A TQFT FOR WORMHOLE COBORDISMS
OVER THE FIELD OF RATIONAL FUNCTIONS

Patrick M. Gilmer
Louisiana State University

Abstract. We consider a cobordism category whose morphisms are punctured connect sums of $S^1 \times S^2$’s (wormhole spaces) with embedded admissibly colored banded trivalent graphs. We define a TQFT on this cobordism category over the field of rational functions in an indeterminant $A$. For $r$ large, we recover, by specializing $A$ to a primitive 4th root of unity, the Witten-Reshetikhin-Turaev TQFT restricted to links in wormhole spaces. Thus, for $r$ large, the $r$th Witten-Reshetikhin-Turaev invariant of a link in some wormhole space, properly normalized, is the value of a certain rational function at $e^{\frac{\pi i}{2r}}$. We relate our work to Hoste and Przytycki’s calculation of the Kauffman bracket skein module of $S^1 \times S^2$.

7/17/95

Introduction

We wish to consider links and graphs in a connected sum of $S^1 \times S^2$’s. Borrowing a phrase from the physicists, we will use the term ‘wormhole space’ to describe this kind of oriented 3-manifold with a relatively simple topology. Let $\mathbb{Q}(A)$ denote the field with involution consisting of the rational functions in the indeterminant $A$, with involution given by sending $A$ to $A^{-1}$.

In section one, we associate to a framed link $L$ in a wormhole space $M$ an invariant $< L > \in \mathbb{Q}(A)$. This generalizes the Kauffman Bracket [K] version of the Jones polynomial [J]. Let $G \subset M$ be a banded trivalent graph in the sense of [BHMV] (4.5) with an admissible coloring where the set of colors is taken to be all nonnegative integers. We will also define $< G > \in \mathbb{Q}(A)$. Here we make use of Roberts’ [R] fusion technique for simplifying bracket calculations. The well-definedness of the invariant rests ultimately on the well-definedness of the Witten-Reshetikhin-Turaev invariant [W] [RT]. See also [L] and [KL].

In section two, we define the related TQFT using the universal construction given in [BHMV]. We describe now the cobordism category $\mathcal{C}$ on which the TQFT is defined. A punctured wormhole space is a wormhole space with the interiors of some smooth closed 3-balls deleted. The boundary of a punctured wormhole space is a collection of 2-spheres. A punctured wormhole space with a properly embedded admissibly colored graph $(M, G)$ has boundary a disjoint union of 2-spheres with colored banded points. The objects of $\mathcal{C}$ are disjoint unions of 2-spheres with colored banded points. We also include the empty surface. A morphism from object $\Sigma_1$ to object $\Sigma_2$ is a triple $(M, G, f)$. Here $f$ is a diffeomorphism of $\partial(M, G)$ to $-\Sigma_1 \coprod \Sigma_2$. 
and $M$ is a punctured wormhole space or a disjoint union of punctured wormhole spaces or is the empty set. It is pleasant that no additional further structure such as a 2-framing or $p_1$ structure is needed. This is because our 3-manifolds are so simple. Since $\langle >$ is a multiplicative involutive invariant, the universal construction provides a cobordism generated quantization functor from $C$ to the category of vector spaces over $\mathbb{Q}(A)$. We show that the vector spaces are finite dimensional and that the tensor product axiom holds. Thus we have a TQFT $[A_1,A_2]$ which assigns $V(\Sigma)$ to an object $\Sigma$ and $Z_M: V(\Sigma_1) \rightarrow V(\Sigma_2)$ to a morphism $M$ from $\Sigma_1$ to $\Sigma_2$. If $\Sigma$ is the 2-sphere with $2k$ banded points all colored one, the $\dim(V(\Sigma))$ is the $k$th Catalan number. A version of this TQFT with many fewer objects and morphisms was introduced in [G,§4].

