Abstract

**Background:** Previous studies have shown that a certain proportion of the population did not seek medical treatment after coughing, and understanding the potential reasons is crucial for disease prevention and control.

**Method:** A population-based study was conducted with the probability proportional to population size sampling in Yiwu, Zhejiang, China. A total of 5,855 individuals aged $\geq 15$ years lived in Yiwu, China for more than 6 months were included. All participants completed a pad-based questionnaire to collect detailed information by a face-to-face interview. Characteristics of individuals were described by categories of health seeking behavior using frequency and percentage. Univariate and multivariate logistic regression analyses were performed to estimate the associations of social-demographic and cough characteristics with health seeking behavior.

**Results:** 19.3% (1,129/5,855) of participants had a cough in the past month, 40% (452/1,129) had sought medical treatment. Of these, 26.5% (120/452) chose hospitals at county level or above. Individuals aged $\geq 65$ years old (OR=2.25, 95%CI: 1.23, 4.12), female (OR=1.57, 95%CI: 1.21, 2.06), living in rural areas (OR=1.30, 95%CI: 1.003, 1.69), persistent cough for 3-8 weeks (OR=2.91, 95%CI: 1.72, 4.92) and with more accompanying symptoms ($P_{\text{trend}}<0.001$) were more likely to seek medical treatment, but those coughed for $>8$ weeks were not ($p>0.5$). Female (OR=0.33, 95%CI: 0.21, 0.54) and people living in rural areas (OR=0.57, 95%CI: 0.36, 0.92) were less likely to choose hospitals at county level or above while the higher educated were more likely to (OR=3.29, 95% CI: 1.35, 8.02). Those who coughed for more than 2 weeks were more likely to choose hospitals at or above the county level. But the number of accompanying symptoms does not show any significant relationship with the choice of medical facility.

**Conclusion:** The present study found that age, gender, living areas and features of cough were associated with health seeking behavior. It is worth noting that coughing too long (e.g. $>8$ weeks) instead of seeking medical treatment. Targeted measures should be developed based on the key factors found in this study to guide persons to seek medical treatment more scientifically.

**Background**

Cough is an essential defensive mechanism. It is not only a common symptom of respiratory diseases but also can reflect significant diseases$^{[1,2]}$. More importantly, cough is an important factor in the spread of respiratory infectious diseases$^{[3,4]}$. According to the International Standards for Tuberculosis Care, all persons with otherwise unexplained productive cough lasting 2–3 weeks or more should be evaluated for tuberculosis$^{[5,6]}$. Recent studies also found that pertussis characterized by persistent cough is more prevalent in some areas, with a prevalence of 10.9–24.5%$^{[7-9]}$. In China, the prevalence of cough fluctuates between 9–64%, and the corresponding burden of disease cannot be underestimated$^{[10]}$. Thus scientific health seeking behavior of patients with cough is of great importance, which is conducive to the
early diagnosis and treatment of diseases, especially contribute to the promptly prevention and control of respiratory infectious diseases.

However, previous studies found that a high proportion of patients who did not seek medical treatment after cough, and socio-demographic characteristics were associated with health-seeking decision \[^{11-13}\]. However, most of them were conducted abroad and found that evidence describing the potential risk factors are heterogeneous. A risk factor in one setting may promote the health-seeking decision but not in other settings. For example, a Ethiopia study found that higher income group were more likely to seek medical service\[^{14}\], while studies in South African\[^{12}\] and Zambia\[^{15}\] showed an opposite association for the same risk factor, and study in India\[^{16}\] found there was no correlation between income and health-seeking decision. The same situation occurs in other risk factors, such as age, gender, occupation and smoking status\[^{13, 15, 17-19}\]. Besides, some factors were studied extensively in many studies (namely age, gender, education, occupation and income) while others may only appear in very few studies (namely, features of cough)\[^{13, 20}\]. What’more, there is still no study has focused on the association between the duration of a cough and health seeking behavior.

Besides, studies on the choice of medical facilities for individuals with cough is very limited. In China, only very few studies have conducted at health facility level and focused on the individuals with presumptive tuberculosis\[^{21-23}\].

Here, a community survey provided us with a unique opportunity to look at the health seeking behavior of individuals with cough. The aim of the present study was to describe the health seeking behaviors (including health-seeking decision and choice of medical facility) of individuals with cough, and to examine the associations of social-demographic characteristics and features of cough with health seeking behavior.

**Methods**

**Study population**

All individuals aged \( \geq 15 \) years and were living in Yiwu for more than 6 months were considered as the source population. 50 clusters were selected from 14 town/streets in Yiwu with the probability proportional to population size sampling method, followed by a quota sampling method based on age and sex to select 110 individuals from each cluster. Then well-trained investigators went to each cluster to interview individuals who met the above criteria through simple random sampling.

