Abstract. We report on a lattice investigation of heavy meson interactions and of tetraquark candidates with two very heavy quarks. These two quarks are treated in the static limit, while the other two are up, down, strange or charm quarks of finite mass. Various isospin, spin and parity quantum numbers are considered.

1. Introduction
We study the potential of two static quarks in the presence of two quarks of finite mass. While in \cite{1, 2, 3} we have exclusively considered two static antiquarks and two light quarks ($\bar{Q}Qll$), where $l \in \{u,d\}$, here we also use $s$ and $c$ quarks, i.e. investigate $\bar{Q}Qss$ and $\bar{Q}Qcc$, to obtain certain insights regarding the quark mass dependence of the static antiquark-antiquark interaction. We also discuss first steps regarding the static quark-antiquark case, i.e. $\bar{Q}Qll$, $\bar{Q}Qss$ and $\bar{Q}Qcc$.

$\bar{Q}Qqq$ systems as well as $Q\bar{Q}\bar{q}q$ systems have been studied also by other groups (cf. e.g. \cite{4, 5, 6, 7, 8, 9, 10, 11, 12}).

2. Creation operators and trial states
The $\bar{Q}Qqq$ and $\bar{Q}Q\bar{q}q$ potentials $V(r)$ are extracted from correlation functions

$$C(t) \equiv \langle \Omega | O^\dagger(t) O(0) | \Omega \rangle$$

according to

$$V(r) \text{ large } t \ \ V_{\text{eff}}(r, t) \ , \ \ V_{\text{eff}}(r, t) \equiv \frac{1}{a} \ln \left( \frac{C(t)}{C(t+a)} \right),$$

where $a$ is the lattice spacing and $O$ denote suitable creation operators, which are discussed in detail below. For an introduction to lattice hadron spectroscopy cf. e.g. \cite{13}.

2.1. Static-light mesons ("B and $\bar{B}$ mesons")
The starting point are static-light mesons, which either consist of a static quark $Q$ and an antiquark $\bar{q}$ or of a static antiquark $\bar{Q}$ and a quark $q$ with $q \in \{u,d,s,c\}$. These mesons can be labeled by parity $\mathcal{P} = \pm$, by the $z$-component of the light quark spin $j_z = \pm 1/2$ ($j = 1/2$, because we do not consider gluonic excitations) and in case of $q \in \{u,d\}$ by the $z$-component...
of isospin $I_z = \pm 1/2$ ($I = 1/2$). The lightest static-light meson has $\mathcal{P} = -$ and is commonly denoted by $S$, its heavier parity partner with $\mathcal{P} = +$ by $P_-$. The static-light meson $S$ is an approximation for $B/B^*, B_s/B_s^*$ and $B_c$ listed in [14].

We use static-light meson trial states

$$\mathcal{O}[\Omega] \equiv Q\Gamma q|\Omega\rangle$$

with $\Gamma \in \{\gamma_5, \gamma_0\gamma_5, \gamma_j, \gamma_0\gamma_j\}$ for the $S$ and $\Gamma \in \{1, \gamma_0, \gamma_j\gamma_5, \gamma_0\gamma_j\gamma_5\}$ for the $P_-$ meson. For a more detailed discussion of static-light mesons cf. [15, 16].

2.2. $B\bar{B}$ systems

We are interested in the potential of two static-light mesons, i.e. their energy as a function of their interactions involving the static quark spins, one should not couple static spins and spins of the quark. However, parity combined with charge conjugation, $\mathcal{P} \circ C$ is a symmetry and, therefore, a quantum number. When $q, \bar{q} \in \{u, d\}$, isospin $I \in \{0, 1\}$ and its $z$-component $I_z \in \{-1, 0, +1\}$ are also quantum numbers. In summary, there are up to five quantum numbers, which label $B\bar{B}$ states, $(I, I_z, |j_z|, \mathcal{P}, \mathcal{P}_z)$.

