SHARP BOUNDS FOR EIGENVALUES AND
MULTIPLICITIES ON SURFACES OF REVOLUTION

MARTIN ENGMAN

Abstract. For surfaces of revolution diffeomorphic to $S^2$, it is proved
that $(S^2, can)$ provides sharp upper bounds for the multiplicities of all
of the distinct eigenvalues. We also find sharp upper bounds for all the
distinct eigenvalues and show that an infinite sequence of these eigen-
values are bounded above by those of $(S^2, can)$. An example of such
bounds for a metric with some negative curvature is presented.

1. Introduction

Upper bounds for the multiplicities of eigenvalues have been found by
Cheng and Besson in [5] and [2], respectively. Besson obtained the upper
bound $m_k(g) \leq 4p + 2k + 1$ for the multiplicity of the $k$th eigenvalue of any
compact Riemannian surface of genus $p$. Since these multiplicity bounds are
for eigenvalues which are not necessarily distinct, even the bound $m_k(g) \leq
2k + 1$ for $p = 0$ fails to be sharp after $k = 1$. If, for $p = 0$, one could obtain
the same formula, but for the distinct eigenvalues, then the bound would
be sharp since the multiplicity of the $k$th distinct eigenvalue on $(S^2, can)$
is $2k + 1$. However, without additional restrictions on the metric $g$, this
problem seems to be quite difficult. We will restrict our attention to surface
of revolution metrics in order to obtain a special case of this result via
the methods of the author’s previous article [9]. Although one might still
hope to obtain such a result for arbitrary metrics on $S^2$, there can be no
generalization to higher dimensional spheres because of the results of [1] and
[11].

Another problem of considerable interest is that of bounding the eigen-
values themselves. Cheng (5) obtained upper bounds and later, Li and
Yau (10) obtained both upper and lower bounds in a very general setting.
Again, these bounds are for the sequence of eigenvalues counted with their
multiplicities and, therefore, may not be sharp. In this paper we obtain, for
the special case of surfaces of revolution diffeomorphic to $S^2$, sharp upper
bounds for the distinct eigenvalues. It is also shown that the upper bounds
are achieved only for the constant curvature metric. In general, these upper
bounds are not, themselves, bounded by the eigenvalues of $(S^2, can)$. But

1991 Mathematics Subject Classification. Primary 58G25, 58G30, 53C20; Secondary
35P15.
it is shown that there exists an infinite subsequence of distinct eigenvalues which are bounded by the corresponding eigenvalues of $(S^2, \text{can})$.

The paper concludes with an example of a metric with some negative curvature whose spectrum is strictly less than that of the standard sphere and, in fact, diverges from that of the standard sphere.

2. Previous Results

In this section we present, without proof, those results from [9] which are necessary for our purposes here.

Let $(M, g)$ be a surface of revolution of area $4\pi$ which is diffeomorphic to the sphere. In [8] it was shown that on a certain chart the metric can take the form:

$$g = \frac{1}{f(x)} dx \otimes dx + f(x)d\theta \otimes d\theta$$

where $(x, \theta) \in (-1, 1) \times [0, 2\pi)$ and $f(x) \in C^\infty(-1, 1) \cap C^0[-1, 1]$ satisfies the following conditions:

1. $f(x) > 0 \ \forall x \in (-1, 1)$, $f(1) = f(-1) = 0$ and, $f'(1) = -f'(-1) = 2$.

This metric has Gauss curvature given by $K(x) = \frac{-1}{2f(x)}$. The canonical (i.e. constant curvature) metric is obtained by taking $f(x) = 1 - x^2$ and the metric in this case is denoted by $\text{can}$.

