Abstract: We obtain the characteristic equation for the nonlinear Born-Infeld electrodynamics. This equation has the form of the characteristic equation for the linear electrodynamics in some effective Riemann space. The effective metric include the energy-momentum tensor components of electromagnetic field. We study a distortion of light beams by the action of some distant solitons. This distortion corresponds to attraction with the solitons and looks like the gravitational distortion.
1. Introduction

The dynamics of solitons looks like the dynamics of particles. Specifically, the electromagnetic solitons behave like gravitating particles if we consider the second order by a field of distant solitons [1, 2]. In the first order of this case we have the Lorentz force.

At the moment we reason that the nonlinear electrodynamics with singularities discussed in the article [3] is best suited to this analogues. In this article we had considered a modernized Born-Infeld action that include a singular part with $\delta$-functions. This is equivalent also to introducing boundary conditions at points. These points behave like point charged particles. In this case we have the space with a non-trivial topology.

A subject of the present article is a study of light beams distortion as nonlinear effect of the model.

2. Field equations outside of the singularities

In this article we consider the field equations outside of the singularities that is the purely Born-Infeld model. Thus the system of equations may by written in the following form:

\[
\begin{align*}
\text{div}B &= 0 \\
\text{div}D &= 0 \\
\partial_0 B + \text{rot}E &= 0 \\
-\partial_0 D + \text{rot}H &= 0
\end{align*}
\]

where

\[
\begin{align*}
D &= \frac{1}{\mathcal{L}} (E + \alpha^2 \mathcal{J}B) \\
H &= \frac{1}{\mathcal{L}} (B - \alpha^2 \mathcal{J}E) \\
E &= \frac{1}{\mathcal{L}} (D - \alpha^2 \mathcal{J}H) \\
B &= \frac{1}{\mathcal{L}} (H + \alpha^2 \mathcal{J}D)
\end{align*}
\]
\[
\mathcal{L} = \sqrt{|1 - \alpha^2 \mathcal{I} - \alpha^4 \mathcal{J}^2|} \quad , \quad \mathcal{L} \equiv \sqrt{|1 - \alpha^2 \mathcal{T} - \alpha^4 \mathcal{J}^2|} \quad ,
\]
\[
\mathcal{I} = \mathcal{E}^2 - \mathcal{B}^2 \quad , \quad \mathcal{T} = \mathcal{H}^2 - \mathcal{D}^2 \quad , \quad \mathcal{J} = \mathcal{F} = \mathcal{E} \cdot \mathcal{B} = \mathcal{H} \cdot \mathcal{D} \quad .
\]

(2.3)

Here we suppose that the components of metric are \( g_{00} = -1 \), \( g_{0i} = 0 \).

We can use only the second block of eqs. (2.1) for a problem with initial conditions. For a cartesian coordinate system we can write the following system:

\[
\left\{ 
\begin{array}{l}
-C_{DE}^{ij} \frac{\partial E_i}{\partial x^0} - C_{DB}^{ij} \frac{\partial B_j}{\partial x^0} + \varepsilon_{ijk} C_{HE}^{kl} \frac{\partial E_l}{\partial x^j} + \varepsilon_{ijk} C_{HB}^{kl} \frac{\partial B_l}{\partial x^j} = 0 \\
\end{array}
\right.
\]

(2.4)

where

\[
\begin{align*}
C_{DE}^{ij} &= \delta^{ij} + \alpha^2 (D_i D_j + B_i B_j) \\
C_{DB}^{ij} &= \alpha^2 (B_i E_j - D_i H_j) \\
C_{HB}^{kl} &= \delta^{kl} - \alpha^2 (H_k H_l + E_k E_l) \\
C_{HE}^{kl} &= \alpha^2 (D_k H_l - B_k E_l)
\end{align*}
\]

and the Latin indexes take the values 1, 2, 3.

Let us write the system of equations (2.4) in the following matrix form:

\[
Q^\mu \frac{\partial}{\partial x^\mu} \left( \begin{array}{c}
\mathcal{E} \\
\mathcal{B}
\end{array} \right) = 0 \quad ,
\]

(2.6)

where \((6 \times 6)\) matrix \(Q^\mu = Q^\mu (\mathcal{E}, \mathcal{B})\) may be easy obtained from eqs. (2.4), (2.5).

3. Characteristic equation

The characteristic equation for the system of such type ((2.4) or (2.6)) is given by the following relation [4]:

\[
\det(Q^\mu k_\mu) = 0 \quad ,
\]

(3.1)

where

\[
k_\mu \equiv \frac{\partial S}{\partial x^\mu}
\]

(3.2)

and \(S(x) = 0\) is the equation of a characteristic surface.

