COHOMOLOGY AND THE BOWDITCH BOUNDARY

JASON FOX MANNING AND OLIVER WANG

Abstract. We give a group cohomological description of the Čech cohomology of the Bowditch boundary of a relatively hyperbolic group pair, generalizing a result of Bestvina–Mess about hyperbolic groups. In case of a relatively hyperbolic Poincaré duality group pair, we show the Bowditch boundary is a homology manifold. For a three-dimensional Poincaré duality pair, we recover the theorem of Tshishiku–Walsh stating that the boundary is homeomorphic to a two-sphere.

1. Introduction

In Gromov’s influential essay on hyperbolic groups [Gro87], he introduced a compactification, now called the Gromov boundary and initiated a study of the dynamics of a hyperbolic group on its boundary. Later, Bowditch showed that boundaries of hyperbolic groups are completely characterized by this dynamical structure, which mirrors the dynamics of a convex cocompact Kleinian group [Bow98]. Bestvina and Mess in [BM91] showed that this boundary also contains algebraic information about the group, by showing, for any hyperbolic group $G$, any $k \geq 1$ and any commutative ring $A$, there is an isomorphism $H^k(G; AG) \cong \tilde{H}^{k-1}(\partial G; A)$ between the group cohomology of $G$ and the Čech cohomology of its boundary. (Throughout this paper Čech cohomology is reduced, and $A$ is some fixed commutative ring.) Note there is a natural map from $\partial G$ to the space of ends of a hyperbolic group, collapsing components of $\partial G$ to points, so this is consistent with the isomorphism $H^1(G; \mathbb{Z}G) \cong \tilde{H}^0(\text{Ends}(G); \mathbb{Z})$, as described, for example in [Geo08, Chapter 13].

Gromov also introduced the idea of a relatively hyperbolic group pair in [Gro87], which attracted little attention until the work of Farb in the mid-90s [Far98]. In Bowditch’s 1999 preprint, published as [Bow12], a boundary was described for such a pair. The dynamics of a relatively hyperbolic group pair acting on this boundary mirror the dynamics of a geometrically finite Kleinian group acting on its limit set. Yaman proved an analogue of Bowditch’s result about hyperbolic groups, that a group action on a metrizable compactum satisfying certain dynamical criteria must be relatively hyperbolic, and the compactum must be equivariantly homeomorphic to the Bowditch boundary [Yam04]. In this paper we show an analogue of Bestvina and Mess’s result in the relatively hyperbolic setting.

Theorem 1.1. If $(G, \mathcal{P})$ is relatively hyperbolic and type $F_\infty$, then for every $k$, there is an isomorphism of $AG$-modules

$$H^k(G, \mathcal{P}; AG) \cong \tilde{H}^{k-1}(\partial(G, \mathcal{P}); A).$$

We recall Bieri and Eckmann’s definition of relative group cohomology [BE78] in Section 2.4. A group is type $F$ (resp. type $F_\infty$) if it admits an Eilenberg-MacLane classifying space with finitely many cells (resp. finitely many cells in each dimension). A pair $(G, \mathcal{P})$ is type $F$ or $F_\infty$ if both $G$ and every $P \in \mathcal{P}$ are.

Theorem 1.1 implies that in some sense all the high-dimensional group cohomology of $G$ comes from its peripheral groups $\mathcal{P}$ (see Corollary 3.22).

1In that work a relatively hyperbolic pair is called a strongly relatively hyperbolic pair.
Theorem 1.1 was previously obtained by Kapovich in case $G$ is geometrically finite Kleinian and $\mathcal{P}$ is the collection of maximal parabolic subgroups, up to conjugacy in $G$ [Kap09]. In that case the Bowditch boundary $\partial(G, \mathcal{P})$ is equivariantly homeomorphic to the limit set $Λ(G)$.

**Question 1.2.** Do the isomorphisms (1) hold without the assumption that the pair is $F_\infty$?

Poincaré duality group pairs are of particular interest. In this context, we show the following analogue of [Bes96, Theorem 2.8].

