\#_{\text{Grpd}}[1] \overset{u}{\rightarrow} B \overset{g}{\rightarrow} A$ can uniquely be extended to an equivariant morphism $c$ which is the desired lift. □

If $C$ is an object of $C$, then by $C$ we denote the object of $\text{Fun}(BG, C)$ given by $C$ with the trivial action of $G$.

We assume that $C$ belongs to the list

$$\{\ast \text{Cat}_1, \ast_C \text{Cat}_1, C^* \text{Cat}_1, \ast \text{Cat}_1^+, \ast_C \text{Cat}_1^+, C^* \text{Cat}_1^+\}.$$

Let $C$ be an object of $C$. Note that $BG$ is a groupoid.

Theorem 15.6. We have an equivalence

$$\text{colim}_{BG} \ell_{BG}(C) \simeq \ell(C^*_{\text{Grpd}} BG).$$

Proof. By Proposition [15.3] and Lemma [15.5] we have an equivalence

$$\text{colim}_{BG} \ell_{BG}(C) \simeq \ell(\text{colim}_{BG} C^*_{\text{Grpd}} \tilde{G}).$$

(15.1)

So it remains to calculate the colimit $\text{colim}_{BG} C^*_{\text{Grpd}} \tilde{G}$ in $C$. To this end will show that the functor $C^*_{\text{Grpd}} \rightarrow \text{Grpd}_1$ commutes with colimits and calculate that $\text{colim}_{BG} \tilde{G} \simeq BG$.

Let $A$ be an object of $C$. For a second object $D$ in $C$ we let $\text{Fun}_C(A, D)_+$ denote the subgroupoid of the functor category $\text{Fun}_C(A, D)$ of all functors and (marked) unitary isomorphisms.

Lemma 15.7. We have an adjunction

$$A^*_{\text{Grpd}} : \text{Grpd}_1 \rightleftarrows C : \text{Fun}_C(A, -)_+.$$

75
Proof. For $D$ in $C$ and $G$ in $\text{Grpd}_1$ we construct a natural bijection

$$\text{Hom}_C(A^\sharp G, D) \cong \text{Hom}_{\text{Grpd}_1}(G, \text{Fun}_C(A, D)_+) .$$

This bijection sends a morphism $\Phi$ in $\text{Hom}_C(A^\sharp G, D)$ to $\Psi$ in $\text{Hom}_{\text{Grpd}_1}(G, \text{Fun}_C(A, D)_+)$. Let $\Phi$ be given. We let $g, h$ denote objects of $G$ and $\phi : g \to h$ a be morphism. Then we define $\Psi$ by

$$\Psi(g)(a) := \Phi(a, g), \quad \Psi(g)(f) := \Phi(f, \text{id}_g), \quad \Psi(\phi) := (\Phi(\text{id}_a, \phi))_{\alpha \in A} .$$

Here $a$ is an object of $A$ and $f$ is a morphism in $A$. Observe that $\Psi(\phi)$ is a unitary isomorphism since $\Phi$ is compatible with the involution and $\phi$ is a unitary isomorphism. In the marked case, if $f$ is marked, then $\Psi(g)(f)$ is marked since $(f, \text{id}_g)$ is marked in $A^\sharp G$ and $\Phi$ preserves marked morphisms. Furthermore, $\Psi(\phi)$ is implemented by marked isomorphisms.

Vice versa, let $\Psi$ be given. Then we define

$$\Phi(a, g) := \Psi(g)(a), \quad \Phi(f, \phi) := \Psi(\phi)_a \circ \Psi(g)(f) .$$

This formula determines $\Phi$ on the generators of the morphisms. It can be extended by linearity (in the $C$-linear cases) and continuity (in the $C^\ast$-cases).

Corollary 15.8. We have an adjunction

$$C^\sharp \dashv : \text{Fun}(BG, \text{Grpd}_1) \to \text{Fun}(BG, C) : \text{Fun}_{\text{Fun}(BG, C)}(C, -)_+ .$$

Since $C^\sharp \dashv$ is a left-adjoint functor it commutes with colimits. Consequently we have an isomorphism

$$\text{colim}_{BG} \left( C^\sharp \tilde{G} \right) \cong C^\sharp \left( \text{colim}_{BG} \tilde{G} \right) . \quad (15.2)$$

Lemma 15.9. We have an isomorphism $\text{colim}_{BG} \tilde{G} \cong BG$.