Let $\Delta$ denote the Laplacian on $(M, g)$ and let $\lambda$ be any eigenvalue of $-\Delta$. We use the symbols $E_\lambda$ and $\dim E_\lambda$ to mean the eigenspace for $\lambda$ and its multiplicity, respectively. In this paper $\lambda_m$ will always mean the $m$th distinct eigenvalue. Since $S^1$ (parameterized here by $0 \leq \theta < 2\pi$) acts on $(M, g)$ by isometries, the orthogonal decomposition of $E_\lambda$ has the special form:

$$E_\lambda = \begin{cases} \bigoplus_{j=1}^l (e^{-ik_j \theta} V_{k_j} \oplus e^{ik_j \theta} V_{k_j}) & \text{if } \dim E_\lambda \text{ is even} \\ \bigoplus_{j=1}^l (e^{-ik_j \theta} V_{k_j} \oplus e^{ik_j \theta} V_{k_j}) \oplus V_0 & \text{if } \dim E_\lambda \text{ is odd} \end{cases}$$

where $k_j \in \mathbb{N}$ and $V_{k_j}$ is the one dimensional eigenspace of the ordinary differential operator

$$L_{k_j} = -\frac{d}{dx} \left(f(x) \frac{d}{dx}\right) + \frac{k_j^2}{f(x)}.$$ 

acting on functions which vanish at 1 and -1. Consequently, the spectrum of $-\Delta$ can be studied via the spectra $\text{Spec} L_k = \{\lambda_k^1 < \lambda_k^2 < \cdots < \lambda_k^j < \cdots \}$ for all $k \in \mathbb{Z}$. When $k = 0$ the spectrum is called $S^1$ invariant, otherwise it is called $k$-equivariant. Each $L_k$ has a Green’s operator, $\Gamma_k$, whose spectrum is, of course, $\{1/\lambda_k^j\}_{j=1}^\infty$ and whose trace is given by $\text{tr} \Gamma_k = \sum 1/\lambda_k^1$. Recall that for any constant curvature metric, $\text{can}$, on $S^2$, $\dim E_{\lambda_m(\text{can})} = 2m + 1$.

**Proposition 2.1** (See [9]). The following hold on any $(M, g)$ where $g$ is a surface of revolution metric of area $4\pi$, and $M$ is diffeomorphic to $S^2$.
i: $\text{Spec}(-\Delta) = \bigcup_{k \in \mathbb{Z}} \{\text{Spec}L_k\}$.

ii: If $0 < k < l$ then $\lambda_k^1 < \lambda_l^1$. (Monotonicity)

iii: $tr\Gamma_k = \frac{1}{|k|}$, for $k \neq 0$. (Trace Formula)

iv: Let $\lambda_m$ be the $m$th distinct eigenvalue of $-\Delta$. Then $\dim E_{\lambda_m} = 2m+1$ for all $m$ if and only if $(M, g)$ is isometric to a sphere of constant curvature.

v: If $h$ and $h^2$ are both eigenfunctions of $-\Delta$, then the metric is of constant curvature $\equiv 1$.

Remarks. 1. The explicit form of the trace formula is:

$$\sum_{j=0}^{\infty} \frac{1}{\lambda_k^{j+1}} = \frac{1}{|k|}. \quad (5)$$

This formula is the main ingredient in the proof of iv and will play an important role in what follows.

2. Item iv is one of the main results of [9]. Since its publication, S.Y. Cheng has made some progress toward a more general result. He has proved that any metric on $S^2$ with $\dim E_{\lambda_m} = 2m+1$ is a Z"oll metric.

3. Sharp Bounds for the Multiplicities

Before presenting the main theorems we prove a lemma which shows the relationship between the distinct eigenvalues of $-\Delta$ and those of the operators $L_k$.

**Lemma 3.1.** We will assume the same hypotheses as Proposition 2.1. For all $k \geq 1$ and $j \geq 0$, $\lambda_{k+j} \leq \lambda_k^{j+1}$.

**Proof.** Because of Proposition 2.1, i., ii., and the simplicity of the spectrum of $L_k$, there is a strictly increasing subsequence of eigenvalues of $-\Delta$, $\lambda_1^1 < \lambda_2^1 < \cdots < \lambda_k^1 < \lambda_k^2 < \cdots < \lambda_k^{j+1}$. As there are $(k+j)$ distinct eigenvalues in this list, we must have that $\lambda_k^{j+1}$ is at least the $(k+j)$th distinct eigenvalue of $-\Delta$. In other words, $\lambda_{k+j} \leq \lambda_k^{j+1}$.

