Angiotensin II (Ang II), a key mediator of hypertensive, causes structural changes in the arteries (vascular remodeling), which involve alterations in cell growth, vascular smooth muscle cell (VSMC) hypertrophy. Ang II promotes fibrotic factor like IGFBP5, which mediates the profibrotic effects of Ang II in the heart and kidney, lung and so on. The purpose of this study was to identify the signaling pathway of IGFBP5 on cell proliferation and migration of Ang II-stimulated VSMC. We have been interested in Ang II-induced IGFBP5 and were curious to determine whether a Pitavastatin would ameliorate the effects. Herein, we investigated the question of whether Ang II induced the levels of IGFBP5 protein followed by proliferation and migration in VSMC. Pretreatment with the specific Angiotensin receptor type 1 (AT1) inhibitor (Losartan), Angiotensin receptor type 2 (AT2) inhibitor (PD123319), MAPK inhibitor (U0126), ERK1/2 inhibitor (PD98059), P38 inhibitor (SB600125) and PI3K inhibitor (LY294002) resulted in significantly inhibited IGFBP5 production, proliferation, and migration in Ang II-stimulated VSMC. In addition, IGFBP5 knockdown resulted in modulation of Ang II induced proliferation and migration via IGFBP5 induction. In addition, Pitavastatin modulated Ang II induced proliferation and migration in VSMC. Taken together, our results indicated that Ang II induces IGFBP5 through AT1, ERK1/2, P38, and P3K signaling pathways, which were inhibited by Pitavastatin. These findings may suggest that Pitavastatin has an effect on vascular disease including hypertension.

Key Words: Hypertension, IGFBP-5, Pitavastatin, Proliferation, VSMC

INTRODUCTION

The insulin-like growth factors (IGFs) are normally bound to insulin-like growth factor binding proteins (IGFBPs) [1]. IGFBPs regulate the actions of IGFs in endocrine, paracrine, and autocrine settings [2]. IGFBPs 1 ~ 6 evolved into high-affinity IGF binders to influence cell growth by both IGF-dependent and IGFBPs 7 ~ 10 into low-affinity IGF binders by IGF-independent mechanisms [2]. IGFBP5, the most conserved IGFBP in all vertebrates [3], is closely related to embryonic development [4], various cancer development [5-9] and differentiation of skeletal muscle [10]. In particular, IGFBP5 is associated with cell proliferation [11], cell survival [11-13] and interaction with extracellular matrix proteins (ECM) [14-16]. In our previous study, IGFBP5 was the only IGFBP5 that was expressed at a higher level in the VSMC from hypertensive compared to those from normotensive rat [17]. Previous studies have shown that IGFBP5 stimulates cell growth in human intestinal smooth muscle by Ras-dependent activation of p38 MAP kinase and extracellular signal-regulated kinase (ERK1/2) pathways [18]. In addition, IGFBP5 plays an important role in regulation of VSMC proliferation via ERK1/2 signaling [17].

Angiotensin II (Ang II), a key mediator of hypertensive, causes structural changes in the arteries vascular remodeling, which involve alterations in cell growth, VSMC hypertrophy, and ECM accumulation [19-21]. The physiological actions of Ang II are induced via its 2 main cell surface receptors; AT1 (type 1 receptor), AT2 (type 2 receptor) [22,23]. AT1 is upregulated in cardiovascular diseases, including atherosclerosis, hypertension, cardiac hypertrophy, and obesity [24].
Ang II induced IGFBP5 effects has not been clearly defined, but also whether IGFBP5 facilitates proliferation and migration. In the current study, we demonstrate that IGFBP5 might play a critical role in modulating the action of Ang II-induced IGFBP5 on VSMC proliferation and migration. Thus, we hypothesize that Pitavastatin may play a significant immunomodulatory effects and reduce vascular injury. Simvastatin prevented the development of hypertension and cardiovascular hypertrophy together with inhibition of the induced Ang II production of ROS. Simvastatin inhibited VSMC proliferation via inactivation of ERK1/2. In previous studies, VSMC from SHR proliferated more rapidly than those from normotensive WKY. In addition, IGFBP5 is endogenously up-regulated in VSMC of hypertensive rats. They showed that IGFBP5 stimulates VSMC proliferation in normotensive rat arteries by activating the ERK1/2 MAPK signaling pathway. We therefore wondered not only whether Ang II induced IGFBP5 but also whether IGFBP5 facilitates proliferation and migration in VSMC. However, the signaling mechanism for Ang II induced IGFBP5 effects has not been clearly defined. In the current study, we demonstrate that IGFBP5 might be upregulated by Ang II, and IGFBP5 expression might contribute to proliferation and migration through ERK1/2, p38, Akt, and Egr1 signaling pathways in VSMC. With this background, we hypothesize that Pitavastatin may play a critical role in modulating the action of Ang II-induced IGFBP5 on VSMC proliferation and migration. Thus, we examined which signaling is involved in Ang II-induced IGFBP5 effects and how Pitavastatin modulates the signaling mechanism of Ang II-induced IGFBP5. Our results indicate that Ang II induced IGFBP5 via ERK1/2, p38, Akt, and Egr1. Pitavastatin modulates Ang II induced IGFBP5 expression, cell proliferation, and migration via IGFBP5.