Proof. We check the universal property of the colimit. Let $K$ be any groupoid. Then we have a natural bijection

$$\text{Hom}_{\text{Fun}(BG, \text{Grpd}_1)}(\tilde{G}, K) \cong \text{Hom}_{\text{Grpd}_1}(BG, K) .$$

This bijection sends $\Phi$ in $\text{Hom}_{\text{Fun}(BG, \text{Grpd}_1)}(\tilde{G}, K)$ to the morphism $\Psi$ in $\text{Hom}_{\text{Grpd}_1}(BG, K)$ given by

$$\Psi(*) := \Phi(1), \quad \Psi(g) := \Phi(1 \to g) .$$

If $\Psi$ is given, then we define $\Phi$ by

$$\Phi(g) := \Psi(*), \quad \Phi(g \to h) := \Psi(1 \to h) .$$

□
The assertion of Theorem 15.6 now follows from a combination of the relations (15.1), (15.2), and Lemma 15.9.

In the following we discuss an application of Theorem 15.6 to the calculation of the values of an induction functor $J^G$ (see Definition 15.10) from $C$ to functors from the orbit category $\text{Orb}(G)$ of $G$ to $C_\infty$.

The objects of $\text{Orb}(G)$ are the transitive $G$-sets, and its morphisms are equivariant maps. We can consider the underlying set of $BG$ as a transitive $G$-set with respect to the right action. One can then identify $\text{End}_{\text{Orb}(G)}(G)$ with the group $G$ acting by left-multiplication. We therefore get a fully faithful functor

$$j : BG \to \text{Orb}(G)$$

which sends the unique object of $BG$ to the transitive $G$-set $G$, and which identifies the group $\text{End}_{BG}(pt)$ (given by $G$) with the group $\text{End}_{\text{Orb}(G)}(G)$ as described above.

If $C_\infty$ is a presentable $\infty$-category (or sufficiently cocomplete), then we get an adjunction

$$j_! : \text{Fun}(BG, C_\infty) \rightleftarrows \text{Fun}(\text{Orb}(G), C_\infty) : j^* ,$$

where $j^*$ is the restriction functor along $j$.

We now assume that $C$ belongs to the list

$$\{^*\text{Cat}_1, ^C\text{Cat}_1, ^*\text{Cat}_1^+, ^C\text{Cat}_1^+, C^*\text{Cat}_1^+\} .$$

Then the corresponding $\infty$-category $C_\infty$ is presentable by Corollary 15.9 so that (15.3) applies.

**Definition 15.10.** We define the induction functor $J^G$ as the composition

$$J^G : C \xrightarrow{(-)} \text{Fun}(BG, C) \xrightarrow{\ell_{BG}} \text{Fun}(BG, C_\infty) \xrightarrow{j_!} \text{Fun}(\text{Orb}(G), C_\infty) .$$

For a subgroup $H$ of $G$ we consider $H\backslash G$ with the action of $G$ by right multiplication as an object of $\text{Orb}(G)$.

**Proposition 15.11.** We have an equivalence

$$J^G(C)(H\backslash G) \simeq \ell(C^\sharp BH) .$$

**Proof.** The functor $j_!$ is a left Kan-extension functor. The point-wise formula for the left Kan-extension gives an equivalence

$$J^G(C)(H\backslash G) \simeq j_!(\ell_{BG}(C))(H\backslash G) \simeq \text{colim}_{BG/(H\backslash G)} \ell_{BG}(C) .$$
The functor $BH \to BG/(H\setminus G)$ which sends the object $pt$ to the projection $G \to H\setminus G$ and the element $h$ of $H = \text{End}_{BH}(pt)$ to the morphism in $BG/(H\setminus G)$ given by left-multiplication by $h$ is an equivalence of categories. Consequently, we get an equivalence

$$\text{colim}_{BG/(H\setminus G)} \ell_{BG}(C) \simeq \text{colim}_{BH} \ell_{BH}(C)^{Thm.15.6} \simeq \ell(C_\sharp BH).$$

(15.5)

In the following examples we apply Proposition 15.11 to the construction of equivariant $K$-theory functors. Let $S$ be a stable $\infty$-category, e.g., the category of spectra. A Bredon-type $G$-equivariant $S$-valued homology theory is determined by a functor

$$\text{Orb}(G) \to S.$$ (see e.g. [DL98]). If $K : C_\infty \to S$ is some functor and we fix an object $C$ in $C$, then we can define such a functor by precomposing with the induction functor. We set

$$K^G_C := K \circ J^G(C) : \text{Orb}(G) \to S.$$ By Proposition 15.11 the values of this functor are given by

$$K^G_C(H\setminus G) \simeq K(\ell(C_\sharp BH)).$$ (15.6)

Example 15.12. We let $C = *_{\mathbb{C}}\text{Cat}_1$ and $K : *_{\mathbb{C}}\text{Cat}_1 \to \text{Sp}$ be the algebraic $K$-theory functor. The latter is defined as the composition

$$K : *_{\mathbb{C}}\text{Cat} \xrightarrow{\mathcal{F}} \text{preAdd} \xrightarrow{(-)_\oplus} \text{Add} \xrightarrow{K_{\text{alg}}} \text{Sp}.$$ (15.7)

Here $\text{preAdd}$ and $\text{Add}$ are the $\infty$-categories of preadditive and additive categories obtained from the corresponding 1-categories by inverting the exact equivalences. The forgetful functor $\mathcal{F}$ takes the underlying preadditive category of a $\mathbb{C}$-linear $*$-category, $(-)_\oplus$ is the additive completion functor (the left-adjoint to the inclusion $\text{Add} \to \text{preAdd}$), and $K_{\text{alg}}$ is the $K$-theory functor for additive categories. We refer to [BEKW] for further details.

