This work mainly presents a preliminary design for a pendulum experiment with both the source mass and the test mass in a striped pattern to amplify the Lorentz-violation signal, since the signal is sensitive to edge effects.

1. Introduction

Studying violations of local Lorentz invariance in the spacetime theory of gravity is a way to probe General Relativity. To search for Lorentz violation in pure gravity, some short-range experiments\textsuperscript{1–3} such as testing the gravitational inverse-square law using a torsion pendulum were performed and the data analyzed for a Lorentz-violation signal. In this work, we mainly present a special design for a pendulum experiment to enhance the sensitivity to the violation signal, which has not yet been detected.

2. Starting point of the new design

Lorentz-invariance violation in the pure-gravity sector with quadratic couplings of the Riemann curvature has been described quantitatively by the Standard-Model Extension (SME).\textsuperscript{1,4} Using the effective field technique, the coupling introduces a correction for the Newton gravity, which depends on time and orientation. Corresponding to the gravitational potential, the correction can be written as:

\[ V_{LV}(\vec{x}) = -G \frac{m_1 m_2}{|\vec{x}|^3} \tilde{k}(\vec{x}, T), \]  

(1)

with

\[ \tilde{k}(\vec{x}, T) \equiv \frac{2}{3} (\bar{k}_{\text{eff}})_{jkjk} - 9 (\bar{k}_{\text{eff}})_{jklm} \dot{x}^j \dot{x}^k \dot{x}^l \dot{x}^m + \frac{15}{2} (\bar{k}_{\text{eff}})_{jklm} \dot{x}^j \dot{x}^k \dot{x}^l \dot{x}^m. \]  

(2)
Here, \( m_1 \) and \( m_2 \) represent two point masses, and \( \vec{x} \) is the separation between them. The quantity \( \hat{x}^j \) is the projection of the unit vector \( \vec{x} \) along the \( j \)th direction. The coefficient \( (\bar{k}_{\text{eff}})_{jklm} \) for Lorentz violation has 15 independent components, as it is totally symmetric with indices \( j, k, l, m \) ranging over the three spatial directions.

As discussed in Ref. 5, shape and edge effects play an important role in determining the sensitivity of the experiment to the coefficients for Lorentz-invariance violation:

\[
\tau_{LV} \sim \varepsilon \Delta C(\bar{k}_{\text{eff}})_{jklm},
\]

where \( \varepsilon \) represents the edge effect, which is related to the geometrical parameters of the test and source masses. To derive an amplified experimental sensitivity to the Lorentz-violation signal, \( \varepsilon \) should be designed as large as possible. However, for our pendulum experiment, we have to work within the maximum capability of the fiber.

3. Theoretical analysis for the new design

According to Eq. (2), the violation coefficients \( (\bar{k}_{\text{eff}})_{jklm} \) are different in different frames. Thus, the Sun-centered frame is usually adopted as the canonical frame to report the results from experiments searching for a Lorentz-violation signal, since the coefficients can be regarded as constant on the scale of the solar system. The violation coefficients \( (\bar{k}_{\text{eff}})_{JKLM} \) in the Sun-centered frame can be connected with the coefficients \( (\bar{k}_{\text{eff}})_{jklm} \) in the laboratory frame by the rotation matrix \( R^{jJ} \):

\[
(\bar{k}_{\text{eff}})_{jklm} = R^{jJ} R^{kK} R^{lL} R^{mM} (\bar{k}_{\text{eff}})_{JKLM},
\]

where \( R^{jJ} \) involves \( \omega_{\odot} \approx 2\pi/(23\text{ h }56\text{ min}) \). Thus, Eq. (2) can be expressed as a Fourier series in the sidereal time \( T \) as:

\[
\bar{k}(\hat{x}, T) = c_0 + \sum_{m=1}^{4} [c_m \cos(m\omega_{\odot} T) + s_m \sin(m\omega_{\odot} T)]
\]

through Eqs. (2) and (4). The nine Fourier amplitudes \((c_0, c_m, s_m)\) are functions of \( (\bar{k}_{\text{eff}})_{JKLM} \). We reassemble the \( (\bar{k}_{\text{eff}})_{JKLM} \) (15 dimensions), and redefine the violation coefficients as \( \bar{k}_j \) (15 dimensions). By introducing \( \bar{k}_j \), the space \( (\bar{k}_{\text{eff}})_{JKLM} \) is decomposed into 5 subspaces, in which different harmonics of \( \omega_{\odot} \) for the Lorentz-violation signal are linked to different subspaces, such as:

\[
c_0 = \alpha_0 \bar{k}_0 + \alpha_1 \bar{k}_1 + \alpha_2 \bar{k}_2.
\]
Fig. 1. The I-shape torsion pendulum. $W_{t1}$ and $W_{s1}$ represent the test mass and source mass, respectively. The masses are in the striped geometry (a) and in the checkered geometry (b).

We find $c_0$ is linked to $k_0, k_1, k_2$, and the other four harmonics of $\omega_{\parallel}$ correspond to the other four subspaces, respectively. Thus, for the Lorentz-violation torque,

$$\tau_{LV} = G \rho_1 \rho_2 \int dV_1 dV_2 \frac{\partial \bar{k}(\hat{r}, T)}{\partial \theta} r^3 = \Lambda_j \bar{k}_j. \quad (7)$$

Here, the transfer coefficient $\Lambda_j$ is related to $\alpha_j$ and the geometrical parameters of the test mass and source mass, and it includes edge effects as described by $\varepsilon$ in Eq. (3). According to Eqs. (5)-(7), one can seek a special design for the experiment to satisfy the particular research requirements. For example, to probe the Lorentz-violation coefficients $\bar{k}_0, \bar{k}_1$ and $\bar{k}_3$ bet-
ter, one can design the test mass and source mass to make $\Lambda_0$, $\Lambda_1$ and $\Lambda_2$ larger.

4. Experimental design

The experimental schematic is similar to that in testing the inverse-square law for HUST-2011 (see Fig. 2 in Ref. 5), but the geometrical parameters here are designed differently to amplify the violation signal. We analyzed two upgraded designs (see Fig. 1) for the torsion pendulum. In one, the shape of the masses involves a striped geometry (see Fig. 1(a)), and in the other it involves a checkered geometry (see Fig. 1(b)). For the test mass $W_{t1}$ and the source mass $W_{s1}$ in the two designs, the gray part and white part represent tungsten and glass, respectively. Comparing the results of numerical simulation, we find the first design (striped geometry) is the better option to increase the Lorentz-violation signal.

5. Summary

Theoretically, we decomposed the 15 Lorentz-violation coefficients into five parts, with different harmonics of the violation signal corresponding to different parts, which helps to perform the special experimental design required to study a certain violation coefficient. In addition, we proposed a design to search for Lorentz violation at higher sensitivity, in which the masses are in a striped pattern.
