Abstract

The generic googly amplitudes in gauge theory are computed by using the Cachazo-Svrcek-Witten approach to perturbative calculation in gauge theory and the results are in agreement with the previously well-known ones. Within this approach we also discuss the parity transformation, charge conjugation and the dual Ward identity. We also extend this calculation to include fermions and the googly amplitudes with a single quark-anti-quark pair are obtained correctly from fermionic MHV vertices. At the end we briefly discuss the possible extension of this approach to gravity.

1 Introduction

Recently Witten [1] found a deep connection between the perturbative gauge theory and string theory in twistor space [2]. Based on this work, Cachazo,

∗Supported in part by fund from the National Natural Science Foundation of China with grant Number 90103004.
Svrcek and Witten reformulated the perturbative calculation of the scattering amplitudes in Yang-Mills theory by using the off shell MHV vertices [3]. The MHV vertices they used are the usual tree level MHV scattering amplitudes in gauge theory [4, 5], continued off shell in a particular fashion as given in [3]. (For references on perturbative calculations, see for example [6].) The 2 dimensional origin of the MHV amplitudes in gauge theory was first given in [11]. Some sample calculations were done in [3], sometimes with the help of symbolic manipulation. The correctness of the rules was partially verified by reproducing the known results for small number of gluons [6].

In a previous work [12] (for recent works, see [13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29]), by following the new approach of [3], one of the authors computed the exceptionally simple amplitudes with two positive helicity gluons and an arbitrary number of negative helicity ones, called googly amplitudes in [3]. These amplitudes were calculated from the string theory in [13]. In the special case when the two positive helicity particles are adjacent, the result was shown to be in agreement with the well-known result [4]. In this paper we will calculate the generic googly amplitudes. By reproducing the previously well known results, our calculation gives a quite strong support to the Cachazo-Svrcek-Witten (CSW for short) proposal.

Although these calculations gave strong support to the CSW approach to the perturbative calculation in gauge theory, a direct proof for the equivalence to the usual Feynman rules seems hopeless. On the other hand, the twistor string theory approach [11] gives a different but rather compact expression for the tree level amplitude of gluons [13, 14]. It was proved [14] that this expression satisfies most of the requirements for the tree amplitude of gluons. In [22] it was argued that the string representation (a connected instanton) of the tree amplitude can indeed be decomposed into a summation of different MHV amplitudes (a set of disconnected instantons), giving precisely the CSW rules of perturbative calculations. Encouraged by the success of the googly amplitude calculation we will present some general discussions on the MHV diagrams in gauge theory. We note that in the calculation of the googly amplitudes by using the CSW rules, we only need the MHV vertices with 3 lines and the MHV vertices with 4 lines. So in a parity conserved theory the higher point (5 or more) MHV amplitudes can be obtained by parity transformation from the googly amplitudes and so the higher point MHV vertices can’t be chosen arbitrarily. We also prove that the CSW rules satisfy the dual ward identity and the charge conjugation identity [6].

The CSW proposal [3] can also be extended to gauge theory with fermions.
(see also [21]). Although the MHV (and googly) fermionic amplitudes can be easily obtained by supersymmetric Ward identities [30, 31, 6] we think it is still worthy to compute these amplitudes directly because the general non-MHV (googly) amplitudes cannot be determined in terms of amplitudes only and should be computed separately\(^1\). We will compute the googly amplitudes with fermions by extending the CSW rules with MHV vertices. For illustration we consider only the simplest case of a single quark-anti-quark pair. The general cases, including the supersymmetric case with gluinos, will be discussed in a separate publication [33]. Some generic non-MHV fermionic amplitudes were also computed in [21, 32].

Another interesting question is whether the CSW approach can be extended to theories with gravity. A naive extension of the the CSW rules to graviton doesn’t seem to work [24]. Nevertheless we believe that some similar rules for graviton must exist, given the simplicity of the MHV graviton amplitude [34] and the KLT relations between gauge theory and gravity [35]. In [26], Berkovits and Witten put forward a similar connection between the superconformal supergravity and closed string theory in twistor space. This may also suggest an extension of the CSW rules. In the last section we will present our partial successful and un-successful attempts to this problem. In particular we give a simple rule for the calculation of the off-shell amplitude with a single positive helicity graviton. This amplitude is proportional to the square of the (only) off-shell momentum and it is vanishing on shell.

This paper is organized as follows. In section 2, we present the computation of the generic googly amplitudes. In section 3, we give some general discussions on the MHV diagrams. We define precisely how the parity transformation operates in the CSW approach. We also prove the charge conjugation identity and the dual Ward identity in this section. In section 4, we extend the CSW rules to include fermions and compute the googly amplitude with a single quark and anti-quark pair. In the last section we make some investigations on the graviton MHV diagrams. Some technical proofs are relegated to two Appendices.

\(^1\)In an early version of this paper we don’t say this explicitly although we suspect this is the case. See the footnote of the recent paper [32]. We thank the referee to point out this to us.
The generic googly amplitudes in gauge theory

First let us recall the rules for calculating tree level gauge theory amplitudes as proposed in [3]. Here we follow the presentation given in [12] closely. We will use the convention that all momenta are outgoing. By MHV we always mean an amplitude with precisely two gluons of negative helicity. If the two gluons of negative helicity are labelled as \( r, s \) (which may be any integers from 1 to \( n \)), the MHV vertices (or amplitudes) are given as follows:

\[
V_n = \frac{\langle \lambda_r, \lambda_s \rangle^4}{\prod_{i=1}^{n} \langle \lambda_i, \lambda_{i+1} \rangle}.
\]

For an on shell (massless) gluon, the momentum in bispinor basis is given as:

\[
p_{a\dot{a}} = \sigma^{\mu}_{a\dot{a}} p_\mu = \lambda_a \bar{\lambda}_\dot{a}.
\]

For an off shell momentum, we can no longer define \( \lambda_a \) as above. The off-shell continuation given in [3] is to choose an arbitrary spinor \( \tilde{\eta}^{\dot{a}} \) and then to define \( \lambda_a \) as follows:

\[
\lambda_a = p_{a\dot{a}} \tilde{\eta}^{\dot{a}}.
\]

For an on shell momentum \( p \), we will use the notation \( \lambda_{pa} \) which is proportional to \( \lambda_a \):

\[
\lambda_{pa} \equiv p_{a\dot{a}} \tilde{\eta}^{\dot{a}} = \lambda_a \bar{\lambda}_\dot{a} \tilde{\eta}^{\dot{a}} \equiv \lambda_a \phi_p.
\]

As demonstrated in [3], it is consistent to use the same \( \tilde{\eta} \) for all the off shell lines (or momenta). The final result is independent of \( \tilde{\eta} \).

By using only MHV vertices, one can build a tree diagram by connecting MHV vertices with propagators. For the propagator of momentum \( p \), we assign a factor \( 1/p^2 \). Any possible diagram (involving only MHV vertices) will contribute to the amplitude. As proved in [3], a tree level amplitude with \( n_- \) external gluons of negative helicity must be obtained from an MHV tree diagram with \( n_- - 1 \) vertices. Another relation was given in [12],

\[
n_+ = \sum_i n_i (i - 3) + 1,
\]

when \( n_+ \) is the number of the external gluons with positive helicity, and \( n_i \) is the number of the vertices with exactly \( i \) lines. The other relation stated in the above is:

\[
n_- = \sum_i n_i + 1.
\]
From eq. (5) we can see that a tree level amplitude with \( n_+ \) external gluons of positive helicity will have no contribution from any diagram containing an MHV vertex with more than \( n_+ + 2 \) lines (not necessarily all internal). For the googly amplitude we have \( n_+ = 2 \). Any contributing diagram will have exactly one MHV vertex with 4 lines. The rest MHV vertices are all with 3 lines.

In order to compute the googly amplitude we will need the off shell amplitudes with \( n_+ = 1 \). These amplitudes are obtained in [12]. There are two cases. The first case is when the first particle with moment \( p_1 \) is off shell and has positive helicity. The amplitude is

\[
V_n(1+, 2-, \cdots, n-) = \frac{p_1^2}{\phi_2 \phi_n} \frac{1}{[2, 3][3, 4] \cdots [n-1, n]}.
\]  

(7)

The other case is when the off shell gluon has negative helicity. We relabel this gluon to be the first one and the amplitude is given as follows:

\[
V_n(1-, 2-, \cdots, r+, \cdots, n-) = \frac{\phi_4^4 p_1^2}{\phi_2 \phi_n} \frac{1}{[2, 3][3, 4] \cdots [n-1, n]}.
\]  

(8)

We stress the fact that the above off shell amplitudes are proportional to \( p_1^2 \) and they vanish when \( p_1 \) is also on shell (\( p_1^2 = 0 \)).

Now we compute the generic googly \( n \)-particle amplitude. The special case of which when the two positive helicity particles are adjacent was computed in [12]. The basic idea of the computation is the same. Now we label the two positive helicity particles to be 1 and \( r \). As mentioned in the previous section, it was also proved in [12] that for any googly amplitude the contributing diagram will have only one 4 line MHV vertex. By using this result, the amplitude is computed by using the diagram decomposition as shown in Fig. 4.

For any given \( r \), there are three kinds of diagrams as shown in Fig. 2, Fig. 3 and Fig. 4. They depend on whether the \( r \)-th gluon is in the second, third or the last blob.