Hoste and Przytycki [HP] calculated $S(S^1 \times S^2)$, the Kauffman bracket skein module of $S^1 \times S^2$. $S(S^1 \times S^2)$ as a module over $\mathbb{Z}[A,A^{-1}]$ has a rank one free part, and some torsion. Thus a framed link in $S^1 \times S^2$ determines a Laurent polynomial in $A$. In section 3, we show that this polynomial agrees with our $\langle L \rangle$. However our work provides an alternative method of calculating the Hoste-Przytycki polynomial. This polynomial is also (up to sign) the penultimate coefficient of $\Gamma(L)$, defined in [G]. The invariant $\langle L \rangle$ is new for links in a connected sum of more than one $S^1 \times S^2$. The fourth section gives two worked examples.

We think that the TQFT introduced here is useful from a pedagogical point of view for the following reasons. On the one hand, the objects and morphisms of the cobordism category are simple topological spaces without any extra structure such as a 2-framing or $p_1$ structure. On the other hand, the theory is not completely trivial either.

§1 Graphs in a wormhole space

Let $r$ be an integer greater than two, let $k$ denote $r-2$. By graph, we will mean a trivalent banded colored graph as above. Let $G$ be a graph in a wormhole space $M$. Suppose that $k$ is greater than all the colors on $G$. Let $Z_r(M,G)$ denote the Witten-Reshetikhin-Turaev invariant. This is $I_{A_r}(M,L)$ evaluated at the element of $S(S^1 \times I)^{\#L}$ given by taking $S_i(\alpha)$ on a component colored $i$ where $L$ is the colored link obtained by expanding of $G$ evaluated [L]. We let $A_r$ denote $e^{\pi i/2}$. Also $Z_r(M,G)$ is $\langle M,G \rangle_{2p}$, where $M$ has been given a $p_1$ structure whose $\sigma$ invariant is zero [BHMV][MV]. We let

$$\langle G \rangle_r = \frac{Z_r(M,G)}{Z_r(M)}$$

$M$ is given by zero framed surgery on the unlink. The number of components of the unlink is the number of $S^1 \times S^2$ summands. We mark the components of the unlink with dots to indicate along which components 0-framed 1-surgery is to be performed, thinking perhaps of doing a 0-surgery along two three balls on ether side of the spanning disk [Ki,p.5]. Thus $(M,G)$ may be described by a trivalent colored graph drawn on blackboard with standard diagram of unlink whose components have been dotted. We may assume that $G$ is transverse to the disks which bound the components of the unlink. Thus $Z_r(M,G)$ is the generalized bracket evaluation [KL] of this diagram after replacing each component of the unlink with the $\omega_{2r}$ of [BHMV]. $Z_r(M)$ is simply the generalized bracket evaluation of the unlink after replacing each dotted component with $\omega_2$. Thus if we were to change $\omega_2$ by a scale factor $\lambda$, $\omega_{2r}$ in $Z_r(M,G)$ would be replaced by $\lambda^{r-1}\omega_{2r}$ in $Z_r(M,G)$.
factor in the above computation, \(< G >_r\) would remain unchanged. Thus we could as well take \(\omega\) to be Lickorish’s \(\omega = \sum_i = \Delta_i S_i(\alpha)\) or \([\text{BHMV}]\)’s \(\Omega_2\).

Suppose the sum of the colors on the strands of \(G\) which pass through the disks is less than or equal to \(k\). Then we may use recoupling theory to rewrite the evaluation as a linear combination of evaluations where at most a single strand passes through each disk. This is called fusion. Then we may discard all the terms in the linear combination where the single strand has a nonzero color using Lickorish’s Lemma \([L, \text{Lemma } 6]\). This method of simplification is due to Roberts \([R, \text{Figure } 7, \text{Figure } 16]\) \([\text{KL, §12.11}]\). In our situation, it is important to see that the above simplification can be made independent of \(r\), as long as \(k\) is greater than or equal to the sum of colors passing through each disk. One now has a linear combination of trivalent colored graphs completely unlinked from the unlink. Thus \(< G >_r\) is given by the bracket evaluation of the graph after we delete the unlink. Let \(G'\) denote this new trivalent graph. \(< G >_r\) is given by the bracket evaluation of \(G'\) after we set \(A = A_r\).