All individuals completed a pad-based questionnaire to collect detailed information by a face-to-face interview, including socio-demographic characteristics, features of cough and health seeking behaviors. Among them, individuals who have had a cough in the past month were included in the present study.
Measurement

Assessment of health seeking behavior

Based on the availability of data, the present study defined health seeking behavior as health-seeking decision and choice of medical facility. Participants were asked “Did you go to a medical facility for treatment after your last cough?” to acquire their health-seeking decision. If the participants answered “Yes”, they were further asked “which medical facility did you choose”. Options include clinics, 14 township hospitals or community health service centers, municipal hospitals, and others (open answer). We categorized the choice of medical facility into hospitals at county level or above and community health service center or below.

Other covariates

Cough was assessed by asking participants “Have you had a cough during the past month”. If the participants answered “Yes”, they were further asked the cough duration and whether they had accompanying symptoms, such as fever, expectoration, sore throat, runny nose, dyspnea, headache, fatigue, lethargy etc. We categorized the duration of cough period into ≤ 2 weeks, 3-8 weeks and > 8 weeks, and defined ≤ 2 weeks as the reference group. And numbers of accompanying symptoms into 3 groups, namely 0 (reference), 1, 2 and above.

Demographic and socioeconomic characteristics including age (15-24, 25-64, ≥65 years old), gender, living areas (rural or urban), level of education (primary school or below, middle/high school, college or above), occupation(student, unemployment, business and services, professionals, farmers and workers), household income (<100,000, 100,000-199,999 and ≥20,000 yuan per year), children under 5 years old (yes or no), current smoking status (yes or no), and the history of common chronic diseases (yes or no).

Statistical Analysis

Socio-demographic characteristics of participants were described using frequency and percentage. Both univariate and multivariate logistic regression analyses were performed to estimate the associations of social-demographic characteristics and features of cough with health-seeking decision or choice of health facilities. All statistical analyses were conducted using SPSS 19.0 statistical software and all p-values refer to two-tailed tests. Statistical significance was set at P <0.05.

Results

Characteristics of study population
Of 5,855 eligible individuals interviewed, 69.6% of individuals aged 25–64 years old, 10.8% were ≥ 65 years old, 50.7% were females and 40.0% living in rural areas. Around half had attended middle school, 22.7% graduated from college and above. 1,129 (19.3%) reported coughing in the past month. Detailed characteristics of individuals are shown in Table 1.

Factors associated with health-seeking decision

Of the 1,129 participants who reported coughing in the past month, 40% (452) had been to medical facilities. The associations of socio-demographic characteristics and features of cough with health-seeking decision are presented in Table 2. Participants who aged ≥ 65 years old, female and living in rural areas were associated 2.26 (95%CI: 1.24, 4.14), 1.57 (95%CI: 1.21, 2.07) and 1.31 (95%CI: 1.01, 1.70) times greater likelihood of seeking medical treatment respectively. Compared with individuals coughed for ≤ 2 weeks, those coughed for 3–8 weeks was 2.81 (95%CI: 1.68, 4.73) times more likely to seek medical treatment. However, there was no significant difference between those coughed for more than 8 weeks and less than 2 weeks. A significant positive trend (P < 0.001) was observed between the number of accompanying symptoms and health-seeking decision. Compared with participants who reported no accompanying symptoms with cough, those reported symptoms were more likely to seek medical treatment, particularly for those with two symptoms and above (OR = 3.87, 95% CI: 2.74, 5.47).

Factors associated with choice of medical facility

Of the 452 participants who went for medical treatment, 120 (26.5%) chose hospitals at county level or above. The associations of socio-demographic characteristics and features of cough with choice of medical facility are presented in Table 3. Female and people live in rural areas were 0.33 (95%CI: 0.21, 0.54) and 0.57 (95%CI: 0.36, 0.92) times less likely to choose hospitals at county level or above respectively. Individuals with college degree or above were more likely to seek medical treatment in hospitals at or above the county level compared to those with education below primary school (OR = 3.29, 95% CI: 1.35, 8.02). Participants who coughed for 3–8 weeks and > 8 weeks were associated with a higher likelihood of choosing hospitals at or above the county level (OR = 2.35, 95%CI: 1.19, 4.61, OR = 3.13, 95%CI: 1.24, 7.90, respectively). Number of accompanying symptoms does not show significant relationship with choosing medical facility.
Table 1
Socio-demographic characteristics of the total population and individuals with cough in the past month.

| Characteristics          | Total population | Individuals with cough |

**Discussion**

To the best of our knowledge, the present study is the first community-based study focused on the association of socio-demographic and cough characteristics with health seeking behavior in the Chinese population. We found that 19.3% of the respondents reported a cough in the past month, 40% of them had sought medical treatment. Individuals more than 65 years old, female, with cough for 3-8 weeks and with more accompanying symptoms were more likely to seek medical treatment. For those had sought medical treatment, 26.5% of them chose hospitals at county level or above. Male, people live in urban areas, individuals graduated from college and above and with cough for more than 2 weeks were more likely to choose hospitals at county level or above.