All the 4 blob diagrams in these three kinds of diagrams can be computed by following the method used in [12]. By using the results in eqs. (7) and (8), the contribution corresponding to Fig. 2 is

\[
A_n^1 = \sum_{i=1}^{r-1} \sum_{j=r}^{n-2} \sum_{k=j+1}^{n-1} \sum_{l=k+1}^n \frac{\phi_4^4 p_1^2}{\phi_{l+1} \phi_i}.
\]
Figure 1: The diagram decomposition for the generic googly amplitude. We note that there is only one 4 gluon vertex.

\[
1 \times \frac{l + 1, l + 2 \cdots [n - 1, n][1, 2] \cdots [i - 1, i]}{p_{i+1}^2} \times \frac{1}{\phi_{i+1} \phi_j} \times \frac{1}{\Pi_{t=i+1}^{t+1} [t, t + 1]} \times \frac{1}{p_{t+1}^2} \times \frac{1}{\phi_{j+1} \phi_k} \times \frac{1}{\Pi_{t=j+1}^{t+1} [t, t + 1]} \times \frac{1}{p_{k+1,l}^2} \times \langle V_3, V_4 \rangle^3 \times \langle V_1, V_2, V_3, V_4 \rangle^3
\]

\[
= \frac{\phi_1^4 \phi_4^4}{\Pi_{t=1}^n [t, t + 1]} \sum_{i=1}^{n-1} \sum_{j=r}^{n-1} \sum_{k=j+1}^{n-1} \sum_{l=k+1}^{n} \frac{[i, i + 1]}{\phi_{i+1} \phi_{i+1}} \frac{[j, j + 1]}{\phi_{j+1} \phi_{j+1}}
\]

\[
\times \frac{[k, k + 1]}{\phi_k \phi_{k+1}} \frac{[l, l + 1]}{\phi_{l+1} \phi_{l+1}} \times \langle V_3, V_4 \rangle^3 \langle V_1, V_2, V_3, V_4 \rangle^3
\]

(9)
where\(^2\)

\[
V_1 = \sum_{s=i+1}^{n+i} \lambda_s \phi_s, \quad V_2 = \sum_{s=i+1}^{j} \lambda_s \phi_s, \quad (10)
\]

\[
V_3 = \sum_{s=j+1}^{k} \lambda_s \phi_s, \quad V_4 = \sum_{s=k+1}^{l} \lambda_s \phi_s, \quad (11)
\]

and when \(i \leq j\), we define \(p_{i,j}\) as \(p_{i,j} = \sum_{t=i}^{j} p_t\) as in \(\text{[3]}\), when \(i > j\), we define \(p_{i,j}\) as \(p_{i,j} = \sum_{t=i}^{n} p_t + \sum_{t=1}^{j} p_t\).

The contribution corresponding to Fig. 3 and Fig. 4 is similar. The result are

\[
A_n^2 = \prod_{t=1}^{r} \frac{\phi_i^4 \phi_r^4}{[t, t+1]} \sum_{i=1}^{r-2} \sum_{j=i+1}^{r-1} \sum_{k=r}^{n-1} \sum_{l=k+1}^{n} \frac{[i, i+1] [j, j+1]}{\phi_i \phi_{i+1} \phi_j \phi_{j+1}}
\]

\(^2\)Here and below the summation like \(\sum_{s=t+1}^{n+i}\) is understood as \(\sum_{s=t+1}^{n} + \sum_{s=1}^{i}\).
Figure 3: The diagram decomposition for the generic googly amplitude when $(j + 1) \leq r \leq k$.

\[
\begin{align*}
\frac{[k, k + 1][l, l + 1]}{\phi_k \phi_{k+1}} & \frac{\langle V_2, V_4 \rangle^4}{\langle V_1, V_2 \rangle \langle V_2, V_3 \rangle \langle V_3, V_4 \rangle \langle V_4, V_1 \rangle} \\
\end{align*}
\]  

(12)

and

\[
\begin{align*}
A_n^3 &= \frac{\phi_1^4 \phi_r^4}{\prod_{t=1}^n \langle t, t + 1 \rangle} \sum_{i=1}^{r-3} \sum_{j=i+1}^{r-2} \sum_{k=j+1}^{r-1} \sum_{l=r}^{n} [i, i+1] [j, j+1] \phi_i \phi_{i+1} \phi_j \phi_{j+1} \\
&\quad \times \frac{[k, k + 1][l, l + 1]}{\phi_k \phi_{k+1}} \frac{\langle V_2, V_4 \rangle^3}{\langle V_1, V_2 \rangle \langle V_3, V_4 \rangle \langle V_4, V_1 \rangle} \\
\end{align*}
\]

(13)

respectively.

The sum of $A_n^i$, $i = 1, 2, 3$ can be written as

\[
\begin{align*}
A_n &= \frac{\phi_1^4 \phi_r^4}{\prod_{t=1}^n \langle t, t + 1 \rangle} \sum_{i=1}^{r-1} \sum_{j=i+1}^{n} \sum_{k=j+1}^{l-1} \sum_{t=1}^{l-2} \sum_{u=1}^{l-1} [i, i+1] [j, j+1] \phi_i \phi_{i+1} \phi_j \phi_{j+1} \\
&\quad \times \frac{[k, k + 1][l, l + 1]}{\phi_k \phi_{k+1}} \frac{\langle V_1, V_2 \rangle \langle V_2, V_3 \rangle \langle V_3, V_4 \rangle \langle V_4, V_1 \rangle}{\langle V_1, V_2 \rangle \langle V_2, V_3 \rangle \langle V_3, V_4 \rangle \langle V_4, V_1 \rangle} \\
\end{align*}
\]

(14)
Figure 4: The diagram decomposition for the generic googly amplitude when \((k + 1) \leq r \leq l\).

where \(p\) and \(q\) in eq. (14) are the two indexes \((p = 2, 3, q = 3, 4, p \neq q)\) which satisfy that neither \(V_p\) nor \(V_q\) includes \(\lambda_r \phi_r\) as defined in eqs. (10) and (11).

As in [12], we can prove that the 4-fold summation in eq. (14) gives exactly the required result, i.e.

\[
\sum_{i=1}^{r-1} \sum_{l=\max(i+3,r)}^{n} \sum_{j=i+1}^{l-2} \sum_{k=j+1}^{l-1} \frac{[i, i + 1]}{\phi_i \phi_{i+1}} \frac{[j, j + 1]}{\phi_j \phi_{j+1}} \frac{[k, k + 1]}{\phi_k \phi_{k+1}} \frac{[l, l + 1]}{\phi_l \phi_{l+1}} \times \frac{\langle V_p, V_q \rangle^4}{\langle V_1, V_2 \rangle \langle V_2, V_3 \rangle \langle V_3, V_4 \rangle \langle V_4, V_1 \rangle} = \frac{[1, r]^4}{\phi_1^4 \phi_r^4}. \tag{15}
\]

The proof of this identity, eq. (15), will be given in Appendix A. As in [12], it is proved by analyzing its pole terms and finding that all the pole terms are vanishing.

By using eq. (15) in eq. (14), we have

\[
A_n(1+, 2-, \cdots, r+, \cdots, n-) = \frac{[1, r]^4}{\Pi_{i=1}^{n}[i, i + 1]} \tag{16}
\]
This is the known result for the googly amplitude [4, 5]. It is the complex conjugate of the MHV amplitude, eq. (1), for Minkowski signature.

3 Some general discussions on the MHV diagrams in gauge theory

3.1 Parity transformation and the googly amplitude

As shown in the previous section, in our calculation of the googly amplitudes, we use the 3-line and 4-line MHV vertices only. The vertices with more than 4 lines don’t appear in the contributing diagrams. A parity transformation will exchange the googly amplitudes with the MHV amplitudes. So in a parity invariant theory, once the off-shell continuation of 3 point and 4 point MHV amplitudes are given, the on-shell \( n \) point MHV amplitudes (\( n > 4 \)) can be obtained from the googly amplitudes by parity transformation. The higher MHV amplitudes (and vertices) can’t be chosen arbitrarily.

The parity invariance of the tree level amplitude is discussed in [14, 18] using string theory in twistor space [1]. Other related works are [16, 15, 17, 19].

We can make the parity transformation more precise. Denoting the parity transformation in Minkowski space by \( \mathcal{P} \), we can choose its action on the momentum as follows:

\[
\lambda_1(\mathcal{P}p) = -\tilde{\lambda}_2(p), \quad \lambda_2(\mathcal{P}p) = \tilde{\lambda}_1(p). \tag{17}
\]

This transformation satisfies our basic requirement of changing a quantity to its complex conjugate:

\[
\langle \lambda(\mathcal{P}p_1), \lambda(\mathcal{P}p_2) \rangle = [\tilde{\lambda}(p_1), \tilde{\lambda}(p_2)]. \tag{18}
\]

For the polarization vectors, we have

\[
\epsilon_+^{aa} = \frac{\mu_a \tilde{\lambda}_a}{\langle \mu, \lambda \rangle}, \quad \epsilon_-^{aa} = \frac{\lambda_a \tilde{\mu}_a}{[\lambda, \tilde{\mu}]} \tag{19}
\]

If we choose \( \mu_1(\mathcal{P}p) = -\tilde{\mu}_2(p) \) and \( \mu_2(\mathcal{P}p) = \tilde{\mu}_1(p) \), then we have \( \epsilon^\mu(\mathcal{P}p, h) = P_\mu^\nu \epsilon^\nu(p, -h) \) (\( h \) is the helicity). From this we get

\[
A(\mathcal{P}p_1, h_1; \ldots; \mathcal{P}p_n, h_n) = A(p_1, -h_1; \cdots; p_n, -h_n). \tag{20}
\]
So we have

\[
A(p_1, +; \cdots, p_r, -; \cdots, p_s, -; \cdots, p_n, +) = A(\mathcal{P} p_1, -; \cdots, \mathcal{P} p_r, +; \cdots, \mathcal{P} p_s, +, \cdots, \mathcal{P} p_n, -) = \prod_{i=1}^{n} \frac{[\bar{\lambda}(\mathcal{P} p_i), \lambda(\mathcal{P} p_{i+1})] \langle \lambda(p_r), \lambda(p_s) \rangle^4}{\Pi_{i=1}^{n} \langle \lambda(p_i), \lambda(p_{i+1}) \rangle}.
\]

This shows that a parity transformation indeed exchange the goooly amplitudes with the MHV amplitudes, as we expected.

### 3.2 The charge conjugation

![Diagram with labels](image)

Figure 5: The diagram decomposition for the gauge amplitude \(A(1, \cdots, n)\).