Let \(< G > \in \mathbb{Q}(A)\) be the bracket evaluation of \(G'\). Then \(< G >_r\) is simply \(< G >\) evaluated at \(A = A_r\). Since by, say, \([\text{BHMV}]\) or \([L]\), \(< G >_r\) is a well defined isotopy invariant of \(G\), we can conclude that \(< G > \in \mathbb{Q}(A)\) is also. Here we use the elementary fact that if two rational functions agree at infinitely many distinct points then they must agree. This is an immediate consequence the fundamental theorem of algebra. It is important to realize that this argument shows that the result of calculating \(< G >\) as above does not depend on the original surgery description of \(M\) or on any choices made in performing fusion.

We note that if \(L\) is a link diagram, then it describes a framed link in the wormhole space \(S^3\). If we color this framed link one, we get a graph in \(S^3\) which we also denote by \(L\). In this situation \(< L >\) is the ordinary Kauffman bracket \([K]\) of the link diagram \(L\), which in turn is version of the Jones polynomial \([J]\). Thus \(< G > \in \mathbb{Q}(A)\) generalizes the Kauffman bracket or Jones polynomial of links in \(S^3\) to graphs in a wormhole space.

Lemma (1.1). If \(G \subset M\) meets an embedded 2-sphere \(S \subset M\) in a single non-zero colored point, then \(< G >\) is zero.

Proof. Cut \(M\) along \(S\) and attach two 3-disks to obtain a space \(M'\). If \(M'\) is connected, then \(M'\) is a wormhole space and \(M\) is obtained from \(M'\) by a 0-surgery. In this case Lickorish’s lemma shows \(< G >_r\) to be zero for \(r\) large. Thus \(< G >\) must be zero.

If \(M'\) is disconnected, then \(M'\) is the disjoint union of two wormhole spaces and \(M\) is obtained by taking their connected sum. Now \(< G >_r\) is zero for \(r\) large, making use of one basic properties of the Temperley-Lieb idempotents \(f^{(n)} e_i = 0\) \([L, \text{Lemma } 1]\). Thus \(< G >\) must be zero. \(\Box\)

This invariant is extended multiplicatively to disjoint union of wormhole spaces with graphs. This invariant is involutive: \(< -(M,g) >= < (M,g) >\).

§2 A TQFT

Consider the cobordism category \(\mathcal{C}\) described in the introduction. \(< >\) is an involutive multiplicative invariant on the closed objects of \(\mathcal{C}\). The universal construction of Blanchet, Habegger, Masbaum, and Vogel then provides a cobordism generated quantization functor \((Z, V)\) to the category of vector spaces over \(\mathbb{Q}(A)\).
To show that \((Z, V)\) is a TQFT we must show that the tensor product axiom holds, and that the vector spaces associated to surfaces are finite dimensional. Recall elements of \(V(\Sigma)\) are equivalence classes of linear combinations of graphs in a punctured wormhole space whose boundary is \(\Sigma\). We note that \(V(\Sigma)\) comes equipped with a nonsingular Hermitian form \(<, >_{\Sigma}\).

**Lemma (2.1).** Let \(\Sigma\) be an object of \(\mathcal{C}\). Let \(N\) be a punctured 3-sphere with boundary the underlying manifold of \(\Sigma\). \(V(\Sigma)\) is generated by graphs in \(N\).