**Theorem 1.3.** Suppose $(G, \mathcal{P})$ is relatively hyperbolic and type $F$. The following are equivalent:

1. $(G, \mathcal{P})$ is a PD($n$) pair.
2. $\partial(G, \mathcal{P})$ is a homology $(n-1)$–manifold and an integral Čech cohomology $(n-1)$–sphere.

In the particular case that $n = 3$, then we recover a result of Tshishiku and Walsh [TW17]. Namely, $(G, \mathcal{P})$ is a PD(3) pair if and only if $\partial(G, \mathcal{P})$ is homeomorphic to a 2–sphere (see Corollary 1.3).

1.1. **Outline.** In Section 2, we recall some basic facts about relative hyperbolicity and various cohomology theories which occur in the paper. Some of this is expanded on further in an appendix.

In Section 3, we construct, for an $F_\infty$ relatively hyperbolic group pair, a sequence of more and more highly connected metric spaces on which the pair acts in a cusp uniform manner. We show that the Bowditch boundary compactifies these spaces as kind of weak $Z$–set (see Corollary 3.17).

In any case, it has enough of the properties of a $Z$–set that we can establish Theorem 1.1, which we do in subsection 3.6.

In Section 4, we restrict attention to relatively hyperbolic PD($n$) pairs and adapt an argument of Bestvina from [Bes96] to show Theorem 1.3. The key idea here, also used in the final section, is that the cellular/simplicial chain complex of the cusped space we build is “regular”, in the sense that coboundaries with support near a point at infinity are coboundaries of cochains which are also supported near that point at infinity.

Finally in Section 5, we show (Theorem 5.1) that the topological dimension of the Bowditch boundary can be computed from relative group cohomology, at least with the hypothesis that $\text{cd}(G) < \text{cd}(G, \mathcal{P})$. We conjecture the hypothesis is not necessary (Conjecture 5.3).

1.2. **Acknowledgments.** The authors thank Ken Brown, Ross Geoghegan, Mike Mihalik, Alessandro Sisto and Jim West for useful conversations. This project was supported by the National Science Foundation, grant DMS-1462263, and by a grant from the Simons Foundation (524176, JFM).

2. **Preliminaries**

This section of background material can be skimmed on first reading and referred back to as necessary.

2.1. **Gromov hyperbolic spaces.** We refer to [BH99, III.H] for more detail about hyperbolic metric spaces. We review just enough to fix notation. Metrics will mostly be written $d(\cdot, \cdot)$, with the specific metric space evident from context. Sometimes the metric on a space $S$ will be written $d_S(\cdot, \cdot)$.

Let $\delta \geq 0$. A $\delta$–hyperbolic space is a geodesic metric space so that every geodesic triangle is $\delta$–thin, i.e. the canonical map to the comparison tripod has fibers of diameter at most $\delta$. The Gromov product $(x|y)_z = \frac{1}{2}(d(z, x) + d(z, y) - d(x, y))$ is the distance from the center of this tripod to the comparison point for $z$. In a $\delta$–hyperbolic space, $(x|y)_z$ is within $\delta$ of the distance between $z$ and any geodesic joining $x$ to $y$.

A geodesic space is Gromov hyperbolic if it is $\delta$–hyperbolic for some $\delta$. If $X$ is Gromov hyperbolic, and $z \in X$ a basepoint, we say that $\{x_i\}_{i \in \mathbb{N}}$ tends to infinity if $\lim_{i,j \to \infty} (x_i|x_j)_z = \infty$. The Gromov boundary $\partial X$ of $X$ is the set of equivalence classes of sequences which go to infinity, where
\{x_i\}_{i \in \mathbb{N}} \sim \{y_i\}_{i \in \mathbb{N}} \text{ if } \lim_{i,j \to \infty} (x_i, y_j)_z = \infty. \text{ Whether a sequence goes to infinity is independent of the basepoint } z.