Charge conjugation can be easily implemented in the CSW approach. In gauge theory, charge conjugate invariance gives the following identity for the
We note that the off shell MHV vertices also satisfies this identity. Because all the tree level amplitudes are computed from the MHV vertices in the framework of CSW, we could easily prove the above identity by doing charge conjugation operation on the "Feynman diagrams". We note that Eq. (22) has also been proved in [14] for the case when all particles are on-shell using the connected instanton in twistor string theory [1].

We will prove eq. (22) by mathematical induction. The case for \( n = 3 \) can be easily proven case by case. Assuming that eq. (22) is true for all \( k < n \) for both on-shell amplitudes and off-shell amplitudes, we will prove that it is also true for \( k = n \).

The case when the amplitude \( A_n(p_1, h_1; p_2, h_2; \cdots; p_n, h_n) \) has less than 2
gluons with negative helicity are trivial. Since

\[ A_n(p_1, h_1; p_2, h_2; \cdots; p_n, h_n) = 0 = (-1)^n A_n(p_n, h_n; \cdots; p_2, h_2; p_1, h_1). \]  

(23)

When the amplitude \( A_n(p_1, h_1; p_2, h_2; \cdots; p_n, h_n) \) is an MHV amplitude, the amplitude \( A_n(p_n, h_n; \cdots; p_2, h_2; p_1, h_1) \) is an MHV amplitude, too. In this case we can easily prove eq. (22) by using eq. (1).

If the amplitude \( A_n(p_1, h_1; p_2, h_2; \cdots; p_n, h_n) \) has more than 2 gluons with negative helicity, then the MHV diagrams has more than 1 MHV vertices [3]. We can use the diagram decomposition as in Fig. 5 to calculate this amplitude.³ The helicities \( h_{q_1}, \cdots, h_{q_k} \) of the momenta \( q_1, \cdots, q_k \) must satisfy the constraint that the vertex \( V_{k+1}(p_1, h_1; q_1, h_{q_1}; \cdots; q_k, h_{q_k}) \) is an MHV vertex. For every diagram in this diagram decomposition, there is a unique corresponding diagram in the diagram decomposition used for calculating \( A_n(p_n, h_n; \cdots; p_2, h_2; p_1, h_1) \) as in Fig. 3 with the same \( h_{q_1}, \cdots, h_{q_k} \). In fact this is a one-to-one correspondence between the diagrams in these two diagram decompositions.

By using the above diagram composition we have

\[
A_n(p_1, h_1; p_2, h_2; \cdots; p_n, h_n) = \sum V_{k+1}(p_1, h_1; q_1, h_{q_1}; \cdots; q_k, h_{q_k}) \times \frac{1}{q_1} \times \cdots \times \frac{1}{q_k} \\
\times A_{n+1}(p_2, h_2; \cdots; p_{n+1}, h_{n+1}; -q_1, -h_{q_1}) \\
\times \cdots \times A_{n+k+1}(p_{n-k+1}, h_{n-k+1}; \cdots; p_n, h_n; -q_k, -h_{q_k}),
\]  

(24)

where

\[ q_i = \sum_{j=n_1+n_2+\cdots+n_{i-1}+1}^{n_1+n_2+\cdots+n_{i+1}} p_j, \]  

(25)

for \( 1 \leq i \leq k \) and the summation in eq. (24) is over \( n_1, \cdots, n_k \) subject to the constrains \( n_1 + \cdots + n_k = n - 1, n_i > 0 \). There is also a summation over all possible helicity \( h_{q_1}, \cdots, h_{q_k} \) subject to the constraint that the vertex \( V_{k+1}(p_1, h_1; q_1, h_{q_1}; \cdots; q_k, h_{q_k}) \) is an MHV vertex. In the above, the momentum \( p_1 \) can be off shell.

From the assumed result for all less multi-gluon amplitudes, we have

\[
A_n(p_1, h_1; p_2, h_2; \cdots; p_n, h_n) = \sum (-1)^{k+1} V_{k+1}(p_1, h_1; q_k, h_{q_k}; \cdots; q_1, h_{q_1})
\]  

³We note that when \( n_+ = 0 \), there are no contributing diagrams and the amplitude vanishes. Then it is trivial to find that eq. (22) is valid in this case.
\[ \times \frac{1}{q_1^n} \times \cdots \times \frac{1}{q_{k_1}^j} \times (-1)^{n_1+1} A_{n_1+1}(p_{n_1+1}, h_{n_1+1}; p_2, h_2; -q_1, -h_1) \]
\[ \times \cdots \times (-1)^{n_{k_1}+1} A_{n_{k_1}+1}(p_{n_{k_1}+1}, \cdots p_{n_{k_1}+n_{k_1}-1}, h_{n_{k_1}+1}; -q_k, -h_k) \]
\[ = \sum V_{k+1}(p_1, h_1; q_k, h_{q_k}; \cdots, q_1, h_{q_1}) \frac{1}{q_2^n} \times \cdots \]
\[ \times \frac{1}{q_{k_2}^j} A_{n_{k_1}+1}(p_{n_{k_1}+1}, h_{n_{k_1}+1}; p_2, h_2; -q_1, -h_1) \times \cdots \]
\[ \times A_{n_{k_1}+1}(p_{n_{k_1}+1}, h_{n_{k_1}+1}; \cdots p_{n_{k_1}+n_{k_1}-1}, h_{n_{k_1}+1}; -q_k, -h_k) \]
\[ \times (-1)^{k+1+n_2+n_3+\cdots+n_{k_1}+k} \]
\[ = (-1)^n A_n(p_n, h_n; \cdots p_2, h_2; p_1, h_1). \] (26)

The degenerate case when some \( n_i \)’s equal to 1 is also correctly included in the previous equation. This completes our proof of eq. (22).

### 3.3 The dual Ward identity

The dual Ward identity is [5]

\[ \sum_{\sigma \in \mathbb{Z}_{n-1}} A(\sigma(1), \cdots, \sigma(n-1), n) = 0. \] (27)

where the summation \( \sigma \) is over all of the cyclic permutation of \( 1, \cdots, n-1 \) and the position of \( n \) is held fixed to be the last one by using the cyclic symmetry of the amplitude. This identity reflect the decoupling of the \( U(1) \) degree of freedom and links the factorization of the partial amplitudes to the factorization of the full amplitudes [3]. This has been discussed in [14]. It is also proved in [35] that the dual Ward identity is valid for (on-shell) MHV amplitudes. We will show that the above dual Ward identity is valid for all tree-level amplitudes in the framework of CSW.

Firstly, we prove that the dual Ward identity is true for the off shell MHV vertices. By assuming that the two gluons with negative helicity are \( g_p \) and \( g_q \), we must prove the following:

\[ \sum_{\sigma \in \mathbb{Z}_{n-1}} V(\sigma(1), \cdots, \sigma(n-1), n) \]
\[ = \langle p, q \rangle^4 \sum_{\sigma \in \mathbb{Z}_{n-1}} \frac{1}{\langle \sigma(1), \sigma(2) \rangle \cdots \langle \sigma(n-1), n \rangle \langle n, \sigma(1) \rangle} = 0. \] (28)
In order to prove this last equality, we note first the following relation:

\[
\langle i, j \rangle = \lambda_{i1} \lambda_{j2} - \lambda_{i2} \lambda_{j1} = \left( \frac{\lambda_{i1}}{\lambda_{i2}} - \frac{\lambda_{j1}}{\lambda_{j2}} \right) \lambda_{i2} \lambda_{j2}.
\]  

(29)

Setting \( \psi_i = \lambda_{i1}/\lambda_{i2} \), we have

\[
\sum_{\sigma \in \mathbb{Z}_{n-1}} \frac{1}{(\sigma(1), \sigma(2)) \cdots (\sigma(n-1), n) (n, \sigma(1))} = \frac{1}{(\prod_{i=1}^{n} \lambda_{i2})^2}
\]

\[
\times \sum_{\sigma \in \mathbb{Z}_{n-1}} \frac{1}{(\psi_{\sigma(1)} - \psi_{\sigma(2)}) \cdots (\psi_{\sigma(n-1)} - \psi_n)(\psi_n - \psi_{\sigma(1)})}.
\]  

(30)

So what we need to prove is the following identity:

\[
\sum_{\sigma \in \mathbb{Z}_{n-1}} \frac{1}{(\psi_{\sigma(1)} - \psi_{\sigma(2)}) \cdots (\psi_{\sigma(n-1)} - \psi_n)(\psi_n - \psi_{\sigma(1)})} = 0,
\]  

(31)

for arbitrary \( \psi_i \)'s.

We will prove eq. (31) by mathematical induction. The case for \( n = 3 \) can be easily checked to be valid. Assuming that it is valid for \( k = n - 1 \), we will show that it is valid for \( k = n \).

We will first prove that the l.h.s. is a constant by showing that all the pole terms are vanishing. When \( \psi_i \to \infty \) (\( 1 \leq i \leq n + 1 \)), it is evident that the pole terms are vanishing. So we only need to consider the finite pole terms. The possible finite pole terms appear when \( \psi_j = \psi_n, 1 \leq j \leq n - 1 \), or \( \psi_i = \psi_{i+1}, 1 \leq i \leq n - 2 \), or \( \psi_{n-1} = \psi_1 \).

When \( \psi_j = \psi_n, 1 \leq j \leq n - 1 \), the pole terms in eq. (31) are from the following two cyclic permutations:

\[
\sigma_{j-1}(1, \ldots, n-1) = (j, j+1, \ldots, n-1, 1, 2, \ldots, j-2, j-1),
\]  

(32)

and

\[
\sigma_j(1, \ldots, n-1) = (j+1, j+2, \ldots, n-1, 1, 2, \ldots, j-1, j).
\]  

(33)

These give 2 pole terms:

\[
\frac{1}{\psi_j - \psi_{j+1}} \frac{1}{\psi_{j+1} - \psi_{j+2}} \cdots \frac{1}{\psi_{j-1} - \psi_n} \frac{1}{\psi_n - \psi_j} + \frac{1}{\psi_n - \psi_{j+1}} \frac{1}{\psi_{j+1} - \psi_{j+2}} \cdots \frac{1}{\psi_{j-1} - \psi_j} \frac{1}{\psi_j - \psi_n} = \frac{1}{\psi_n - \psi_j} \left[ \frac{1}{\psi_j - \psi_{j+1}} \frac{1}{\psi_{j+1} - \psi_{j+2}} \cdots \frac{1}{\psi_{j-1} - \psi_n} - (\psi_n \leftrightarrow \psi_j) \right].
\]  

(34)
The residues in the bracket vanish by taking $\psi_j = \psi_n$.