2.3. $BB$ systems (and $BB$ systems)

We use $BB$ trial states

$$\mathcal{O}[\Omega] \equiv (\mathcal{C}\Gamma)_{AB}\tilde{\Gamma}_{CD}\left(\hat{Q}_C^a(\vec{r}_1)\psi_A^{(f_1)a}(\vec{r}_1)\right)\left(\hat{Q}_D^b(\vec{r}_2)\psi_B^{(f_2)b}(\vec{r}_2)\right)|\Omega\rangle$$

with $\tilde{\Gamma} \in \{1, \gamma_0, \gamma_3\gamma_5, \gamma_1\gamma_2, \gamma_1\gamma_5, \gamma_2\gamma_5, \gamma_2\gamma_3, \gamma_1\gamma_3\}$ ($\mathcal{C} \equiv \gamma_0\gamma_5$ denotes the charge conjugation matrix). Arguments similar to those of the previous subsection lead to quantum numbers $(I, I_z, |j_z|, \mathcal{P}, \mathcal{P}_z)$. For a more detailed discussion cf. [1, 2].

3. Lattice setup

We use three ensembles of gauge link configurations generated by the European Twisted Mass Collaboration (ETMC) (cf. Table 1). For the $Q\bar{Q}qq$ potentials we use $N_f = 2$ ensembles with lattice spacing $a \approx 0.079$ fm for $q \in \{u, d\}$ and an even finer lattice spacing $a \approx 0.042$ fm for $q \in \{s, c\}$, because in the latter case the potentials are quite narrow. Existing $Q\bar{Q}qq$ results are
rather preliminary and have been obtained exclusively with \( q = c \) and the \( N_f = 2+1+1 \) ensemble with \( a \approx 0.086 \text{ fm} \). For details regarding these ETMC gauge link ensembles cf. \([17, 18, 19, 20, 21]\).

Correlation functions have been computed using around 100 gauge link configurations from each of the three ensembles. We have checked that these correlation functions transform appropriately with respect to the symmetry transformations (1) twisted mass time reversal, (2) twisted mass parity, (3) twisted mass \( \gamma_5 \)-hermiticity, (4) charge conjugation and (5) cubic rotations. In a second step we have averaged correlation functions related by those symmetries to reduce statistical errors.

### 4. Numerical results

#### 4.1. \( \bar{Q}Qqq \) potentials

In the following we focus on the attractive channels between ground state static-light mesons (\( S \) mesons). For \( q \in \{u, d\} \) there is a more attractive scalar isosinglet \( \langle qq = (ud - du)\rangle/\sqrt{2} \), \( \Gamma = \gamma_5 + \gamma_0 \gamma_5 \) corresponding to quantum numbers \((I, |j_z|, \mathcal{P}, \mathcal{P}_z) = (0, 0, -+, +)\) and a less attractive vector isotriplet \( \langle qq \in \{uu, (ud+du)/\sqrt{2}, dd\}\rangle, \Gamma = \gamma_j + \gamma_0 \gamma_j \) corresponding to quantum numbers \((I, |j_z|, \mathcal{P}, \mathcal{P}_z) = (1, \{0,1\}, -+, \pm)\).

For \( qq = ss \) there is only a single attractive channel, the equivalent of the vector isotriplet. To study also the scalar isosinglet with \( s \) quarks, we consider two quark flavors with the mass of the \( s \) quark, i.e. \( qq = (s_1s_2 - s_2s_1)/\sqrt{2} \). Similarly we consider \( qq = (c_1c_2 - c_2c_1)/\sqrt{2} \) to study a charm scalar isosinglet.

Proceeding as in \([3]\) we perform \( \chi^2 \) minimizing fits of

\[
V(r) = -\frac{\alpha}{r} \exp \left(-\left(\frac{r}{d}\right)^p\right)
\]

with respect to the parameters \( d \) (light isotriplet), \((d, \alpha) \) (\( q = s \) or \( q = c \)) or \((d, \alpha, p) \) (light isosinglet) to the lattice results for the \( \bar{Q}Qqq \) potentials. The resulting functions \( V(r) \) are shown in Figure 1.