**Proof.** Let \((N, G)\) be a Wormhole space with graph whose boundary is \(\Sigma\). We may represent \(G\) by a graph in a punctured 3-sphere \(N'\) together with a dotted unlink. Applying the method of calculation in §1, we obtain a linear combination of graphs \(G'\) in \(N'\). Then the conjugate linear form \(< (N, G), >_{\Sigma} = < (N', G'), >_{\Sigma}\). Thus \((N, G)\) and \((N', G')\) represent the same element in \(V(\Sigma)\). □

**Lemma (2.2).** The natural map \(V(\Sigma_1) \otimes V(\Sigma_2) \to V(\Sigma_1 \coprod \Sigma_2)\) is surjective.

**Proof.** Let \((N, G)\) be a punctured 3-sphere with graph whose boundary is \(\Sigma_1 \coprod \Sigma_2\). Let \(S\) be a 2-sphere in \(N\) such that \(\Sigma_1\) and \(\Sigma_2\) lie in different components of \(N - S\). Let \(N'\) denote \(N\) surgered along \(S\). We may use fusion to represent the same element of \(V(\Sigma_1 \coprod \Sigma_2)\) as \((N, G)\) by a linear combination of graphs in \(N\) which each meet \(S\) in at most a single point. By Lemma (1.1), we may discard those which meet \(S\) in a single point. Let \(G'\) be the resulting linear combination of graphs in \(N'\). \(< (N, G), >_{\Sigma} = < (N', G'), >_{\Sigma}\). Thus \((N, G)\) and \((N', G')\) represent the same element in \(V(\Sigma)\). But such an element is in the image of \(V(\Sigma_1) \otimes V(\Sigma_2)\). □

Let \(\Sigma\) be a 2-sphere with some banded colored points \(\ell\). \(S\) is the boundary of a 3-ball \(B\). Let \(\mathcal{G}\) be an embedded trivalent (noncolored) tree in \(B\), such that \(\mathcal{G} \cap S = \ell\). Admissible colorings of \(G\) give graphs in \(B\) and thus elements of \(V(\Sigma, \ell)\). As in [BHMV] (see also [KL, Chapter 7]), one may show:

**Lemma (2.3).** The set of admissible colorings of a fixed tree \(\mathcal{G}\) as above forms an orthogonal basis for \(V(\Sigma)\) with respect to the Hermitian form \(<, >_{\Sigma}\).

**Theorem (2.4).** \((Z, V)\) is a TQFT.

**Proof.** By Lemmas (2.2) and Lemma (2.3), \(V(\Sigma)\) is finite dimensional for any \(\Sigma\). If we equip \(V(\Sigma_1) \otimes V(\Sigma_2)\) with the tensor product of the forms on \(V(\Sigma_1)\) and \(V(\Sigma_2)\), the map \(V(\Sigma_1) \otimes V(\Sigma_2) \to V(\Sigma_1 \coprod \Sigma_2)\) is an isometry, and thus injective. Thus the map is an isomorphism. □

**Proposition (2.5).** If \(\Sigma\) is a sphere with \(2n\) points colored one, then \(V(\Sigma)\) is given in the obvious way by the set of diagrams in the disk without without crossings and with boundary \(2n\) fixed points. Thus \(\dim V(\Sigma)\) is the \(n\)th Catalan number \(c(n) = \frac{1}{n+1} \left( \frac{2n}{n} \right)\).

**Proof.** Using the Kauffman relations, it is clear that this set generates \(V(\Sigma)\). Consider the matrix we get when we pair this set of elements against itself under \(<, >_{\Sigma}\). Its determinant is easily seen to be a polynomial of degree \(n\) \(c(n)\) in \(d = -A^2 - A^{-2}\). So this set of elements is linearly independent. □

§3 Relation to Hoste and Przytycki’s Work

\(S(S^1 \times S^2)\) modulo its \(\mathbb{Z}[A, A^{-1}]\)-torsion submodule is isomorphic to \(\mathbb{Z}[A, A^{-1}]\), \([HP]\). This quotient can be canonically identified with \(\mathbb{Z}[A, A^{-1}]\). The equivalence
class of the free generator $1$ given by the empty link is identified with one. Following Hoste and Przytycki, we let $\pi$ denote the projection from $S(S^1 \times S^2)$ to this quotient which has canonically identified with $\mathbb{Z}[A,A^{-1}]$. Thus we have $\pi : S(S^1 \times S^2) \to \mathbb{Z}[A,A^{-1}]$. The application of $\langle \cdot \rangle$ to links $L$ in $S^1 \times S^2$ colored one defines a $\mathbb{Z}[A,A^{-1}]$-module homomorphism to $\mathbb{Q}(A)$ which must vanish on the torsion submodule. Let $\emptyset$ denote the empty link in $S^1 \times S^2$, then $\langle \emptyset \rangle = \pi(1) = 1 \in \mathbb{Z}[A,A^{-1}]$. This proves:

**Proposition (3.1).** If $L$ is a framed link in $S^1 \times S^2$ colored one, then $\langle L \rangle = \pi(L)$.

The element of $S(S^1 \times S^2)$ given by $m$ standardly framed longitudes is denoted $z^m$. Let $L_m$ denote this link viewed now as a closed morphism of $C$. We have by [BHMV,(1.2)], $\langle L_m \rangle = \text{Trace}(\text{Id}_{S_m}) = \dim V(S_m)$. Using Proposition (2.5), we have a new proof of [HP,Corollary 5]

**Corollary (3.2)(Hoste-Przytycki).** $\pi(z^{2n+1}) = 0$, and $\pi(z^{2n})$ is the $n$th Catalan number.

We remark that it follows from Proposition (3.1) that, for a link $L$ colored one in $S^1 \times S^2$, $\langle L \rangle$ actually lies in $\mathbb{Z}[A,A^{-1}]$. This also follows from the fact shown in [G] that $\Gamma(T)$ has coefficients in $\mathbb{Z}[A,A^{-1}]$. The first example in §4 shows this is not true for a knot colored one in the connected sum of two $S^1 \times S^2$s.

Although a relationship has been given between [HP] and [G, §4], the lower bounds given for the wrapping number of links in $S^1 \times S^2$ given by these two papers still seem different, but a detailed comparison has not been made.

### §4 Two Examples

![Image of two examples](image.png)

Using the fusion identity on the left of Figure 1, we compute $\langle K \rangle = \frac{1}{d}$ for the knot in the connected sum of two $S^1 \times S^2$s pictured on the left.

Consider the link $T$ in $S^2 \times I$ pictured on the left of Figure 2. In [G], we calculated a matrix for $Z(S^2 \times I,T)$ with respect to the basis given in Proposition (2.5). The trace of this matrix was $A^{-12} - A^{-8} - A^{-4} + 1 - 2A^4 + 4A^6 - 4A^8$. This...
must be $< L >$ where $L$ is the link in $S^1 \times S^2$ pictured on the right of Figure 2.

![Figure 2](image1.png)

We will now calculate $< L >$ directly by the method described in §1. We will make use of the fusion formula given in Figure 3. All unlabelled and undotted strands are colored one.

![Figure 3](image2.png)

Thus $< L >= \frac{1}{d^2} < G_1 > + \frac{1}{\Delta_2} < G_2 >$, where $G_1$ and $G_2$ are the graphs in $S^3$ pictured in Figure 4.

![Figure 4](image3.png)
We expand each one using Figure 5.

\[ <G_1> = (A^2 d + 2) \]

\[ + A^{-2} \]

Figure 5

\(<G_2> \] is easily seen to be \(d^2(A^2 d + 2 + A^{-2}d)\). After we expand \(G_2\) as in Figure 3, we may discard the term with coefficient \(A^{-2}\) using the vanishing of the idempotent \(f^{(2)}\) times a hook. We are left with two simply linked theta curves each with edges one, one and two. We may replace these with loops labelled two. See for instance [KL, page 40]. Thus \(<G_2> \] is \(A^2 d + 2\) times the evaluation of a Hopf link colored two which is \(A^{-16} \sum_{j=0,2,4} A^{j(j+2)}\). This is a special case of a formula in [KL,p127] and is also easily found using [KL,9.15]. Putting this together one calculates that \(<L>\] is indeed the previously calculated trace.