For $\psi_i = \psi_{i+1}$, $1 \leq i \leq n-2$, the only cyclic permutation which doesn’t give a pole term is:

$$\sigma_i(1, 2, \ldots, n-1) = (i + 1, i + 2, \ldots, n - 1, 1, 2, \ldots, i - 1, i).$$

(35)

The residues are

$$\sum_{\sigma \neq \sigma_i} \frac{1}{\psi_{\sigma(1)} - \psi_{\sigma(2)}} \frac{1}{\psi_{\sigma(2)} - \psi_{\sigma(3)}} \cdots \frac{1}{\psi_{\sigma(n-1)} - \psi_n} \frac{1}{\psi_n - \psi_{\sigma(1)}}. \quad (36)$$

One easily convinces oneself that the above summation is actually the l.h.s of eq. (31) with the deletion of $\psi_i$ and so it sums to zero by the assumption of our mathematical induction. This proves that the residues for $\psi_i = \psi_{i+1}$ vanish. The case for $\psi_{n-1} = \psi_1$ can be proved by the same method.

So we proved that all the finite pole terms are vanishing and we conclude that the l.h.s. must be a constant. This constant can only be zero because it is homogeneous (with negative degree) in $\psi_i$’s. This completes our proof of eq. (31).

By using the above result for dual Ward identity for the off-shell MHV vertices, one can easily prove the general dual Ward identity, eq. (27). The strategy is to write each amplitude $A(\sigma(1), \ldots, \sigma(n-1), n)$ as a sum over all possible MHV vertices connected with the $n$-th gluon as shown in Fig. 7. For a fixed MHV vertex, the summation over all possible cyclic permutations are decomposed as a sum over cyclic permutations of $q_1, q_2, \ldots, q_m$.

4 Each sum over cyclic permutations of $q_1, q_2, \ldots, q_m$ is zero by using the dual Ward identity for MHV vertex and the general dual Ward identity then follows.

## 4 The googly amplitudes with fermions

The proposal of [3] can also be extended to gauge theory with fermions (see also [21]). Although the MHV (and googly) fermionic amplitudes can be easily obtained by supersymmetric Ward identities [30, 31, 6] we think it is

4This statement should be proved rigorously. We will not try to spell out the full details of the proof here.
still worthy to compute these amplitudes directly because the general non-MHV (googly) ammplitudes cannot be determined in terms of amplitudes only and should be computed separately. In this section we will compute the googly amplitudes with fermions by extending the CSW rules with MHV vertices. We will consider only the simplest case of a single quark-anti-quark pair. The general cases, including the supersymmetric case with gluinos, will be discussed in a separate publication [33]. We also note that some generic non-MHV fermionic amplitudes were also computed in [21, 32].

For the case of a single quark-anti-quark pair, the MHV vertices are as follows (only the $I$-th gluon has negative helicity):

$$A(\Lambda^+_q, g^+_1, \cdots, g^+_I, \cdots, g^+_n, \Lambda^-_{\bar{q}}) = -\frac{\langle q, I \rangle \langle \bar{q}, I \rangle^3}{\langle q_1 \rangle \langle 1, 2 \rangle \cdots \langle n, \bar{q} \rangle \langle \bar{q}, q \rangle} , \quad (37)$$

$$A(\Lambda^-_\bar{q}, g^+_1, \cdots, g^+_I, \cdots, g^+_n, \Lambda^+_q) = \frac{\langle q, I \rangle^3 \langle \bar{q}, I \rangle}{\langle q_1 \rangle \langle 1, 2 \rangle \cdots \langle n, \bar{q} \rangle \langle \bar{q}, q \rangle} , \quad (38)$$

by denoting the quark with helicity $\pm$ as $\Lambda^\pm_q$ and the anti-quark as $\Lambda^\pm_{\bar{q}}$. Gluons are denoted as $g_i^\pm$ in an obvious notation. What we want to do is to
reproduce the following googly amplitudes (only the $I$-th gluon has positive helicity):

\[
A(\Lambda^+_q, g_1^- \cdots g_i^+ \cdots g_n^-, \Lambda^-_\bar{q}) = \frac{[q, I]^3[q, I]}{[q_1][1, 2] \cdots [n, \bar{q}][q, \bar{q}]}, \tag{39}
\]

\[
A(\Lambda^-_q, g_1^- \cdots g_i^+ \cdots g_n^-, \Lambda^+_\bar{q}) = -\frac{[q, I][q, I]^3}{[q_1][1, 2] \cdots [n, \bar{q}][q, \bar{q}]). \tag{40}
\]

We use the same off shell continuation as given in [3] (see also section 2) for off-shell momenta lines. The propagator for both gluon and gluino internal lines is just $1/p^2$, as explained in [21].

We first calculate the amplitudes with a quark-anti-quark pair when all gluons have negative helicity and only one particle is off-shell. By using the same method as in [12], we find that all vertices in the contribution diagrams are 3-line MHV vertices. When all the 3 particles are off shell, the MHV amplitudes with a quark-anti-quark pair can be written as:

\[
A(\Lambda^+_q, g_1^- \cdots g_i^+ \cdots g_n^-, \Lambda^-_\bar{q}) = \frac{(1, \bar{q})^2}{\langle q, 1 \rangle} = \langle q, \bar{q} \rangle = \langle q, 1 \rangle = \langle 1, \bar{q} \rangle, \tag{41}
\]

\[
A(\Lambda^-_q, g_1^- \cdots g_i^+ \cdots g_n^-, \Lambda^+_\bar{q}) = -\frac{(1, \bar{q})^2}{\langle q, 1 \rangle} = -\langle q, \bar{q} \rangle = -\langle 1, \bar{q} \rangle = -\langle q, 1 \rangle. \tag{42}
\]

The amplitudes $A(\Lambda^+_q, g_1^- \cdots g_n^-, \Lambda^-_\bar{q})$ when $\Lambda^+_q$ is off shell are given as follows:

\[
A(\Lambda^+_q, g_1^- \cdots g_n^-, \Lambda^-_\bar{q}) = \frac{p^2}{\phi_1 [1, 2][2, 3] \cdots [n - 1, n][n, \bar{q}]}, \tag{43}
\]

\[
A(\Lambda^-_q, g_1^- \cdots g_n^-, \Lambda^+_\bar{q}) = -\frac{p^2}{\phi_1 [1, 2][2, 3] \cdots [n - 1, n][n, \bar{q}]}, \tag{44}
\]

and

\[
A(\Lambda^+_q, g_1^- \cdots g_n^-, \Lambda^-_\bar{q}) = \frac{p^2 \phi^2_q}{\phi_n [q, 1][1, 2][2, 3] \cdots [n - 1, n]}, \tag{45}
\]

\[
A(\Lambda^-_q, g_1^- \cdots g_n^-, \Lambda^+_\bar{q}) = -\frac{p^2 \phi^2_q}{\phi_n [q, 1][1, 2][2, 3] \cdots [n - 1, n]}, \tag{46}
\]

when the anti-quark $\Lambda^+_q$ is off-shell. We will not give the proof of the above formulas here.

18
When the off shell particle is $g_i$, the result is

\[ A(\Lambda_q^+, g_i^-, \cdots, g_n^-, \Lambda_{\bar{q}}^-) = \frac{p_i^2 \phi_i^3 \phi_{\bar{q}}}{\phi_{i-1} \phi_{i+1}} \times \frac{1}{[q, 1][1, 2]\cdots[i - 2, i - 1][i + 1, i + 2]\cdots[n, \bar{q}][\bar{q}, q]}, \]  

(47)

\[ A(\Lambda_q^-, g_i^-, \cdots, g_n^-, \Lambda_{\bar{q}}^+) = -\frac{p_i^2 \phi_i^3 \phi_{\bar{q}}}{\phi_{i-1} \phi_{i+1}} \times \frac{1}{[q, 1][1, 2]\cdots[i - 2, i - 1][i + 1, i + 2]\cdots[n, \bar{q}][\bar{q}, q]}, \]  

(48)

Here and in the remaining part of this section the index 0 refers to $\Lambda_q$ and the index $n+1$ refers to $\Lambda_{\bar{q}}$.

\[ \begin{align*} 
&I \\
&i + 1 \\
&j \\
&j + 1 \\
&k \\
&i \\
&k + 1 \\
&\Lambda_q \\
&\Lambda_{\bar{q}} 
\end{align*} \]

Figure 8: A sample diagram of 4-line MHV vertex with the quark-anti-quark pair.