The Gromov product extends to the boundary; if \( x \) and \( y \) are points in \( \partial X \),
\[
(x|y)_z = \sup_{i,j} \liminf_{i,j \to \infty} (x_i, y_j)_z
\]
where the supremum is taken over all \( \{x_i\}_{i \in \mathbb{N}} \) and \( \{y_i\}_{i \in \mathbb{N}} \) so that \( x = \{x_i\}_{i \in \mathbb{N}} \) and \( y = \{y_i\}_{i \in \mathbb{N}} \). Points inside \( X \) can be represented by constant sequences. Then a sequence \( \{x_i\}_{i \in \mathbb{N}} \) converges to \( y \in \partial X \) if
\[
\lim_{i \to \infty} (x_i|y)_z = \infty.
\]
This determines a topology on \( \overline{X} = X \cup \partial X \) which is independent of the choice of basepoint \( z \).

**Definition 2.2.** Suppose \( Y \) is any metric space, and \( D > 0 \), the **Rips complex on \( Y \) with parameter \( D \)** is the simplicial complex \( R_D(Y) \) whose vertex set is equal to \( Y \), so that distinct points \( \{x_0, \ldots, x_n\} \) span an \( n \)-simplex if \( \max\{d(x_i, x_j)\} \leq D \).

**Definition 2.2.** Suppose \( Y \) is any metric space, and \( Y_0 \subset Y \) is a locally finite \( C \)-dense subset. (Locally finite means every ball meets finitely many elements of \( Y_0 \); \( C \)-dense means that every point in \( Y \) is within \( C \) of some point of \( Y_0 \). To topologize \( R_D(Y_0) = R_D(Y_0) \cup \partial Y \), it suffices to describe a neighborhood basis for \( z \in \partial Y \). Fix a basepoint \( y_0 \in Y_0 \). For each \( n \geq 0 \), let \( V(z, n) \) be the subcomplex of \( R_D(Y_0) \) spanned by \( \{y \in Y_0 \mid (y|z)_{y_0} \geq n\} \) (using the Gromov product in \( Y \)). These sets give a basis of closed neighborhoods of \( z \).

We need the following refinement of [BH99 III.Γ.3.23].

**Lemma 2.3.** Let \( Y \) be a \( \delta \)-hyperbolic space, let \( Y_0 \subset Y \) be a \( C \)-dense subset, and let \( R = R_D(Y_0) \) where \( D \geq 4\delta + 6C \). Let \( L \subset R \) be any finite \( k \)-dimensional complex, and \( x_0 \) a vertex of \( L \). Then there is a contraction of \( L \) to \( x_0 \) in the subcomplex of \( R^{(k+1)} \) spanned by elements of \( Y_0 \) which lie within \( C + \delta \) of some \( Y \)-geodesic joining \( x_0 \) to some vertex of \( L \).

**Proof.** A close reading of the proof of [BH99 III.Γ.3.23] yields the statement, as we now explain.

Given a \( k \)-complex \( L \) in \( R \) and a vertex \( x_0 \) of \( L \), one homotopes the complex \( L \) closer and closer to \( x_0 \), beginning with cells adjacent to a vertex \( v \) which is farthest in \( Y \) from \( x_0 \). To accomplish this homotopy, one must find an element \( v_1 \in Y_0 \) which is within \( R \) of every vertex of \( L \) adjacent to \( v \), and so that \( d_Y(v_1, x_0) \) is smaller than \( d_Y(v, x_0) \) by a definite amount. Then for each \( k \)-simplex \( \sigma \) of \( L \) containing \( v \), there is a \((k + 1)\)-simplex containing \( \sigma \) and the vertex \( v_1 \), and we can homotope \( L \) across this \((k + 1)\)-simplex. Ultimately the complex \( L \) will be homotoped into a single simplex \( \sigma_0 \) of which \( x_0 \) is a vertex, and it then can be contracted easily in the \((k + 1)\)-skeleton of that simplex.