For the system (2.4, 2.6) we have the following expressions:

\[
\det(Q^\mu k_\mu) = \frac{(k_0)^2}{\mathcal{L}^2} \left[ \left( h^{\mu\nu} - \alpha^2 f^{\mu\rho} f_{\nu}^{\rho} \right) k_\mu k_\nu \right]^2 
\]

(3.3)

\[
= (k_0)^2 \mathcal{L}^2 \left[ \left( h^{\mu\nu} - \alpha^2 f^{\mu\rho} f_{\nu}^{\rho} \right) k_\mu k_\nu \right]^2 
\]

(3.4)

\[
= (k_0)^2 \left[ \left( h^{\mu\nu} - \alpha^2 \mathcal{T}^{\mu\nu} \right) k_\mu k_\nu \right]^2 
\]

(3.5)
where \( h_{11} = h_{22} = h_{33} = - h_{00} = 1 \), \( h_{\mu \nu} = 0 \) for \( \mu \neq \nu \);
the Greek indexes take the values \( 0, 1, 2, 3 \);

\[
F^{\mu \nu} = - \frac{1}{2} \varepsilon^{\mu \nu \rho \sigma} F_{\rho \sigma} \quad , \quad F_{i0} = E_i \quad , \quad F_{ij} = \varepsilon_{0ijkl} B^l ,
\]

(3.6)

\[
f^{\mu \nu} = \frac{1}{\alpha^2} \frac{\partial L}{\partial F_{\mu \nu}} \quad , \quad f^{0i} = D^i \quad , \quad f^{ij} = - \varepsilon^{0ijkl} H_l ,
\]

(3.7)

\[
T^{\mu \nu} \equiv f^{\mu \rho} F_{\nu \rho} - \frac{1}{\alpha^2} (\mathcal{L} - 1) h^{\mu \nu} ,
\]

(3.8)

\( \varepsilon_{0123} = 1, \varepsilon^{0123} = -1 \), \( T^{\mu \nu} \) are the metric energy-momentum tensor components [3].

Suppose \( k_0 \neq 0 \). Then, we have the following very interesting form of the characteristic equation generalized to the case of any metric:

\[
(g^{\mu \nu} - \alpha^2 T^{\mu \nu}) k_\mu k_\nu = 0 .
\]

(3.9)

4. Distortion of beams

From definition (3.2) it follows that \( \partial_\mu k_\nu - \partial_\nu k_\mu = 0 \); whence we get (see also [5])

\[
\frac{dk}{dx^0} = - \nabla W(k, x) ,
\]

(4.1)

where

\[ - k_0 \equiv \omega = W(k, x) \]

(4.2)

is a form of the characteristic equation, that may be obtained from the form of type (3.9). Here the full derivative on time is defined as

\[
\frac{dk_i}{dx^0} \equiv \frac{\partial k_i}{\partial x^0} + V^j \frac{\partial k_i}{\partial x^j} ,
\]

(4.3)

where \( V^j \equiv \frac{\partial W}{\partial k_j} \) are the components of group velocity.

The vector \( k \) is normal to the two-dimensional surface \( S(x^0, x) = 0 \) in any moment of time. Thus the equation (4.1) may be called the beam one.

From the characteristic equation (3.9) it follows the expression for the function \( W \).

\[
W = \frac{\alpha^2 T^{0i} k_i \pm \sqrt{(\alpha^2 T^{0i} k_i)^2 + (1 + \alpha^2 T^{00}) (k^2 - \alpha^2 T^{ij} k_i k_j)}}{1 + \alpha^2 T^{00}} .
\]

(4.4)

Let us express the function \( W \) (4.4) as a power series in \( \alpha^2 \). This is correspond to the small field approximation \( |\alpha E| \ll 1, |\alpha B| \ll 1 \). Here we disregard the terms with \( \alpha^4 \) and higher ones. Thus we obtain

\[
W = \alpha^2 T^{0i} k_i \pm |k| \left[ 1 - \frac{\alpha^2}{2} \left( T^{00} + T^{ij} \frac{k_i k_j}{k^2} \right) \right] .
\]

(4.5)
Substituting (3.8) for $T_{\mu \nu}$ in (4.5), using (3.6), (3.7), and ignoring $\alpha^4$ terms, we get

$$W = \alpha^2 (\mathbf{E} \times \mathbf{B}) \cdot \mathbf{k} \pm \left\{ |\mathbf{k}| - \frac{\alpha^2}{2|\mathbf{k}|} [(\mathbf{E} \times \mathbf{k})^2 + (\mathbf{B} \times \mathbf{k})^2] \right\}$$

(4.6)

Now we consider the propagation of a low-amplitude high-frequency electromagnetic wave in the presence of some given field. We can consider a field of some distant solitons as the given field.