Now we begin to compute the googly amplitudes with one quark-anti-quark pair. Using the same method used in [12], one can find that in every contributing diagram there is only one vertex with 4 lines, all other vertices are with 3 lines. For the amplitude $A(\Lambda_q^+, g_i^+, \cdots, g_j^+, \cdots, g_n^-, \Lambda_{\bar{q}}^-)$, one
sample diagram was shown in Fig. 8. By using the known results for the amplitudes with exactly one off shell particle given previously in eqs. (43)-(48), this gives:

\[
\frac{\phi_2^2 \phi_I^4}{[q, 1][1, 2] \cdots [n-1, n][n, q]} \sum_{i=0}^{l-1} \sum_{k=1}^{n-1} \sum_{j=1}^{n} \frac{[i, i + 1]}{[j, j + 1]} \phi_i \phi_{i+1} \phi_j \phi_{j+1} \\
\times \frac{[k, k + 1]}{\phi_k \phi_{k+1}} \frac{-\langle V_1, V_3 \rangle \langle V_4, V_3 \rangle^3}{\langle V_1, V_2 \rangle \langle V_2, V_3 \rangle \langle V_3, V_4 \rangle \langle V_4, V_1 \rangle},
\]

(49)

where

\[
V_1 = \sum_{s=0}^{i} \lambda_s \phi_s, \quad V_2 = \sum_{s=i+1}^{j} \lambda_s \phi_s,
\]

\[
V_3 = \sum_{s=j+1}^{k} \lambda_s \phi_s, \quad V_4 = \sum_{s=k+1}^{n+1} \lambda_s \phi_s.
\]

(50)

(51)

The complete result is

\[
A = \frac{\phi_2^2 \phi_I^4}{[q, 1][1, 2] \cdots [n-1, n][n, q]} \sum_{i=0}^{l-1} \sum_{k=\max\{l, i+2\}}^{n} \sum_{j=i+1}^{k} \frac{[i, i + 1]}{[j, j + 1]} \phi_i \phi_{i+1} \\
\times \frac{[j, j + 1]}{\phi_j \phi_{j+1}} \frac{[k, k + 1]}{\phi_k \phi_{k+1}} \frac{-\langle V_1, V_3 \rangle \langle V_4, V_3 \rangle^3}{\langle V_1, V_2 \rangle \langle V_2, V_3 \rangle \langle V_3, V_4 \rangle \langle V_4, V_1 \rangle} \\
+ \frac{\phi_3^2 \phi_I^4}{[q, 1][1, 2] \cdots [n-1, n][n, q][\bar{q}, \bar{q}]} \sum_{i=0}^{l-1} \sum_{k=\max\{l, i+3\}}^{n} \sum_{j=i+1}^{k} \frac{[i, i + 1]}{[l, l + 1]} \phi_i \phi_{i+1} \\
\times \frac{[j, j + 1]}{\phi_j \phi_{j+1}} \frac{[k, k + 1]}{\phi_k \phi_{k+1}} \frac{\langle \bar{V}_r, \bar{V}_s \rangle^2}{\langle \bar{V}_1, \bar{V}_2 \rangle \langle \bar{V}_2, \bar{V}_3 \rangle \langle \bar{V}_3, \bar{V}_4 \rangle \langle \bar{V}_4, \bar{V}_1 \rangle}.
\]

(52)

where

\[
\bar{V}_1 = \sum_{s=0}^{i} \lambda_s \phi_s + \sum_{s=l+1}^{n+1} \lambda_s \phi_s, \quad \bar{V}_2 = \sum_{s=i+1}^{j} \lambda_s \phi_s,
\]

\[
\bar{V}_3 = \sum_{s=j+1}^{k} \lambda_s \phi_s, \quad \bar{V}_4 = \sum_{s=k+1}^{l} \lambda_s \phi_s.
\]

(53)

(54)

The \( p \) in eq. (52) is the index \( (p = 2, 3) \) which satisfies that \( V_p \) doesn’t include \( \lambda_f \phi_I \) as defined in eqs. (50) and (51) and the \( r \) and \( s \) in eq. (52) are
the two indices \( r = 2, 3, s = 3, 4, r \neq s \) which satisfy that neither \( \tilde{V}_r \) nor \( \tilde{V}_s \) includes \( \lambda_I \phi_I \) as defined in eqs. (53) and (54). The summations in eq. (52) can be done by using identities involving \( \lambda_i \) as in the gluon googly amplitude. After doing this summation we obtained the correct googly amplitude with a single quark-anti-quark pair as given in eqs. (39) and (40). The details for the relevant identities and also the extension to multi-pairs of quark-anti-quark pairs and gluinos will be given in a separate publication [33].

5 The MHV diagrams for gravity

Encouraged by the success of the CSW approach to gauge theory, it is natural to ask if a similar approach to gravity exists. We expected so also because there exist some close relations between the gravity amplitudes and the gauge amplitudes, the famous KLT relations [35].

We use the same off-shell continuation \( \lambda_a = p_a \tilde{\eta}^a \) as in [3]. The off shell MHV vertex with 3 gravitons is [34]

\[
V_{3}^{graviton}(1+, 2-, 3-) = \left( \frac{\langle 2, 3 \rangle^3}{\langle 1, 2 \rangle \langle 3, 1 \rangle} \right)^2,
\]

and the propagator for the graviton with momentum \( p \) is still \( 1/p^2 \).

As in gauge theory, we first compute \( A(1+, 2-, \cdots, n-) \) when only one particle is off-shell. We will give a formula for \( A(1+, 2-, \cdots, n-) \) when only the momentum \( p_i \) is off-shell. This amplitude vanishes when all momenta are on shell. So we expect that it is proportional to \( p_i^2 \). This turns out to be true for gravity. We note that the vanishing for the 4-particle and 5-particle on-shell amplitudes were also obtained in [24].

The diagrams which contribute to \( A(1+, 2-, \cdots, n-) \) include the MHV vertices with 3 lines only. By using momentum conservation, one can show that the MHV vertex \( V_3(1+, 2-, 3-) \) is actually polynomial in \( \lambda \):

\[
V_3(1+, 2-, 3-) = \langle \lambda_1, \lambda_2 \rangle^2 = \langle \lambda_2, \lambda_3 \rangle^2 = \langle \lambda_3, \lambda_1 \rangle^2.
\]

In order to present the rules for the computation of \( A(1+, 2-, \cdots, n-) \), we will need some basic concepts and notations from graph theory. By a graph \( \Gamma \), we mean two set: the vertex set \( V \) and the edge set \( E \subseteq \{ e_{ij} | i, j \in V, i \neq j \} \).

We will use the undirected graph only. This means that \( e_{ij} = e_{ji} \) for all \( i, j \in V \). We will denote the vertex set of graph \( \Gamma \) as \( V(\Gamma) \) and denote the
edge set of graph $\Gamma$ as $E(\Gamma)$. A connected graph not containing any cycles is called a tree. Two vertex $i,j$ are adjacent if there is a edge $e_{ij}$ in $E(\Gamma)$.

We relabel the off-shell graviton to be the first one. The formula for the amplitudes is:

$$A(p_1, h_1; p_2, h_2; \cdots; p_n, h_n) = p_1^2 \sum_{\Gamma, V(\Gamma) = S(n)} P(\Gamma),$$

(57)

where $h_i = \pm 2$ is the helicity of the graviton whose momentum is $p_i$ and $\Gamma$ is undirected tree whose vertex set is $V(\Gamma) = S(n) \equiv \{2, 3, \cdots, n\}$ and $P(\Gamma)$ can be obtained from the following rules:

- For every vertex $i$ in $V(\Gamma)$, there is a factor $p(i) = \phi_i^{2h_i}$. It means that if the graviton with momentum $p_i$ has positive helicity, the factor is $\phi_i^4$; otherwise the factor is $\phi_i^{-4}$. We stress the fact that there is only one positive helicity graviton.

- For every edge $e_{ij}$ in $E(\Gamma)$ there is a factor $p(e_{ij})$:

$$p(e_{ij}) = \phi_i^2 \phi_j^2 \langle i, j \rangle [i, j].$$

(58)

$P(\Gamma)$ is the product of above factors:

$$P(\Gamma) = \prod_{i \in V(\Gamma)} p(i) \prod_{e_{ij} \in E(\Gamma)} p(e_{ij}).$$

(59)

By using the above rules we have

$$A(p_1, h_1, \cdots, p_n, h_n) = p_1^2 \prod_{i=2}^n \phi_i^{2h_i} \sum_{\Gamma, V(\Gamma) = S(n)} \prod_{e_{ij} \in E(\Gamma)} p(e_{ij}).$$

(60)

The summation in eq. (60) is over all of the inequivalent undirected trees with vertex set $S_n$. The result can be proved by mathematical induction. The detail is relegated to Appendix B.

The on-shell 4-graviton MHV amplitude is [33]:

$$A_4(1+, 2+, 3-, 4-) = \frac{\langle 3, 4 \rangle^8}{\langle 1, 2 \rangle \langle 1, 3 \rangle \langle 1, 4 \rangle \langle 2, 3 \rangle \langle 2, 4 \rangle \langle 3, 4 \rangle \langle 1, 2 \rangle}.$$  

(61)

We note that a straightforward off-shell continuation $\lambda_a = p_a \tilde{q}^a$ is not possible for $A_4$ because of the existence of the “anti-holomorphic term” [3, 4]. By
using the on-shell condition, like $p^2 = p^2_1 = 0$, and momentum conservation, one can write this term in various forms which are equivalent on shell and include the "holomorphic terms" and the momenta product only.

For example, we can use $\langle 3, 4 \rangle [3, 4] = 2p_3 \cdot p_4$ to write $[3, 4]$ as $2p_3 \cdot p_4 / \langle 3, 4 \rangle$. On the other hand, using the on-shell condition $p^2_i = 0, i = 1, \cdots, 4$ and the momentum conservation, we have $2p_3 \cdot p_4 = p^2_{34} = 2p_1 \cdot p_2$. We can use these relations to give two more way of writing the "non-holomorphic" expression $[3, 4]$.

We can also use $\langle 1, 2 \rangle [2, 3] + \langle 1, 4 \rangle [4, 3] = 0$ to write $[3, 4]$ as $\langle 1, 2 \rangle [2, 3] = \langle 1, 4 \rangle [4, 3] = \langle 1 \rangle \langle 3 \rangle \langle 2 \rangle \langle 4 \rangle$.

or use $\langle 1, 3 \rangle [3, 4] + \langle 1, 2 \rangle [2, 4] = 0$ to write $\langle 3, 4 \rangle = \langle 1, 2 \rangle = \langle 1 \rangle \langle 3 \rangle \langle 2 \rangle \langle 4 \rangle$. (62)

One can try to write all the possible (on shell) equivalent forms for the 4-graviton MHV amplitude. There are about 9 different forms which satisfy the obvious symmetry. Nevertheless we have not been able to obtain the correct 5-graviton amplitude by using any one of these forms or one of their linear combination. It is safe to conclude that a naive extension of the CSW approach to gravity failed (see also [24]). New ingredient must be introduced in order to develop a CSW like rules for gravity. The similar connection between conformal supergravity and twistor string theory discussed in the recent paper [26] may offer some clues.