And now the multiplicity result can be proved.

**Theorem 3.1.** Let $(M, g)$ be a surface of revolution which is diffeomorphic to $S^2$ and let $\lambda_m$ be the $m$th distinct eigenvalue of $-\Delta$. Then $\dim E_{\lambda_m} \leq 2m+1$ for all $m$, and equality holds for all $m$ if and only if $(M, g)$ is isometric to a sphere of constant curvature.

**Proof.** The second part of the theorem is just Proposition 2.1, iv. above. So we need only prove $\dim E_{\lambda_m} \leq 2m+1$ for all $m$.

If $m = 0$ then $\lambda_0 = 0$ and $\dim E_{\lambda_0} = \dim H^0(M, \mathbb{R}) = 1$ by Hodge theory. So we may assume, henceforth, that $m > 0$. From Lemma 3.1 with $j = 0$, we have:

$$\lambda_m \leq \lambda_m^1 \quad (\forall m). \quad (6)$$
Using Proposition 2.1, we see that $\lambda_m \in SpecL_k$ for some $k \in \mathbb{Z}$, and hence for some $k \geq 0$, due to the symmetry exhibited by equation (3). Finding $\dim E_{\lambda_m}$ is just a matter of counting the summands in equation (3). This is done in the following manner. Define $l_m = \text{card} \{ k \in \mathbb{N} | \lambda_m \in SpecL_k \}$.

Then:

$$
\dim E_{\lambda_m} = \begin{cases} 
2l_m & \text{if } \lambda_m \notin SpecL_0 \\
2l_m + 1 & \text{if } \lambda_m \in SpecL_0 
\end{cases}
$$

So that

$$
\dim E_{\lambda_m} \leq 2l_m + 1. \tag{7}
$$

We can now prove the inequality by contradiction. Suppose, for some $m > 0$, that $\dim E_{\lambda_m} > 2m + 1$. Then from (7), $2m + 1 < 2l_m + 1$ i.e. $m < l_m$. In other words, there are more than $m$ distinct natural numbers in the set $\{ k \in \mathbb{N} | \lambda_m \in SpecL_k \}$. Hence, there exists an element of this set, say $k^*$, which satisfies $m < k^*$ while at the same time $\lambda_m \in SpecL_{k^*}$. To summarize: $\lambda_m \leq \lambda^1_m$ by (6), $\lambda^1_m < \lambda^1_{k^*}$ because of Proposition 2.1 ii, and $\lambda^1_{k^*} \leq \lambda_m$ because $\lambda_m \in SpecL_{k^*}$ and $\lambda^1_{k^*}$ is the first eigenvalue of $L_{k^*}$. Putting these three inequalities together produces the contradiction $\lambda_m < \lambda_m$, and the proof is finished. $\square$

4. Sharp Bounds for the Eigenvalues

In the case of Surfaces of Revolution diffeomorphic to $S^2$, sharp upper bounds for the distinct eigenvalues can be found.

**Theorem 4.1.** Let $(M, g)$ be a surface of revolution which is diffeomorphic to $S^2$ and whose metric is given by (1) and (2). Let $\lambda_m$ be the $m$th distinct eigenvalue of $-\Delta$, then

$$
\lambda_m \leq m^2 \left[ \frac{\int_{-1}^{1} f^{m-1}(x) dx}{\int_{-1}^{1} f^m(x) dx} \right] + m \frac{\int_{-1}^{1} f^m(x) K(x) dx}{2 \int_{-1}^{1} f^m(x) dx} \tag{8}
$$

and equality holds for all $m$ if and only if $(M, g)$ is isometric with $(S^2, can)$.