We now fix the object classifier object $\Delta^0$ of $*_{\mathbb{C}}\text{Cat}$ (given by the $\mathbb{C}$-linear $*$-category associated to the $*$-algebra $\mathbb{C}$). Then we get the functor

$$K^G_{\Delta^0} : \text{Orb}(G) \to \text{Sp}.$$ (15.8)

Let $K_{\text{ring}} : \text{Ring} \to \text{Sp}$ be the algebraic $K$-theory functor for rings given in terms of $K_{\text{alg}}$ as the composition

$$K_{\text{ring}} : \text{Ring} \to \text{preAdd} \xrightarrow{(-)_\oplus} \text{Add} \xrightarrow{K_{\text{alg}}} \text{Sp},$$ (15.8)
where the first functor interprets a ring as a pre-additive category with one object. Then we see that $K_{\Delta^0}^G$ has the values

$$K_{\Delta^0}^G(H\backslash G) \simeq K_{\text{ring}}^\text{alg}(\mathbb{C}[H]).$$

Indeed,

$$K_{\Delta^0}^G(H\backslash G) \overset{(15.5)}{\simeq} K(\ell(\Delta^0_\sharp BH)) \overset{(15.13)}{\simeq} K(\ell(\mathbb{C}[H])) \overset{(15.7)}{\simeq} K_{\text{ring}}^\text{alg}(\mathbb{C}[H]).$$

We see that $K_{\Delta^0}^G$ provides a categorical construction of a functor which can be compared with the usual equivariant algebraic K-theory functor as considered e.g. in [DL98, Sec. 2].

**Example 15.13.** We let $\mathcal{C} = C^*\text{Cat}_1$ and $K_1^{\text{top}} : C^*\text{Cat}_1 \to \text{Sp}$ be the topological K-theory functor for $C^*$-categories. We refer [BE16, Sec. 7.5] for a construction of such a functor as a composition

$$K_1^{\text{top}} : C^*\text{Cat}_1 \xrightarrow{A^f} C^*\text{Alg} \xrightarrow{K_{C^*\text{Alg}}^{\text{top}}} \text{Sp},$$

where $A^f$ is the functor which associates to a $C^*$-category the free $C^*$-algebra generated by it, and $K_{C^*\text{Alg}}^{\text{top}}$ is the usual topological K-theory functor for $C^*$-algebras. The subscript 1 indicates that the functor is defined on the 1-category of $C^*$-categories. In particular, by [BE16, Cor. 7.44] the functor $K_1^{\text{top}}$ sends unitary equivalences of $C^*$-categories to equivalences of spectra and therefore has an essentially unique factorization $K^{\text{top}}$ as in

$$\xymatrix{ C^*\text{Cat}_1 \ar[rr]^{K_1^{\text{top}}} \ar[dr]_{\ell} & & \text{Sp} \ar[dl]^{K^{\text{top}}} \ar[dl]^{K^{\text{top}}} \ar[dl]^{K^{\text{top}}} \ar[dr]^{K^{\text{top}}}}$$

We again fix the object classifier object $\Delta^0$ in $C^*\text{Cat}_1$ and consider the functor

$$K_{\Delta^0}^{\text{top},G} : \text{Orb}(G) \to \text{Sp}.$$  

We then see that $K_{\Delta^0}^{\text{top},G}$ has the values

$$K_{\Delta^0}^{\text{top},G}(H\backslash G) \simeq K_{C^*\text{Alg}}^{\text{top}}(C_0^*(H)).$$

Indeed,

$$K_{\Delta^0}^{\text{top},G}(H\backslash G) \overset{(15.5)}{\simeq} K^{\text{top}}(\ell(\Delta^0_\sharp BH)) \overset{(15.13)}{\simeq} K^{\text{top}}(\ell(C_0^*(H))) \overset{(15.7)}{\simeq} K_{C^*\text{Alg}}^{\text{top}}(C_0^*(H)), $$

where the last equivalence follows from an inspection of the definition of the K-theory functor $K^{\text{top}}$. We again see that $K_{\Delta^0}^{\text{top},G}$ provides a categorical construction of a functor which can be compared with the topological K-theory functors as considered in [DL98, Sec. 2]. But note that our functor involves the maximal group $C^*$-algebra, while the functor constructed in [DL98] involves the reduced group $C^*$-algebra.  

\textsuperscript{13}Note that we have only discussed the values, not the action of the functor on morphisms.