To extend the CSW approach further, we may change the 3-particle vertex. A possible “MHV vertex” for charged particle is

$$A(1+, 2-, 3-) = \left( \frac{\langle 2, 3 \rangle^3}{\langle 1, 2 \rangle \langle 3, 1 \rangle} \right)^{2s-1} = \langle 1, 2 \rangle^{2s-1} = 3, 3 = 3, 1 = 3, 1$$

where $s$ is a positive integer. By using this vertex and the CSW rules, one can also compute $A(1+, 2-, 3-, 4-)$ and the result is

$$A(1+, 2-, 3-, 4-) = (\phi_2 \phi_3 \phi_4)^{-(2s-1)} \times \left( \frac{\langle 2, 3 \rangle^{2s-2}}{\langle 2, 3 \rangle} \right) \langle \lambda_{23}, \lambda_{p4} \rangle^{2s-1}$$

$$+ \left( \phi_3 \phi_4 \phi_2 \phi_3 \phi_4 \right)^{-(2s-1)} \times \left( \frac{\langle 2, 3 \rangle^{2s-2}}{\langle 2, 3 \rangle} \right) \langle \lambda_{23}, \lambda_{p4} \rangle^{2s-1}. \quad (65)$$
By using the following equation:

$$\frac{\langle \lambda_{23}, \lambda_{p4} \rangle}{[2, 3]} + \frac{\langle \lambda_{p2}, \lambda_{34} \rangle}{[3, 4]} = 0,$$  \hspace{1cm} (66)

we have

$$A(1+, 2-, 3-, 4-) = \frac{1}{[2, 3]^{2s-1}} \left[ (p_2 \cdot p_3)^{2s-2} - (p_3 \cdot p_4)^{2s-2} \right]$$

$$\times \langle \lambda_{23}, \lambda_{p4} \rangle^{2s-1} (\phi_2 \phi_3 \phi_4)^{-(2s-1)}. \hspace{1cm} (67)$$

So when $s > 1$ this amplitudes doesn’t vanish for generic $\lambda_i, \tilde{\lambda}_i (1 \leq i \leq 4)$. This indicates that the CSW approach can’t be arbitrarily extended to include higher derivative theories. It remains to discover the hidden principle behind the success of the CSW approach to gauge theory and its coupling to fermions, at least for tree level calculations.

### Acknowledgments

We would like to thank Zhe Chang, Bin Chen, Han-Ying Guo, Miao Li, Jian-Xin Lu, Jian-Ping Ma, Ke Wu and Yong-Shi Wu for discussions. Jun-Bao Wu would like to thank Qiang Li for help on drawing the figures. Chuan-Jie Zhu would like to thank Jian-Xin Lu and the hospitality at the Interdisciplinary Center for Theoretical Study, University of Science and Technology of China where part of this work was done.

### Appendix A: The proof of eq. (15)

In this appendix we will prove eq. (15). As in [12], we can use a $SL(2, \mathbb{C})$ transformation and a rescaling of $\tilde{\eta}$ to choose $\tilde{\eta}^1 = 0$ and $\tilde{\eta}^2 = 1$. Then we have

$$\phi_i = \tilde{\lambda}_{i2} \hspace{1cm} (68)$$

and

$$\frac{[i, j]}{\phi_i \phi_j} = \frac{\tilde{\lambda}_{i1} \tilde{\lambda}_{j2} - \tilde{\lambda}_{i2} \tilde{\lambda}_{j1}}{\tilde{\lambda}_{i2} \tilde{\lambda}_{j2}} = \frac{\tilde{\lambda}_{i1}}{\tilde{\lambda}_{j2}} - \frac{\tilde{\lambda}_{j1}}{\tilde{\lambda}_{j2}}. \hspace{1cm} (69)$$
If we do a rescaling of \( \tilde{\lambda}_{11} \) by \( \tilde{\lambda}_{12} \), i.e. by defining \( \varphi_i = \frac{\tilde{\lambda}_{11}}{\tilde{\lambda}_{12}} \), and also do a rescaling of \( \lambda_{ia} \) by \( 1/\tilde{\lambda}_{12} \), then eq. (15) becomes:

\[
F(\varphi) = \sum_{i=1}^{r-1} \sum_{l=\max\{i+3,r\}}^{n} \sum_{j=i+1}^{l-2} \sum_{k=j+1}^{l-1} (\varphi_i - \varphi_{i+1})(\varphi_j - \varphi_{j+1})
\]

\[
\times (\varphi_{k} - \varphi_{k+1})(\varphi_{l} - \varphi_{l+1}) \frac{\langle V_p, V_q \rangle^4}{\langle V_1, V_2 \rangle \langle V_2, V_3 \rangle \langle V_3, V_4 \rangle \langle V_4, V_1 \rangle}
\]

\[
= (\varphi_1 - \varphi_r)^4.
\]

where

\[
V_1 = \sum_{s=i+1}^{n+i} \lambda_s, \quad V_2 = \sum_{s=i+1}^{j} \lambda_s,
\]

\[
V_3 = \sum_{s=j+1}^{k} \lambda_s, \quad V_4 = \sum_{s=k+1}^{l} \lambda_s.
\]

There are also two constraints:

\[
V_1 + V_2 + V_3 + V_4 = \sum_{l=1}^{n} \lambda_l = 0,
\]

\[
\sum_{i=1}^{n} \lambda_i \varphi_i = 0,
\]

from momentum conservation.

From eq. (73) and eq. (74) we can solve \( \lambda_1 \) and \( \lambda_r \) in terms of the rest \( \lambda_i \)'s and all \( \varphi_j \)'s as:

\[
\lambda_1 = - \sum_{2 \leq j \leq n, j \neq r} \frac{\varphi_i - \varphi_r}{\varphi_1 - \varphi_r} \lambda_j,
\]

\[
\lambda_r = \sum_{2 \leq j \leq n, j \neq r} \frac{\varphi_i - \varphi_1}{\varphi_1 - \varphi_r} \lambda_j.
\]

By using the above result, the left hand side of eq. (70) can be considered as a function of \( \lambda_j \) (2 \( \leq \) \( j \) \( \leq \) \( n \), \( j \neq r \)) and all \( \varphi_j \). As a function of \( \varphi \) we will show that it is independent of \( \varphi_j \) for 2 \( \leq \) \( j \) \( \leq \) \( n \) and \( j \neq r \).

First we show that there is no pole terms for \( \varphi_s \rightarrow \infty, 2 \leq s \leq n-1, s \neq r \). We will show that every term in the l.h.s of eq. (70) will not tend to infinity when \( \varphi_s \rightarrow \infty \). We denote \( (\varphi_i - \varphi_{i+1})(\varphi_j - \varphi_{j+1})(\varphi_k - \varphi_{k+1})(\varphi_l - \varphi_{l+1}) \)
\( \varphi_{l+1} \) in eq. (70) as \( F(i, j, k, l) \) and \( \langle V_p, V_q \rangle^4/(\langle V_1, V_2 \rangle \langle V_2, V_3 \rangle \langle V_3, V_4 \rangle \langle V_4, V_1 \rangle) \) as \( A_4(V_1, V_2, V_3, V_4) \).

When \( \varphi_s \to \infty \), \( \lambda_1 \) and \( \lambda_r \) will grow as \( \varphi_s \) and other \( \lambda_i \)'s does not depend on \( \varphi_s \). \( V_1 \) and the \( V_i \) which includes \( \lambda_r \) as defined in eqs. (71) and (72) will tend to infinity as fast as \( \varphi_s \). \( V_p \) and \( V_q \) are independent of \( \varphi_s \). So the numerator of \( A_4(V_1, V_2, V_3, V_4) \) is independent of \( \varphi_s \).

Now we prove that \( \langle V_1, V_1 \rangle \) grows as \( \varphi_s \). From eq. (73) and eq. (76), we can write \( \lambda_1 \) and \( \lambda_r \) as \( \lambda_1 = a_{1s} \varphi_s \lambda_s + \mu_{1s} \) and \( \lambda_r = a_{rs} \varphi_s \lambda_s + \mu_{rs} \) respectively, where \( \mu_{1s} \) and \( \mu_{rs} \) is independent on \( \varphi_s \). Then \( \langle V_1, V_1 \rangle = \varphi_s \langle \lambda_s, a_{1s} \mu_{rs} - a_{rs} \mu_{1s} \rangle + O(\varphi_s^0) \) will grow as \( \varphi_s \) for generic \( \varphi_i, \lambda_j, 1 \leq j \leq n, j \neq r \).

The factor \( F(i, j, k, l) \) grows as \( \varphi_s^2 \) at most. Also one can check case by case and find the denominator of \( A_4(V_1, V_2, V_3, V_4) \) grows as \( \varphi_s^2 \) at least\(^5\). By combing all these results one sees that there is no pole terms for \( F(\varphi) \) as \( \varphi_s \to \infty \).

The next step is to show that all the finite pole terms in \( F(\varphi) \) are vanishing. The possible terms appear if any factor of \( \langle V_1, V_2 \rangle \langle V_2, V_3 \rangle \langle V_3, V_4 \rangle \langle V_4, V_1 \rangle \) is vanishing.

Let us consider first the vanishing of \( \langle V_1, V_2 \rangle \). We denote this set of \( V_1 \) and \( V_2 \) as \( v_1 \) and \( v_2 \):

\[
v_1 = \sum_{i=n_3+1}^{n_3+n_1} \lambda_i, \quad v_2 = \sum_{i=n_1+1}^{n_2} \lambda_i.
\quad (77)
\]

First let us consider the case when \( n_1 + 1 \leq r \leq n_2 \).