**Proof.** From Lemma 3.1 with $j = 0$, $\lambda_m \leq \lambda^1_m \forall m$. Since $\lambda^1_m$ is the first eigenvalue of the operator (1), the minimum principle shows that

$$
\lambda_m \leq \frac{\int_{-1}^{1} \left[ f(x) \left( \frac{du}{dx} \right)^2 + \frac{m^2}{f(x)} u^2 \right] dx}{\int_{-1}^{1} u^2 dx}
$$

$\forall u \in C^\infty(-1, 1)$ such that $u(-1) = u(1) = 0$. Setting $u = f^{l/2}(x)$, integrating by parts, and using the fact that $K(x) = (-1/2)f''(x)$ yields

$$
\lambda_m \leq m^2 \left[ \frac{\int_{-1}^{1} f^{l-1}(x) dx}{\int_{-1}^{1} f^l(x) dx} \right] + l \frac{\int_{-1}^{1} f^l(x) K(x) dx}{2 \int_{-1}^{1} f^l(x) dx} \forall l \in \mathbb{N}. \tag{9}
$$
The inequality (8) follows immediately by setting \( l = m \) in this formula.

If \((M, g)\) is isometric with \((S^2, \text{can})\) then \( f(x) = 1 - x^2 \) and \( K(x) \equiv 1 \) and a simple calculation shows that

\[
\frac{\int_{-1}^{1} (1 - x^2)^{m-1} \, dx}{\int_{-1}^{1} (1 - x^2)^m \, dx} = 1 + \frac{1}{2m}.
\]

so that \( \lambda_m \leq m^2 + m \). But these upper bounds are the eigenvalues for \((S^2, \text{can})\).

Conversely, if equality holds in formula (8) for all \( m \), then \( f^{m/2}(x) \) is an eigenfunction with eigenvalue \( \lambda_m \) and \( f^m(x) \) is an eigenfunction with eigenvalue \( \lambda_{2m} \) so by Proposition 2.1 iv., \((M, g)\) is isometric to \((S^2, \text{can})\).

The following theorem produces explicit sharp upper bounds for a subsequence of the distinct eigenvalues.

**Theorem 4.2.** Let \((M, g)\) be a surface of revolution of area \( 4\pi \) which is diffeomorphic to \( S^2 \), and let \( \lambda_m \) be the \( m \)th distinct eigenvalue of \(-\Delta\). For every \( k \in \mathbb{N} \) there exists an \( m \geq k \) such that

\[
\lambda_m \leq m^2 + m.
\]

(i.e. there exists a subsequence, \( \{m_k\}_{k=1}^{\infty} \subset \mathbb{N} \), such that \( \lambda_{m_k}(g) \leq \lambda_{m_k}(\text{can}) \)).

**Proof.** We will show that for every \( k \in \mathbb{N} \), there exists \( j_k \geq 0 \) such that

\[
\lambda^{j_k+1}_k \leq (k + j_k)^2 + (k + j_k),
\]

then, by lemma 3.1, since \( \lambda_{k+j_k} \leq \lambda^{j_k+1}_k \), the theorem follows by letting \( m = k + j_k \).

To prove (10) we assume the contrary: that for some \( k_0 \),

\[
\lambda^{j+1}_{k_0} > (k_0 + j)^2 + (k_0 + j)
\]

for all \( j \geq 0 \). This means that for all \( j \),

\[
\frac{1}{\lambda^{j+1}_{k_0}} < \frac{1}{(k_0 + j)^2 + (k_0 + j)}
\]

and hence, by the trace formula (5)

\[
\frac{1}{k_0} = \sum_{j=0}^{\infty} \frac{1}{\lambda^{j+1}_{k_0}} < \sum_{j=0}^{\infty} \frac{1}{[(k_0 + j)^2 + (k_0 + j)]} = \frac{1}{k_0},
\]

producing the contradiction, \( \frac{1}{k_0} < \frac{1}{k_0} \).

**Remarks.** We suspect that Proposition 2.1, iv., Theorem 3.1, and Theorem 4.2 hold for all metrics on \( S^2 \). Some justification for this belief can be found in the contrapositive statements of these results.

If there exists a Riemannian manifold \((M, g)\), diffeomorphic to \( S^2 \), which satisfies any one of the conditions

i: \( \dim E_{\lambda_m} = 2m + 1 \ \forall m \) but \( \lambda_m(g) \neq \lambda_m(\text{can}) \) for some \( m \),

ii: \( \dim E_{\lambda_m} > 2m + 1 \) for some \( m \),

iii: \( \lambda_m(g) \leq \lambda_m(\text{can}) \) for only a finite number of eigenvalues,
then the group of isometries, $\mathcal{G}(M, g)$, is finite.