The vertex \( v_1 \) is found by the following procedure: Let \( \gamma_v \) be a \( Y \)-geodesic from \( x_0 \) to \( v \), let \( y_v \) be a point on \( \gamma_v \) at distance \( D/2 \) from \( v \), and let \( v_1 \) be any point in \( Y_0 \) within \( C \) of \( y_v \). (See [BH99 III.Γ.3.23] for the proof that this vertex satisfies the necessary adjacencies.)

If \( v_1 \) is not now in a \( D \)-ball about \( x_0 \) it will eventually be the farthest vertex again, and we obtain another vertex \( v_2 \), and so on. Given \( v \), let \( v_1, \ldots, v_n \) be the collection of vertices obtained in this way, and note that these are precisely the vertices \( v \) passes through on the way to the simplex \( \sigma_0 \).

We claim that every vertex \( v_i \) lies within \( C + \delta \) of \( \gamma_v \), and we prove this by induction on \( i \). The vertex \( v_1 \) lies within \( C \) of \( \gamma_v \), so we can get started. Suppose that \( v_i \) lies within \( C + \delta \) of \( \gamma_v \), and let \( \gamma_i \) be the geodesic from \( v_i \) to \( x_0 \) we use to choose \( v_{i+1} \), and let \( y_i \) be the point on \( \gamma_i \) at distance \( D/2 \) from \( v_i \). See Figure 1. Note that \( v_i \) is at most distance \( C + \delta \) from some point \( z_i \in \gamma_i \), by induction, and that \( d(v_i, y_i) = D/2 > C + \delta \). By the thinness of the triangle with vertices \( x_0, v_i, z_i \), we have that \( y_i \) is at most \( \delta \) from \( \gamma_v \). Thus \( v_{i+1} \) is distance at most \( C + \delta \) from \( \gamma_v \).

With this lemma, we prove the following statement.
Proposition 2.4. Suppose $Y$ is $\delta$-hyperbolic. Let $Y_0 \subseteq Y$ be a $C$-dense locally finite subset. Let $R$ be as in Definition 2.3 and let $\bar{R} = R \cup \partial Y$. Then, for every $z \in \partial Y$ and every neighborhood $U \subseteq \bar{R}$ of $z$, there is a neighborhood $V \subseteq U$ of $z$ such that, for all $i$, every map $S^i \to V \setminus \partial Y$ is nullhomotopic in $U \setminus \partial Y$.

Proof. The proof of this proposition is essentially contained in the proof of [BM91] Theorem 1.2. There, the authors treat the case that $Y$ is a graph.

Let $z \in \partial Y$ and $U \subseteq \bar{R}$ be a neighborhood of $z$. Fix a point $y_0 \in Y$. There is a constant $c > 0$ such that $U$ contains the closure of the subcomplex of $R$ spanned by the vertices $v$ which satisfy $(v|z)_{y_0} \geq c$. Let $V$ be the closure of the subcomplex spanned by the vertices $v$ such that $(v|z)_{y_0} \geq 2c + C + 4\delta$. Let $f : S^i \to V \setminus \partial Y$ be a map. We may assume that the image of $f$ is contained in a finite subcomplex of $R$. Suppose $v_1$ and $v_2$ are vertices of this subcomplex. By Lemma 2.3, it suffices to show that, if $v$ is a vertex with $d(v, v_1) + d(v, v_2) \leq d(v_1, v_2) + 2(C + \delta)$ then $v \in U$. Let $v$ be such a vertex. We have $(v_1|v_2)_{y_0} \geq \min\{(v_1|z)_{y_0}, (v_2|z)_{y_0}\} - \delta \geq 2c + C + 3\delta$. Our assumption on $v$ gives $(v_1|v)_{y_0} + (v_2|v)_{y_0} \geq (v_1|v_2)_{y_0} + d(v, y_0) - C - \delta \geq 2c + 2\delta$. We may assume (possibly switching $v_1$ and $v_2$) that $(v_1|v)_{y_0} \geq c + \delta$. Then $(v|z)_{y_0} \geq \min\{(v_1|z)_{y_0}, (v_1|v)_{y_0}\} \geq c$ as desired. \hfill $\Box$