As one can see from Fig. 3 that there is contribution from summing over \( k \) and fixing \( i = n_1, j = n_2 \) and \( l = n_3 \).\(^6\) The residues (ignoring an overall factor \( \langle \varphi_{n_1} - \varphi_{n_1+1} \rangle \langle \varphi_{n_2} - \varphi_{n_2+1} \rangle \langle \varphi_{n_3} - \varphi_{n_3+1} \rangle \) for this pole terms are

\[
C_1 = \sum_{k=n_2+1}^{n_3-1} (\varphi_k - \varphi_{k+1}) \frac{\langle V_3, V_4 \rangle^3}{\langle v_2, V_3 \rangle \langle V_4, v_1 \rangle}.
\quad (78)
\]

Because \( \langle v_1, v_2 \rangle = 0, v_1 \) and \( v_2 \) are linearly dependent, we can assume that \( v_i = \alpha_i v_0, i = 1, 2 \), for some \( \alpha_i \) and \( v_0 \).

Using this result and \( v_1 + v_2 + V_3 + V_4 = 0 \), we have

\[
C_1 = \frac{(\alpha_1 + \alpha_2)^3}{\alpha_1 \alpha_2} \sum_{k=n_2+1}^{n_4-1} (\varphi_k - \varphi_{k+1}) \langle v_0, V_3 \rangle.
\quad (79)
\]

\(^5\)We note that when one of \( V_p \) and \( V_q \) includes only the term \( \lambda_s \), the denominator will grows as \( \varphi_s^2 \) because \( \langle V_1, \lambda_s \rangle \) and \( \langle V_i, \lambda_s \rangle \) are independent of \( \varphi_s \).

\(^6\)We note that \( V_3 \) and \( V_4 \) depend on \( k \): \( V_3 = \sum_{i=n_2+1}^{n_3} \lambda_i \) and \( V_4 = \sum_{i=n_1+1}^{n_2} \lambda_i \).
Figure 9: The pole terms $\langle v_1, v_2 \rangle$ from the factor $\langle V_1, V_2 \rangle$. There is a summation over $k$.

By using a little algebra, we can write the summation in eq. (79) as following

$$C_1 = \frac{(\alpha_1 + \alpha_2)^3}{\alpha_1 \alpha_2} \left( \sum_{k=n_2+1}^{n_3-1} \varphi_k \langle v_0, \lambda_k \rangle - \varphi_{n_3} \langle v_0, \sum_{m=n_2+1}^{n_3-1} \lambda_m \rangle \right). \quad (80)$$

Because $\langle v_0, \sum_{m=n_2+1}^{n_3} \lambda_m \rangle = \langle v_0, V_2 \rangle = 0$, we have $\langle v_0, \sum_{m=n_2+1}^{n_3-1} \lambda_m \rangle =$
\(-\langle v_0, \lambda_{n_3} \rangle\). Then

\[
C_1 = \frac{(\alpha_1 + \alpha_2)^3}{\alpha_1 \alpha_2} \langle v_0, \sum_{k=n_2+1}^{n_3} \varphi_k \lambda_k \rangle. \tag{81}
\]

Figure 10: The pole terms \(\langle v_1, v_2 \rangle\) from the factor \(\langle V_2, V_3 \rangle\). There is a summation over \(l\).

Unlike the special case discussed in [12], here for \(n_1 + 1 \leq r \leq n_2\), there are pole terms from the vanishing of the factor \(\langle V_2, V_3 \rangle\) in Fig. 10 by setting \(V_2 = v_2\) and \(V_3 = -v_1 - v_2\) and summing over \(l\). This gives the following contribution:

\[
C_2 = \sum_{l=n_3+1}^{n} \frac{(\varphi_l - \varphi_{l+1})}{\langle v_1 - V_4, v_2 \rangle \langle V_4, v_1 - V_4 \rangle} \langle -v_1 - v_2, V_4 \rangle^3
= \frac{(\alpha_1 + \alpha_2)^3}{\alpha_1 \alpha_2} \sum_{l=n_3+1}^{n} (\varphi_l - \varphi_{l+1}) \langle v_0, V_4 \rangle
= \frac{(\alpha_1 + \alpha_2)^3}{\alpha_1 \alpha_2} \langle v_0, \sum_{l=n_3+1}^{n} \varphi_l \lambda_l - \varphi_1 \sum_{m=n_3+1}^{n} \lambda_m \rangle. \tag{82}
\]

The third piece of the pole terms is from the vanishing of \(\langle V_3, V_4 \rangle\) in Fig. 11 by setting \(V_3 = v_2\) and \(V_4 = -v_1 - v_2\) and summing over \(i\). This give
Figure 11: The pole terms $\langle v_1, v_2 \rangle$ from the factor $\langle V_3, V_4 \rangle$. There is a summation over $i$.

the following contribution:

$$C_3 = \frac{(\alpha_1 + \alpha_2)^3}{\alpha_1 \alpha_2} \langle v_0, \varphi_1 \sum_{m=n_3+1}^{n_1} \lambda_m + \sum_{i=2}^{n_1} \varphi_i \lambda_i \rangle$$  \hspace{1cm} (83)

The last piece of the pole terms is from the vanishing of $\langle V_4, V_1 \rangle$ in Fig. 12 and Fig. 13 by setting $V_1 = v_1$ and $V_4 = -v_1 - v_2$ and summing over $j$. The contribution corresponds to the Fig. 12 is

$$C_4 = \frac{(\alpha_1 + \alpha_2)^3}{\alpha_1 \alpha_2} \langle v_0, \sum_{j=n_1+1}^{r-1} \varphi_j \lambda_j - \varphi_r \sum_{m=n_1+1}^{r-1} \lambda_m \rangle, \hspace{1cm} (84)$$
Figure 12: The pole terms $\langle v_1, v_2 \rangle$ from the factor $\langle V_4, V_1 \rangle$. There is a summation over $j$ from $n_1 + 1$ to $r - 1$.

Figure 13: The pole terms $\langle v_1, v_2 \rangle$ from the factor $\langle V_4, V_1 \rangle$. There is a summation over $j$ from $r$ to $n_2 - 1$.

and the contribution corresponds to the Fig. 13 is

$$C_5 = \frac{(\alpha_1 + \alpha_2)^3}{\alpha_1 \alpha_2} \langle v_0, \varphi_r \sum_{m=n_1+1}^{r} \lambda_j + \sum_{j=r+1}^{n_2} \varphi_j \lambda_j \rangle.$$  \hspace{1cm} (85)
By summing all these five contributions together, we have

\[ C_1 + C_2 + C_3 + C_4 + C_5 = \left( \frac{\alpha_1 + \alpha_2}{\alpha_1 \alpha_2} \right)^3 \langle v_0, \sum_{i=1}^{n} \varphi_i \lambda_i \rangle = 0. \] (86)

Figure 14: All of the possible pole terms are come from this kind of diagrams when \( 3 \leq r \leq n_1 \), but actually there is no singularity.

This prove that there is no pole terms for the function \( F(\varphi) \) when \( n_1 + 1 \leq r \leq n_2 \). The case for \( n_2 + 1 \leq r \leq n_3 \) is similar. The case for \( r = n \) or \( r = 2 \) is also similar and the algebra becomes a little bit easier because we need only consider three different kinds of diagram in these two cases as shown in [12]. When \( 3 \leq r \leq n_1 \), the situation is even easier because in this case all of the possible contribution to the pole terms is come from the diagrams in fig. [14].
but actually the numerator has a zero of order 4 while the denominator has a zero of order 1. So there is no singularity in every individual term. Similarly there is no pole terms when \( n_3 + 1 \leq r \leq n - 1 \). In summary we proved that all the finite pole terms in \( F(\varphi) \) are vanishing in all different cases.

So \( F(\varphi) \) is independent of \( \varphi_j \) for \( 2 \leq j \leq n \), \( j \neq r \). Now we compute \( F(\varphi) \) explicitly by choosing a special set of \( \varphi_j \) for \( 2 \leq j \leq n \), \( j \neq r \). A convenient choice is as follows:

\[
\varphi_2 = \cdots = \varphi_{r-1} = x, \varphi_{r+1} = \cdots = \varphi_n = y.
\]  

(87)

By using eq. (75) and eq. (76), we have

\[
\lambda_1 = \frac{(x - \varphi_r)\lambda + (y - \varphi_r)\mu}{\varphi_r - \varphi_1}, \quad \lambda_r = -\frac{(x - \varphi_1)\lambda + (y - \varphi_1)\mu}{\varphi_r - \varphi_1},
\]  

(88)

by setting \( \sum_{i=2}^{r-1} \lambda_i = \lambda \) and \( \sum_{j=r+1}^{n} \lambda_j = \mu \). In the following we will use the new variables \( x' \) and \( y' \) which we define as

\[
x' = \frac{x - \varphi_1}{\varphi_r - \varphi_1}, \quad y' = \frac{y - \varphi_r}{\varphi_r - \varphi_1},
\]  

(89)

then we have

\[
\frac{x - \varphi_1}{\varphi_r - \varphi_1} = x' + 1, \quad \frac{y - \varphi_r}{\varphi_r - \varphi_1} = y' + 1.
\]  

(90)

Now we show that for generic \( x \) and \( y \) (and generic \( \lambda_i \) which we don’t say explicitly) all the possible \( \langle V_1, V_2 \rangle, \langle V_2, V_3 \rangle, \langle V_3, V_4 \rangle \) and \( \langle V_4, V_1 \rangle \) for different choices of \( i, j, k \) and \( l \) are non-vanishing.

In order to do this, let’s define a matrix \( \{t_{ij}\}_{1 \leq i \leq n, 1 \leq j \leq 4} \). If \( \lambda_i \) is one of the terms in \( V_j \) then we define \( t_{ij} = 1 \). Otherwise we set \( t_{ij} = 0 \). Then

\[
V_j = \sum_{i=1}^{n} t_{ij} \lambda_i = \sum_{i=2}^{r-1} \lambda_i [t_{ij} + t_{1j} x' - t_{rj} (x' + 1)]
\]

\[
+ \sum_{i=r+1}^{n} \lambda_i [t_{ij} + t_{1j} y' - t_{rj} (y' + 1)].
\]  

(91)

So for generic \( x \), \( y \) and \( \lambda_i \), \( V_i \) and \( V_{i+1} \) are linearly independent and so \( \langle V_i, V_{i+1} \rangle \) is non-vanishing.