**METHODS**

**Materials**

Dulbecco’s modified Eagle’s medium (DMEM), fetal bovine serum (FBS), and antibiotics (penicillin and streptomycin) were purchased from Gibco BRL (Rockville, MD, USA). Anti-β-actin, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) were purchased from Sigma-Aldrich (St. Louis, MO, USA). Anti-IGFBP5, anti-JNK, anti-pJNK, anti-p38, anti-pp38, anti-ERK1/2, anti-pERK1/2, anti-Akt, goat anti-rabbit IgG, goat anti-mouse IgG, donkey anti-goat IgG, enhanced chemiluminescence (ECL), IGFBP5, Egr1, and control siRNA were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, USA). Ang II, PD98059, U0126, SP600125, SB203580, and LY294002 were purchased from Calbiochem (San Diego, CA, USA). ERK1/2 and control siRNA were purchased from Thermo Scientific Dharmacon (Chicago, IL, USA). Lipofectamine2000™ was purchased from Invitrogen (Carlsbad, CA, USA), recombinant IGFBP5 was purchased from R&D system (Minneapolis, MN, USA).

**Cell Culture**

A7r5 smooth muscle cells were purchased from the American Type Culture Collection (Manassas, VA, USA) and maintained under 5% CO2 at 37°C in Dulbecco’s modified Eagle’s medium with 1-glutamine and 4,500 mg/L glucose containing 10% fetal bovine serum (Invitrogen, Carlsbad, CA, USA). They were sub-cultured every 3 or 4 days with trypsin (0.25%) and EDTA (0.02%). A portion of the detached cells were transferred to normal Tyrode’s (NT) solution and kept at 4°C in micro-tubes.

**Western blot analysis**

Whole cell extracts were prepared by lysing cells in RIPA buffer protein extraction solution. Protein concentrations were quantified with protein assay reagent (Bio-Rad, Hercules, CA, USA). Equal amounts of protein were mixed with sodium dodecyl sulfate (SDS) sample buffer and incubated for 5 min at 100°C before loading. Total protein samples (30 μg) were subjected to SDS-polyacrylamide gel electrophoresis (SDS-PAGE) for 1 hr and 30 min at 100 V. The separated proteins were then transferred onto PVDF membranes for 1 hr at 30 mA using a SD Semi-dry Transfer Cell. The membranes were blocked with 5% non-fat milk in PBS-T (phosphate buffered saline containing 0.05% Tween 20) for 1 hr at room temperature, followed by incubation with the primary antibodies at a dilution of 1:1,000 in 5% skim milk in PBS (phosphate buffered saline) overnight at 4°C. The membranes were then washed with PBS-T, followed by incubation with the secondary antibodies in 5% skim milk in PBS for 1 hr at room temperature. Finally, after rinses with the wash buffer, the membranes were exposed to ECL western blot analysis detection reagents (MicroChemi 4.2 Chemilumineszenz-System, Israel).

**Cell proliferation assay**

Cell numbers were determined after 24 or 48 hours of stimulation with 10% FBS using a hemocytometer, and cell viability was determined using the MTT assay. VSMC were seeded onto 24-well plates at a density of 1x10^4 cells per well in DMEM supplemented with 10% FBS. After different treatments, 50 μl of 1 mg/ml MTT solution was added to each well (0.1 mg/ml), followed by incubation for 4 hrs. The supernatants were then aspirated, and the formazan crystals were solubilized with 200 μl of dimethyl sulfoxide (DMSO). The supernatants (100 μl) of these solutions were placed in the wells of 96-well plates. Cell proliferation was determined using a microplate reader (Bio-Rad, Hercules, CA, USA) measuring absorbance at 570 nm.