**Health-seeking decision**

Contrary to some previous studies on health-seeking behavior\textsuperscript{[12, 14, 15]}, we found that some of the socio-demographic characteristics, such as education, occupation, family size and household income do not seem to be associated with the probability of seeking medical treatment after coughing. Smoking status and history of chronic disease were also not significantly associated with health-seeking decision after adjusting for other factors. These may be related to population selection, and heterogeneity in different countries.

The present study found that individuals aged ≥ 65 years old and living in rural areas were more likely to seek medical treatment. Besides, women were more likely to seek medical treatment than men, which is in parallel with studies conducted in Zambia and Vietnam\textsuperscript{[15, 24]}. This may be explained by the fact that women were more troubled by cough than men\textsuperscript{[25, 26]}. What's more, some studies focusing on gender differences in health-seeking behavior have pointed out that men were more likely to behave masculinity and a healthy state thus less likely to seek care\textsuperscript{[27]}. 
The present study was the first to focus on the association between cough duration and health-seeking decision in China. It is highly worth noting that individuals with cough for 3-8 weeks were more likely to seek medical treatment, while those coughed for > 8 weeks were not. The possible explanation for this phenomenon could be that individuals who have been coughing for >8 weeks were already used to coughing and regard it as a lifestyle habit rather than a disease. However, in addition to common causes of chronic cough, recent studies have found that pertussis has became a prevalent disease in some areas [7, 8], and B. pertussis infection should be considered as a significant pathogenic infection in adult patients presenting a cough of more than 3 weeks duration [28, 29]. And tuberculosis should be evaluated also among persons with unexplained productive cough lasting 2–3 weeks or more[6]. Thus there is no doubt that prolonged coughing without seeking medical treatment timely will bring an increased risk of transmission of such respiratory infectious disease. It is extremely desirable to undertake extensive educational campaigns about cough especially persistent one, so as to encourage individuals to visit medical facilities in time.

What's more, the number of accompanying symptoms showed a clear increasing trend with health-seeking decision, as were observed in India and Tanzania [13, 20]. Previous studies have also indicated that if a cough is not distressing or associated with any other symptoms that restrict one's ability to function/work, people do not usually seek medical care [30, 31]. Because the cough often be regarded as very common symptom and not an illness, whereas cough together with other symptoms, such as fever, expectoration, is more consistently felt to be an illness.

**Choice of medical facility**

In the present study, the multivariate analysis consistently show that individuals living in rural areas and women were less likely to choose hospitals at or above the county level, while the most educated persons were more likely. Studies conducted in Vietnam[24] and China[23, 32] also found that women took more health-care actions than men, but chose less qualified providers (like self-medication, pharmacist, or private practitioner) and individuals living in rural areas had poor access to medical facility. But contrary to previous studies conducted in China [21, 22, 33], the household income was not significant associated with the choice of medical facility after adjusting for other confounders in the present study. This change may be due to a decline in health spending variance as the economy develops, with rising living standards and incomes.

We also found that individuals who coughed for more than 2 weeks were associated with a higher likelihood of choosing hospitals at or above the county level, while number of accompanying symptoms did not show any significant relationship with their choice. This reveals an interesting fact that people were more likely to seek medical treatment when the accompany symptoms of cough appear, but pay more attention to the duration of cough when choosing a hospital. The result echoes a call in a Japanese study [34], which suggested that individuals suffering from cough that does not resolve within a short period of time should be taken seriously regardless of the severity, as cough can be a sign of serious
diseases such as lung cancer, pertussis and pulmonary tuberculosis [2, 35, 36]. Based on the fact, it is recommended to strengthen the training of relevant personnel in such facilities to improve their attention to persistent cough, as well as the level of surveillance and case detection of the above serious diseases.

**Limitations**

Although the data in the present study was based on a community-based population and corrected for established and potential confounding factors (both socio-demographic and cough characteristics), these findings should also be interpreted in light of some limitations. First, it is important to acknowledge the limitations of the subjective perceptions and self-reports and therefore may be biased by potential under-reporting or over-reporting and recall bias, even though we asked for information within the past month to reduce recall bias. Second, due to the limited sample size, some significant positive associations may not be demonstrated in the present study. Finally, the study cannot exclude the effects of residual confounding by unmeasured risk factors, such as medical insurance and cause of cough. Therefore, larger sample size studies with more adjusted confounders are warranted to examine the further association and make a firm complement to the current study.

**Conclusion**

The present study found that only a small proportion of individuals sought medical treatment after cough and of these, about 1/3 chose hospitals at county level or above. Age, gender, living areas, education level as well as features of cough were associated with health seeking behavior. Targeted intervention measures should be formulated based on the above key factors to guide people to seek medical treatment scientifically and rationally.

**Declarations**

**Ethics approval and consent to participate**

The Ethical Review Committee of the Chinese Center for Disease Control and Prevention (Beijing, China) approved the study. All the participants provided written informed consent.

**Consent for publication**

Not applicable.

**Availability of data and materials**

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.