\footnote{The case when \( r = n \) or \( r = 2 \) is a little bit different, and it is done in [12].}
For our choice of $\varphi$, the possible non-vanishing factor for $(\varphi_i - \varphi_{i+1})(\varphi_j - \varphi_{j+1})(\varphi_k - \varphi_{k+1})$ is from $i = 1$, $j = r - 1$, $k = r$ and $l = n$ only. Then we have

$$F(\varphi) = (\varphi_1 - x)(x - \varphi_r)(\varphi_r - y)(y - \varphi_1)$$

$$\times \frac{\langle \lambda, \mu \rangle}{\langle \lambda_1, \lambda \rangle \langle \lambda, \lambda_r \rangle \langle \lambda_r, \mu \rangle \langle \mu, \lambda_1 \rangle}.$$  \hspace{1cm} (92)

By using eq. (88), we have

$$\langle \lambda_1, \lambda \rangle = -\frac{y - \varphi_r}{\varphi_r - \varphi_1} \langle \lambda, \mu \rangle,$$  \hspace{1cm} (93)

$$\langle \lambda, \lambda_r \rangle = -\frac{y - \varphi_1}{\varphi_r - \varphi_1} \langle \lambda, \mu \rangle,$$  \hspace{1cm} (94)

$$\langle \lambda_r, \mu \rangle = -\frac{x - \varphi_1}{\varphi_r - \varphi_1} \langle \lambda, \mu \rangle,$$  \hspace{1cm} (95)

$$\langle \mu, \lambda_1 \rangle = -\frac{x - \varphi_r}{\varphi_r - \varphi_1} \langle \lambda, \mu \rangle,$$  \hspace{1cm} (96)

and so we have

$$F(\varphi) = (\varphi_r - \varphi_1)^4.$$  \hspace{1cm} (97)

This completes the proof of eq. (15).

**Appendix B: The computation of $P(\Gamma)$**

In this appendix, we will give the proof of eq. (57). We assume that the off-shell graviton has positive helicity. The case when it has negative helicity is similar.

When $n = 3$, we have $\lambda_1 + \lambda_2 \phi_2 + \lambda_3 \phi_3 = 0$, so $\langle 1, 2 \rangle = \phi_3 \langle 2, 3 \rangle$, $\langle 3, 1 \rangle = \phi_2 \langle 2, 3 \rangle$. Then

$$A_3(1+, 2-, 3-) = \frac{1}{\phi_2^2 \phi_3^2} \langle 2, 3 \rangle^2 = \frac{p_1^2}{\phi_2^2 \phi_3^2} \langle 2, 3 \rangle [2, 3].$$  \hspace{1cm} (98)

There is only one inequivalent undirected tree with vertex set $\{2, 3\}$. There is only one edge $e_{23}$ in this tree. It is easy to see that

$$P(\Gamma) = p(2)p(3)p(e_{23}) = \phi_2^{-4} \phi_3^{-4} \left( \phi_2^2 \phi_3^2 \frac{\langle 2, 3 \rangle}{[2, 3]} \right) = \frac{1}{\phi_2^2 \phi_3^2} \langle 2, 3 \rangle [2, 3].$$  \hspace{1cm} (99)
Figure 15: The decomposition for the amplitude for gravitons using in the computation of $P(\Gamma)$.

So $M_3(1+, 2-, 3-) = p_1^2 P(\Gamma)$. This completes the proof for eq. (57) when $n = 3$. Assuming that it is true for all $k \leq n$, we will prove that it is also true for $k = n + 1$.

We use the diagram decomposition in Fig. 15 to calculate $A_{n+1}$. So we have

$$A_{n+1} = \sum_{\{i_1, \ldots, i_m\}} A_{m+1}(-q_1, i_1, \ldots, i_m) \frac{1}{q_1^2} \times A_{n-m+1}(-q_2, j_1, \ldots, j_{n-m}) \frac{1}{q_2^2} V_3(1, q_1, q_2),$$

where $i_1, \ldots, i_m$ are any $m (1 \leq m \leq n - 1)$ gravitons in $\{2, \ldots, n + 1\}$, $j_1, \ldots, j_{n-m}$ are the remaining $n - m$ ones. $q_1$ and $q_2$ are two internal lines with momenta $q_1 = \sum_{k=1}^m p_{i_k}$ and $q_1 = \sum_{k=1}^{n-m} p_{j_k}$ respectively. We denote $\{i_1, \ldots, i_m\}$ as $S_1$ and $\{j_1, \ldots, j_{n-m}\}$ as $S_2$. It is easy to see that when $m = 1$ ($m = n - 1$), if we understand $A_2(-q_1, i_1)$ ($A_2(-q_2, j_1)$) as $1/\phi_{i_1}^4$ ($1/\phi_{j_1}^4$), then these two degenerate cases are included correctly.
By using the assumed result for all less multi-graviton amplitudes, we can get

\[ A_{n+1} = \sum_{\Gamma_1, \Gamma_2} P(\Gamma_1)P(\Gamma_2)V_3(1, q_1, q_2), \]  

(101)

where \( \Gamma_1 \) and \( \Gamma_2 \) are two disjoint undirected trees subject to the constraint that the union of their vertex set are \( \{2, 3, \cdots, n\} \). (In this appendix, the summation over \( \Gamma_1 \) and \( \Gamma_2 \) is always understood to be under this constraint.) When \( m = 1 \) (\( m = n - 1 \)) the tree \( \Gamma_1 (\Gamma_2) \) includes only one vertex and there are no edges in \( \Gamma_1 (\Gamma_2) \). These degenerate cases are included correctly, too.

From eq. (56), we have

\[ V_3(1, q_1, q_2) = \langle\langle \lambda_{q_1}, \lambda_{q_2} \rangle \rangle^2 = \left( \sum_{i \in V_1, j \in V_2} \langle\langle \lambda_{p_i}, \lambda_{p_j} \rangle \rangle \right)^2 \]

\[ = \sum_{i, j \in V_1, k, l \in V_2} \langle\langle \lambda_{p_i}, \lambda_{p_k} \rangle \langle\langle \lambda_{p_j}, \lambda_{p_l} \rangle \rangle, \]  

(102)

where \( V_i \) is the vertex set \( V(\Gamma_i) \) of graph \( \Gamma_i \) \( (i = 1, 2) \). So we have

\[ A_{n+1} = \sum_{\Gamma_1, \Gamma_2} P(\Gamma_1)P(\Gamma_2) \sum_{i, j \in V_1, k, l \in V_2} \langle\langle \lambda_{p_i}, \lambda_{p_k} \rangle \langle\langle \lambda_{p_j}, \lambda_{p_l} \rangle \rangle. \]  

(103)

By denoting \( 2p_i \cdot p_j = \langle i, j \rangle [i, j] \) as \( s_{ij} \) and then using

\[ p_1^2 = \left( \sum_{i=2}^{n+1} p_i \right)^2 = \sum_{2 \leq i < j \leq n+1} s_{ij}, \]  

(104)

we get

\[ p_1^2 \sum_{\Gamma, V(\Gamma) = S(n+1)} P(\Gamma) = \sum_{\Gamma, V(\Gamma) = S(n+1)} P(\Gamma) \sum_{i, j \in V(\Gamma), i < j} s_{ij}. \]  

(105)

For any \( i, j \in V(\Gamma) \), there is an unique path in the tree \( \Gamma \) jointing \( i \) and \( j \). We denote this path as \( v_1 = i, v_2, \cdots, v_{k-1}, v_k = j \). By using the following identity:

\[ \frac{[i, j]}{\phi_i \phi_j} = \frac{[i, k]}{\phi_i \phi_k} + \frac{[k, j]}{\phi_k \phi_j}, \]  

(106)

we get

\[ \frac{[i, j]}{\phi_i \phi_j} = \sum_{s=1}^{k-1} \left[ s, s+1 \right] \frac{\phi_{v_s} \phi_{v_{s+1}}}{\phi_{v_s} \phi_{v_{s+1}}}. \]  

(107)
So

\[
P(\Gamma)_{s_{ij}} = P(\Gamma)_{i,j} \phi_{i,\phi_j} \frac{[i,j]}{\phi_{i,\phi_j}}
= \sum_{s=1}^{k-1} P(\Gamma)_{i,j} \phi_{i,\phi_j} \frac{[v_s, v_{s+1}]}{\phi_{v_s,\phi_{v_{s+1}}}^2}.
\]

(108)

If we move away an edge from a tree, we can get two disjoint trees. Conversely, assuming that \(\Gamma_1\) and \(\Gamma_2\) are two disjoint trees, if we connect one vertex in \(\Gamma_1\) with another vertex in \(\Gamma_2\) by an edge, we get a bigger tree. We denote the two trees obtained by moving away the edge \(e_{v_s, v_{s+1}}\) as \(\Gamma_1(v_s)\) and \(\Gamma_2(v_s)\). Then we have

\[
P(\Gamma)_{s_{ij}} = \sum_{s=1}^{k-1} P(\Gamma_1(v_s)) P(\Gamma_2(v_s)) \frac{[v_s, v_{s+1}]}{[v_s, v_{s+1}]} \phi_{v_s,\phi_{v_{s+1}}}^2 \phi_{i,\phi_j} \frac{[v_s, v_{s+1}]}{\phi_{v_s,\phi_{v_{s+1}}}}
\]

(109)

From this we can get

\[
\sum_{\Gamma, V(\Gamma) = S(n+1)} P(\Gamma) s_{ij}^2 = \sum_{\Gamma, V(\Gamma) = S(n+1)} P(\Gamma) \sum_{i,j \in V(\Gamma), i<j} s_{ij}
= \sum_{\Gamma_1, \Gamma_2} P(\Gamma_1) P(\Gamma_2) \sum_{i,j \in V_1, k,l \in V_2} \langle \lambda_{p_i}, \lambda_{p_k} \rangle \langle \lambda_{p_j}, \lambda_{p_l} \rangle
= A_{n+1},
\]

(110)

as announced. This completes the proof of eq. (57) by mathematical induction.