**Migration assay**

Cell migration was analyzed by a scratch wound assay. Cells were grown to confluence in 6-well plates. A scratch
Pitavastatin Inhibits IGFBP-5 in VSMC

**RESULTS**

**IGFBP5 expression is induced by Ang II in VSMC**

IGFBP5 is upregulated in both VSMC of hypertensive rats and Ang II-stimulated VSMC [18]. To determine whether Ang II induces IGFBP5 protein level in VSMC, cells were treated with Ang II 0, 0.1, 0.5, 1.0 μM respectively for 24 hrs. Ang II increased IGFBP5 expression in a dose-dependent manner. IGFBP5 expression peaked at 0.5 μM Ang II. The special expression of IGFBP5 at 0.5 μM showed an approximate 2.5 fold increase over the control (p<0.05) (Fig. 1A). Cells were treated with 0.5 μM Ang II at various times, 0, 1, 3, 6, 12, and 24 hrs. Ang II increased IGFBP5 expression in a time-dependent manner. IGFBP5 expression showed a dramatic increase at 12 hrs (Fig. 1B). These results suggest that Ang II induces IGFBP5 in time- and dose-dependent manner in VSMC.

**Pitavastatin reduces induction of pERK1/2, p38, pAkt, and Egr1 expression by Ang II in VSMC**

Upregulation of Ang II has been shown to activate signaling cascades that activate MAPKs (ERK1/2, JNK, p38), Akt, and Egr1 [26,29,32]. We demonstrate activation of MAPKs, Akt and Egr1 by Ang II. Ang II induced p-ERK1/2, p-P38, p-JNK, p-Akt, and Egr1 after 10 min with 0.5 μM Ang II stimulation. p-MAPKs and p-Akt peaked after 15 min and Egr1 peaked after 30 min (Fig. 2A). To evaluate the effect of Pitavastatin on Ang II induced MAPKs, Akt and Egr1 activation, cells were treated with Pitavastatin 0.5 μM and 1.0 μM, respectively. Pitavastatin (1.0 μM) inhibited Ang II induced activation of ERK1/2, p38, Akt, and Egr1 in VSMC. However JNK was not induced by Ang II in VSMC (Fig. 2B). In addition, we confirmed that Pitavastatin had no inhibition effect on Ang II-activated AT1R (data not shown). Knockdown of ERK1/2 resulted in complete inhibition of Ang II induced IGFBP5 expression in VSMC (Fig. 2C). Knock down with Egr1 resulted in complete inhibition of Ang II induced expression of IGFBP5 in VSMC (Fig. 2D). These results suggest that Pitavastatin modulates Ang II-induced ERK1/2, p38, (but not JNK), PI3K, and Egr1.

**Ang II induces VSMC proliferation via AT1-dependent IGFBP5 induction**

In our previous figure, we confirmed that Ang II induced IGFBP5 in VSMC. However, whether AT1 or AT2 receptors activate IGFBP5 has not been clearly defined. Therefore we first examined whether AT1 or AT2 receptors activate IGFBP5. Ang II-induced IGFBP5 expression was blocked by AT1R antagonist, Losartan, but not AT2R antagonist,
Pitavastatin reduced phosphorylation of MAPK and expression of Egr1 induced in Ang II-stimulated A7r5. Cells were treated with Ang II 0.5 μM. VSMC were incubated with Ang II for 0, 5, 10, 15, 30, 60, 90 min respectively (A). Cells were treated with Pitavastatin for 30 min before Ang II 0.5 μM for 15 min (B). p-JNK, p-ERK1/2, p-p38, p-Akt and Egr1 were determined by western blot analysis. Cells were transfected with ERK1/2 siRNA and then treated with Ang II 0.5 μM for 12 hrs (C). Cells were transfected with Egr1 siRNA and then treated with Ang II 0.5 μM for 12 hours (D). After treatment, IGFBP5 protein expression was measured by Western blot. These data are representative of three experiments.