The model (2.1), (2.2) has the following plane wave solution:

$$\tilde{\mathbf{E}} = \frac{1}{2} \left( \mathbf{u} e^{i\Theta} + \mathbf{u}^* e^{-i\Theta} \right), \quad \tilde{\mathbf{B}} = \frac{1}{2} \mathbf{k} \times \left( \mathbf{u} e^{i\Theta} + \mathbf{u}^* e^{-i\Theta} \right),$$

(4.7)

where $\Theta = \omega x^0 - \mathbf{k} \cdot \mathbf{x}$, $\omega^2 = \mathbf{k}^2$, $\mathbf{u}$ is a complex vector amplitude that $\mathbf{u} \cdot \mathbf{k} = 0$, $\bar{\mathbf{k}} \equiv \mathbf{k} / |\mathbf{k}|$. The field configuration (4.7) describe the plane wave with any polarization.

We find a solution of equation (2.6) in the following form:

$$(\mathbf{E} \mathbf{B}) = (\tilde{\mathbf{E}} \tilde{\mathbf{B}}) + (\mathbf{E} \mathbf{B})$$

(4.8)

where $\mathbf{E}$, $\mathbf{B}$ is a given field and we suppose that the phase $\Theta(x)$ of the solution (4.7) is a some unknown function and $k_\mu \equiv \partial \Theta / \partial x^\mu$ ($\omega \equiv -k_0$).

We suppose also that $(\tilde{\mathbf{E}} \tilde{\mathbf{B}}) \ll (\mathbf{E} \mathbf{B})$ and $\omega \gg \left| \partial \mathbf{E} / \partial x^\mu \right| / |\mathbf{E}|$.

Then substituting (4.8) in (2.6), we get

$$Q^\mu k_\mu \left( \mathbf{u} / \mathbf{k} \times \mathbf{u} \right) = 0,$$

where $Q^\mu = Q^\mu(\mathbf{E}, \mathbf{B})$.

This equation has non-trivial solutions when $\det(Q^\mu k_\mu) = 0$. Thus we have the characteristic equation as dispersion relation. If in addition $|\alpha \mathbf{E}| \ll 1$, $|\alpha \mathbf{B}| \ll 1$, then we have the dispersion function $W = W(k, \mathbf{E}, \mathbf{B})$ in the form (4.5) or (4.6).

The characteristic equation (3.9) or dispersion relation $\omega = W(k, \mathbf{E}, \mathbf{B})$ define a family of surfaces $S = \Theta = \text{const}$. We can introduce a curvilinear coordinates $\{x^\gamma\}$, that $x'^1$ is perpendicular to these surfaces. Then $k'_2 = k'_3 = 0$. Let us define the direction of the axis $x'^1$ that $k'_1 = |\mathbf{k}|$.

The phase velocity $\mathbf{v}$ of wave satisfy the equation $W - \mathbf{k} \cdot \mathbf{v} = 0$. Using (4.8), for the coordinate system $\{x^0, x'\}$ we obtain the following values of the phase velocity:

$$v_+ = 1 - \frac{\alpha^2}{2} \left[ (E'_2 - B'_3)^2 + (E'_3 + B'_2)^2 \right],$$

$$v_- = 1 - \frac{\alpha^2}{2} \left[ (E'_2 + B'_3)^2 + (E'_3 - B'_2)^2 \right],$$

(4.9)

where $|\mathbf{v}| = v_+$ for the wave that propagate in the positive direction of the axis $x'^1$, $|\mathbf{v}| = v_-$ for the wave that propagate in the opposite direction.
As we see, the two magnitudes of the phase velocity less than the speed of light. These magnitudes decrease when the given field increase. Thus according to the beam equation (4.1) we have the light beam distortion corresponding to attraction with distant solitons.

5. Conclusion

We have obtained the characteristic equation (3.9) for the Born-Infeld nonlinear electrodynamics. This equation has the form of the characteristic equation for the linear electrodynamics $\tilde{g}^{\mu\nu}k_{\mu}k_{\nu} = 0$ in some effective Riemann space. The effective metric include the energy-momentum tensor components of electromagnetic field $\tilde{g}^{\mu\nu} = g^{\mu\nu} - \alpha^2 T^{\mu\nu}$. According to this equation we have the distortion of light beams that corresponds to attraction with distant solitons. This looks like the gravitational distortion.

This property of light beams for the nonlinear model (2.1), (2.2) are in general agreement with the results obtained previously for motion of solitons [2]. But the motion of the solitons with singularities [3] need further consideration.