To determine, whether the investigated mesons may form a bound state, i.e. a tetraquark, we insert the potentials shown in Figure 1 into Schrödinger’s equation with reduced mass \( \mu \equiv m(S)/2 \) and solve it numerically (cf. \([3]\) for details). While there is strong indication for a bound state in the light scalar isosinglet channel, there seems to be no binding for the light vector isotriplet, or when \( q = s \) or \( q = c \). To quantify these statements, we list in Table 2 the factor by which the reduced mass \( \mu \) has to be multiplied to obtain a bound state with confidence level \( 1 \sigma \) and \( 2 \sigma \), respectively (the factors \( \leq 1.0 \) in the light scalar isosinglet indicate binding). These results clearly show that meson-meson bound states are more likely to exist for \( B \) mesons than for \( B_s \) or \( B_c \) mesons. In other words it seems to be essential for a tetraquark to have both heavy quarks (leading a large reduced mass \( \mu \)) and light quarks (resulting in a deep and wide potential).

| Ensemble  | \( N_f \) | \( \beta \) | \( (L/a)^3 \times (T/a) \) | \( a\mu_1 \) | \( a\mu_2 \) | \( a\mu_3 \) | \( a \) | \( m_\pi \) |
|-----------|---------|---------|----------------|--------|--------|--------|--|--------|
| A40.24    | 2       | 3.90    | \( 24^3 \times 48 \) | 0.00400| -      | -      | 0.079 fm | 340 MeV |
| E17.32    | 2       | 4.35    | \( 32^3 \times 64 \) | 0.00175| -      | -      | 0.042 fm | 352 MeV |
| A40.24    | 2+1+1   | 1.90    | \( 24^3 \times 48 \) | 0.00400| 0.15   | 0.19   | 0.086 fm | 332 MeV |

**Table 1.** ETMC gauge link ensembles used in this work.
Figure 1. $\bar{Q}Qqq$ potentials (6) for $q = u/d$, $q = s$ and $q = c$ (error bands are not shown). (a) Scalar isosinglet. (b) Vector isotriplet.

| flavor          | light | strange | charm |
|-----------------|-------|---------|-------|
| confidence level for binding | $1\,\sigma$ | $2\,\sigma$ | $1\,\sigma$ | $2\,\sigma$ |
| scalar isosinglet | 0.8   | 1.0     | 1.9   | 2.2   | 3.1 | 3.2 |
| vector isotriplet | 1.9   | 2.1     | 2.5   | 2.7   | 3.4 | 3.5 |

Table 2. Factors, by which the reduced mass $\mu = m(S)/2$ in Schrödinger’s equation has to be multiplied to obtain a four-quark bound state with confidence level $1\,\sigma$ and $2\,\sigma$, respectively.

4.2. $\bar{Q}Q\bar{q}q$ potentials
At the moment there are only preliminary results for $\bar{Q}Q\bar{q}q$ potentials corresponding to isospin $I = 1$ and $q = c$, i.e. $\bar{q}q = (\bar{c}_1c_2 - \bar{c}_2c_1)/\sqrt{2}$. Interestingly we observed that all these potentials are attractive, while in the $\bar{Q}Qqq$ case only half of them are attractive and the other half is repulsive. This can be understood in a qualitative way by comparing the potential of $\bar{Q}Q$ and of $\bar{Q}Q$ generated by one-gluon exchange. For $\bar{Q}Q$ the Pauli principle applied to $qq$ implies either a symmetric (sextet) or an antisymmetric (triplet) color orientation of the static quarks corresponding to a repulsive or attractive interaction, respectively. For $\bar{Q}Q$ no such restriction is present, i.e. all channels contain contributions of the attractive color singlet, which dominates the repulsive color octet.

$I = 0$ requires the computation of an additional diagram and $u/d$ and $s$ quarks are more demanding with respect to HPC resources than $c$ quarks. We expect corresponding results to be available soon.

5. Conclusions
We have obtained insights regarding the quark mass dependence of $\bar{Q}Qqq$ potentials, which suggest that tetraquark states with two heavy $\bar{b}$ antiquarks seem to be more likely to exist, when there are also two light $u/d$ quarks involved but not $s$ or $c$ quarks.

Preliminary results for $\bar{Q}Q\bar{q}q$ potentials indicate that there are only attractive channels, which is in contrast to the $\bar{Q}Qqq$ case.