Ang II-induced IGFBP5 expression through ERK1/2, p38, and Akt

In the previous study, Ang II activated ERK1/2, p38 and JNK, PI3K and Egr1 (Fig. 2). We investigated which signaling was involved in Ang II-induced IGFBP5 in VSMC. We first confirmed whether Ang II-induced IGFBP5 is induced by ERK1/2. We treated with MEK/ERK1/2 inhibitors such as U0126 (1 μM), PD98059 (1 μM) for 45 min, followed by treatment with Ang II for 12 hrs in VSMC. Next, we investigated whether Ang II-induced IGFBP5 is induced by p38, JNK, and PI3K. We treated VSMC with p38 inhibitor; SB203580 (10 μM), JNK inhibitor; SP600125 (25 μM) and PD123319 (Fig. 3A). In addition, Losartan inhibited Ang II-induced cell proliferation in VSMC (Fig. 3B). Then knockdown of AT1R resulted in significantly inhibited Ang II-induced expression of IGFBP5 in VSMC. IGFBP5 recombinant protein reversed inhibition of IGFBP5 expression by AT1R siRNA in VSMC (Fig. 3C). In addition, knockdown with AT1R resulted in significantly inhibited Ang II-induced cell proliferation. IGFBP5 recombinant reversed inhibition of Ang II-induced VSMC cell proliferation by AT1 siRNA (Fig. 3D). Together, these findings suggest that Ang II activates IGFBP5 via AT1 receptor and Ang II induced VSMC proliferation via induction of IGFBP5.
Pitavastatin Inhibits IGFBP-5 in VSMC

Fig. 4. Effects of inhibiting MAPKs on Ang II-induced IGFBP5 expression in VSMC. Cells were pretreated with U0126 (1 μM) and PD98059 (1 μM) for 1 hr and then incubated with Ang II 0.5 μM for 12 hrs. Protein level was determined by western blot (A). Cells were pretreated with SB203580 (10 μM), SP600125 (25 μM), and LY294002 (10 μM) for 1 hr and then incubated with Ang II 0.5 μM for 12 hrs. Protein level was determined by western blot (B, C). Cells were pretreated with U0126, PD98059, SB203580, SP600125, and LY294002 for 1 hr and then incubated with Ang II 0.5 μM for 24 hrs. Cell proliferation was determined by MTT assay (D). These data are representative of three experiments. *p < 0.001 compared with untreated cells, #p < 0.001 compared with Ang II.

PI3K inhibitor, LY294002 (10 μM) for 45 min, followed by treatment with Ang II for 12 hrs. IGFBP5 was inhibited by the MEK1/2 inhibitors in Ang II treated VSMC (Fig. 4A). And also IGFBP5 expression was significantly inhibited by the p38 inhibitor and PI3K inhibitor in Ang II treated VSMC. However, treatment with JNK inhibitor had no inhibitory effect in Ang II treated VSMC (Fig. 4B and 4C). In addition, Ang II-induced cell proliferation was inhibited by the MEK1/2, p38 and PI3K inhibitors not JNK inhibitor in VSMC (Fig. 4D). These results demonstrate that Ang II induced IGFBP5 and cell proliferation via ERK1/2, p38, and PI3K signaling in VSMC.

Fig. 5. Effects of IGFBP5 on Ang II-induced proliferation and migration in VSMC. Cells were transfected with IGFBP5 siRNA and then treated with Ang II 0.5 μM for 12 hrs. IGFBP5 protein expression was measured by western blot (A). Cells were treated with Ang II 0.5 μM for 24 hrs. Cell proliferation was measured by MTT assay (B). Cell migration was measured by scratch wound assay (C, D). These data are representative of three experiments. *p < 0.001 compared with untreated cells, #p < 0.001 compared with Ang II.

IGFBP5 knockdown modulates Ang II-induced proliferation and migration

To determine whether the IGFBP5 expression is due to Ang II stimulation, cells were transfected with IGFBP5 siRNA. Knockdown of IGFBP5 suppressed IGFBP5 expression (Fig. 5A). Knockdown of IGFBP5 resulted in inhibition of Ang II-induced cell proliferation in VSMC (Fig. 5B). Knockdown of IGFBP5 resulted in suppression of Ang II-induced cell migration in VSMC (Fig. 5C). Migration was estimated by measuring the cell area within the wound re-
Pitavastatin modulates Ang II-induced IGFBP5 expression, proliferation and migration in VSMC via IGFBP5 expression. Cells were pretreated with Pitavastatin 1.0 μM for 1 hr and then incubated with Ang II 0.5 μM for 12 hrs. IGFBP5 protein expression was measured by western blot (A). And cells were treated with Ang II 0.5 μM for 24 hrs. Cell proliferation was measured by MTT assay (B). Cell migration was measured by scratch wound assay (C, D). These data are representative of three experiments. *p < 0.001 compared with untreated cells, #p < 0.001 compared with Ang II, $p < 0.005 compared with untreated cells.