In item ii. $m \neq 1$ because, as mentioned in the introduction, Cheng [5] has proved $\dim E_{\lambda_1} \leq 3$ for all Riemannian surfaces which are homeomorphic to $S^2$. Generically, one would not expect to find metrics satisfying any of these conditions. There are examples of metrics with “large” multiplicities, but these examples occur in higher dimensions ([1], [8], and [11]) or for surfaces of larger genus ([4], [7]).

5. Examples

Although one would expect the best estimates to come from the inequality (8), the inequality (9) with $l = 1$ provides rough upper bounds for all the eigenvalues which are much easier to compute and still quite useful. They are:

$$(11) \quad \lambda_m \leq m^2 \left( \frac{2}{\int_{-1}^{1} f(x)dx} \right) + \frac{\int_{-1}^{1} f(x)K(x)dx}{2 \int_{-1}^{1} f(x)dx}.$$ 

The form of the coefficient of $m^2$ suggests that one might distinguish between the two cases $\int_{-1}^{1} f(x)dx < 2$ and $\int_{-1}^{1} f(x)dx \geq 2$. In the former case it is easy to see that these rough bounds exceed the eigenvalues of the standard sphere and so provide little new information about the nature of eigenvalues. The second case is more interesting as we can see from the following:

**Proposition 5.1.** Let $(M, g)$ be a surface of revolution which is diffeomorphic to $S^2$ and whose metric is given by (1) and (2), and let $\lambda_m$ be the $m$th distinct eigenvalue of $-\Delta$. If $\int_{-1}^{1} f(x)dx \geq 2$ then $K(p) < 0$ for some $p \in M$ and

$$(12) \quad \lambda_m \leq m^2 + \frac{\int_{-1}^{1} f(x)K(x)dx}{2 \int_{-1}^{1} f(x)dx}.$$ 

Consequently,

$$\lambda_m(g) < \lambda_m(\text{can})$$ 

for $m$ sufficiently large,

and

$$\lim_{m \to \infty} (\lambda_m(\text{can}) - \lambda_m(g)) = \infty.$$ 

**Proof.** Integrating $\int_{-1}^{1} f(x)dx$ by parts twice leads to the identity:

$$\int_{-1}^{1} f(x)dx = 2 - \int_{-1}^{1} x^2K(x)dx.$$ 

So if $\int_{-1}^{1} f(x)dx \geq 2$ then $\int_{-1}^{1} x^2K(x)dx \leq 0$ and hence $K(x_0) < 0$ for some $x_0 \in [-1, 1]$.

The inequalities and the limit formula follow immediately from (11).
Although these methods do not prove it Proposition 5.1 suggests that metrics on $S^2$ whose curvature has variable sign have spectra which diverge away from that of the standard sphere.

It is easy to find examples for which all of the eigenvalues are less than, and diverging from, those of the standard sphere.

**Example.** The function $f(x) = \frac{2(1-x^2)}{1+x^2}$ satisfies the conditions (2) and so defines a surface of revolution metric on $S^2$ of area $4\pi$. It is an elementary exercise to verify that

$$\int_{-1}^{1} f(x) dx = 2\pi - 4,$$

(13)

$$K(x) = 4 \frac{1 - 3x^2}{(1 + x^2)^3} \text{ and }$$

$$\int_{-1}^{1} f(x)K(x)dx = \pi + \frac{4}{3}.$$

From (13) we see that this metric has negative curvature on the polar regions defined by the union of intervals $(-1, -1/\sqrt{3}) \cup (1/\sqrt{3}, 1)$ and from (11) we have

$$\lambda_m \leq \frac{1}{\pi - 2}m^2 + \frac{3\pi + 4}{12\pi - 24}.$$

As a result

$$\lambda_m < m^2 + 1, \forall m.$$