2.2. Cusped spaces, relative hyperbolicity, and the Bowditch boundary.

2.2.1. The combinatorial cusped space. Let $\Gamma$ be a graph.

Definition 2.5. The combinatorial horball based on $\Gamma$ is the graph with vertex set $\mathbb{Z}_{\geq 0} \times v(\Gamma)$ and the following edges:

1. A vertical edge between $(n, v)$ and $(n + 1, v)$
2. A horizontal edge between $(n, v)$ and $(n, w)$ whenever $d_{\Gamma}(v, w) \leq 2^n$

The combinatorial horball is denoted $CH(\Gamma)$ and is endowed with a metric giving all edges length 1. Define the depth of a vertex $(n, v)$ to be $n$ and extend this linearly over the edges.

Definition 2.6. In this paper, a group pair $(G, \mathcal{P})$ is a finitely generated group $G$ together with a finite collection $\mathcal{P}$ of finitely generated proper subgroups of $G$.

Definition 2.7. Let $(G, \mathcal{P})$ be a group pair. Suppose $S$ is a finite generating set for $G$ which contains finite generating sets for each $P \in \mathcal{P}$. (Such a generating set is called a compatible generating set.) For each left coset $gP$ of some $P \in \mathcal{P}$ there is a copy $\Gamma_{gP}$ of the Cayley graph $\Gamma(P, P \cap S)$ contained in the Cayley graph $\Gamma(G, S)$. The combinatorial cusped space $XC_{CH}(G, \mathcal{P}, S)$ is obtained from $\Gamma(G, S)$ by gluing, to each such coset, a copy of the combinatorial horball based on $\Gamma(P, P \cap S)$.

There are many equivalent definitions of relative hyperbolicity (see [Hru10]). The following definition is from [GM08].

Definition 2.8. The pair $(G, \mathcal{P})$ is relatively hyperbolic if some (equivalently any) combinatorial cusped space $XC_{CH}(G, \mathcal{P}, S)$ is Gromov hyperbolic.

Remark. The combinatorial cusped space defined in [GM08] also has 2-cells which make it simply connected. We will only use the 1-skeleton in this paper, preferring a different method for obtaining a cusped space with higher connectedness properties (Section 3).
2.2.2. Bowditch boundary.

**Definition 2.9.** Let \((G, \mathcal{P})\) be a relatively hyperbolic pair. The Gromov boundary of the combinatorial cusped space is denoted \(\partial(G, \mathcal{P})\), and called the Bowditch boundary of \((G, \mathcal{P})\).

The pair \((G, \mathcal{P})\) acts on \(\partial(G, \mathcal{P})\) as a geometrically finite convergence group. This means the following:

1. \(G \acts \partial(G, \mathcal{P})\) is convergence, meaning \(G\) acts properly discontinuously on the set of distinct triples of points in \(\partial(G, \mathcal{P})\).
2. Every \(z \in \partial(G, \mathcal{P})\) is either
   a) a conical limit point, meaning there is a sequence \(\{g_i\}_{i\in\mathbb{N}}\) and a pair of distinct points \(a, b \in \partial(G, \mathcal{P})\) so that \(\lim_{i\to\infty} g_i(z) = b\) and \(\lim_{i\to\infty} g_i(x) = a\) uniformly for all \(x \neq z\), or
   b) a bounded parabolic point, meaning that the stabilizer of \(z\) acts properly cocompactly on \(\partial(G, \mathcal{P}) \setminus \{z\}\).
3. Each \(P \in \mathcal{P}\) is the stabilizer of some bounded parabolic point, and every bounded parabolic point has stabilizer conjugate to exactly one \(P \in \mathcal{P}\).

The following theorem of Yaman shows the Bowditch boundary is well-defined.