Angiotensin II (Ang II) plays a fundamental role in controlling blood pressure and tissue remodeling. Some studies have shown that Ang II plays critical roles in cell proliferation and angiogenesis of various tumors [19-21]. VSMC proliferation contributes to the arterial remodeling associated with hypertension and atherosclerosis [20]. Atherosclerosis progression is closely correlated with VSMC proliferation and migration, which requires a coordinative rearrangement of the VSMC. Ang II leads to AT1R activation, which has been shown to activate signaling cascades that activate MAPKs, including ERK1/2, JNK, and p38, which are implicated in VSMC differentiation, proliferation, migration, and fibrosis [22,23,25,26]. In addition, upregulation of Egr-1 was recently shown to be a key contributing factor in stimuli-induced VSMC proliferation [27,28]. Furthermore, Ang II stimulates Akt/PKB activity via AT1 receptors in VSMC [32]. AT1 is upregulated in cardiovascular diseases including atherosclerosis [24]. We confirmed that AT1R are proposed to be Ang II responsive mediators that can cause IGFBP5 expression, leading to cell proliferation. As shown in Fig. 3, Ang II-induced IGFBP5 expression was blocked by AT1R antagonist, Losartan, but not AT2R antagonist, PD123319 (Fig. 3A). In addition, Losartan inhibited Ang II-induced cell proliferation in VSMC (Fig. 3B). Then knockdown with AT1R resulted in significantly inhibited Ang II-induced cell proliferation and IGFBP5 recombinant reversed inhibition of Ang II-induced VSMC cell proliferation by AT1 siRNA (Fig. 3D). Ang II activates IGFBP5 via AT1 receptor results in VSMC proliferation.

Several studies have reported that IGFBP5 promotes proliferation and migration in VSMC [11-16,39]. IGFBP5 also plays a role in modulation of VSMC proliferation in hypertensive rats via ERK1/2 MAPK signaling [18]. We hypothesize that modulation of Ang II-induced IGFBP5 effects may play an important inhibitory role in cardiovascular diseases including atherosclerosis. We confirmed that IGFBP5 is inhibited by the MEK1/2 inhibitors in Ang II treated VSMC (Fig. 4A). And also IGFBP5 expression was significantly inhibited by the p38 inhibitor and PI3K inhibitor in Ang II treated VSMC. However, treatment with JNK in-
Pitavastatin Inhibits IGFBP-5 in VSMC

hibitor had no inhibitory effect in Ang II treated VSMC (Fig. 4B and 4C). In addition, Ang II-induced cell proliferation was inhibited by the MEK1/2, p38 and PI3K inhibitors and PI3K inhibits not JNK inhibitor in VSMC (Fig. 4D). Our results not only confirm that Ang II induced IGFBP5 expression via multiple signaling kinases, but also provide evidence indicating that Ang II-induced IGFBP5 promoted cell proliferation and migration in VSMC. Our results provide new insights into the mechanism underlying Ang II-induced IGFBP5 effects, such as migration and proliferation (Fig. 5).

In several studies, Statins have significant immunomodulatory effects and reduce vascular injury as 3-hydroxy-3-methylglutaryl-CoA reductase inhibitors [34]. In the current study, Pitavastatin inhibited Ang II-induced proliferation by inactivating ERK1/2 in VSMC [36]. As one of our important objectives, we examined whether Pitavastatin modulates Ang II induced IGFBP5 expression, proliferation, and migration in VSMC. Our results demonstrated that Pitavastatin inhibits activation of ERK1/2, P38, PI3K, and Egr1 by Ang II. This is the first study to report that Pitavastatin has a modulatory effect on Ang II-induced IGFBP5 in VSMC. A previous study showed that Statins have significant immunomodulatory effects and reduce cell proliferation [34]. Therefore, we wondered whether Pitavastatin can inhibit Ang II-induced proliferation and migration in VSMC via IGFBP5. As shown in Figure 6, Pitavastatin significantly inhibited Ang II-induced cell proliferation and migration in VSMC. In particular, IGFBP5 recombinant reversed modulation of Ang II-induced VSMC proliferation and migration by Pitavastatin. Pitavastatin modulated Ang II-induced proliferation and migration in VSMC via IGFBP5 expression.

In summary, these findings suggested that Pitavastatin inhibited Ang II-induced expression of IGFBP5 through ERK1/2, p38, and PI3K signaling pathways. IGFBP5 induces VSMC proliferation and migration, which contributes to the progression of atherosclerosis. Taken together, our findings provide evidence that Pitavastatin may play a critical role in Ang II-induced IGFBP5 mediated VSMC formation.