**Theorem 2.10.** \([Yam04]\) Let \(M\) be a nonempty perfect metrizable compactum with a \(G\)-action. The following are equivalent:

1. \((G, \mathcal{P})\) acts as a geometrically finite convergence group on \(M\).
2. \((G, \mathcal{P})\) is relatively hyperbolic and \(M\) is equivariantly homeomorphic to \(\partial(G, \mathcal{P})\).

Note that \(\partial(G, \mathcal{P})\) is perfect so long as \(\mathcal{P}\) contains no finite group.

2.2.3. Finite index subgroups.

**Definition 2.11.** Let \((G, \mathcal{P})\) be a group pair. Suppose that \(H < G\) is finite index. We define an induced peripheral structure \(\mathcal{P}_H\) on \(H\). For each \(i\), let \(D_i\) be a collection of representatives of double coset space \(H\backslash G/P_i\), and define

\[
P_H = \{H \cap dP_i d^{-1} \mid d \in D_i, P_i \in \mathcal{P}\}.
\]

**Lemma 2.12.** If \((G, \mathcal{P})\) is relatively hyperbolic, and \(H < G\) is finite index, then \((H, \mathcal{P}_H)\) is relatively hyperbolic, and \(\partial(H, \mathcal{P}_H) \cong \partial(G, \mathcal{P})\).

**Proof.** The subgroup \(H\) acts as a geometrically finite convergence group on \(\partial(G, \mathcal{P})\), and every parabolic fixed point has stabilizer conjugate in \(H\) to exactly one \(P \in \mathcal{P}_H\). Yaman’s theorem \([2.10]\) implies that \((H, \mathcal{P}_H)\) is relatively hyperbolic with Bowditch boundary homeomorphic to \(\partial(G, \mathcal{P})\). □

2.3. Čech Cohomology and Singular Cohomology.

**Definition 2.13.** A space \(X\) is homologically locally connected in dimension \(n\) (or \(HLC^n\)) if, for each \(x \in X\) and neighborhood \(U\) of \(x\), there is a neighborhood \(V \subseteq U\) of \(x\) such that the induced map \(H_i(V; \mathbb{Z}) \to H_i(U; \mathbb{Z})\) on reduced homology is trivial for \(i \leq n\).

The following proposition is in Spanier \([Spa89\] Corollaries 6.8.8 and 6.9.5].

**Proposition 2.14.** Suppose \(X\) is \(HLC^n\), Hausdorff, and paracompact. Let \(A\) be an abelian group. Then, \(H^i(X; A) \cong H^i(X; A)\) for \(i = 0, \ldots, n\).

2.4. Cohomology of Group Pairs.

**Notation 2.15.** When we write \(\text{Hom}_G, \text{Ext}_G\) and \(\text{Tor}^G\), we take this to mean the \(\text{Hom}_{\mathbb{Z}G}, \text{Ext}_{\mathbb{Z}G}\) and \(\text{Tor}^{\mathbb{Z}G}\), respectively. We let \(A\) denote a (discrete) ring. The cohomology of a group with coefficients in \(M\), \(H^i(G; M)\), is \(\text{Ext}_G^i(\mathbb{Z}; M)\) and the homology, \(H_k(G; M)\), is \(\text{Tor}_k^G(\mathbb{Z}; M)\) where \(\mathbb{Z}\) has a trivial \(G\)-action.
The cohomology of a group pair will be defined following [BE78]. Let \( G \) be a group and let \( \mathcal{P} \) be a family of subgroups. Define the \( G \)-module \( ZG/\mathcal{P} := \bigoplus_{\mathcal{P} \in \mathcal{P}} Z[G/\mathcal{P}] \) and let \( \Delta_{G/\mathcal{P}} \) be the kernel of the augmentation \( ZG/\mathcal{P} \to \mathbb{Z} \). Then, for a \( G \)-module \( M \), the relative cohomology groups \( H^k(G, \mathcal{P}; M) \) are defined to be \( \text{Ext}^k(\Delta_{G/\mathcal{P}}, M) \). Similarly, the relative homology groups \( H_k(G, \mathcal{P}; M) \) are defined to be \( \text{Tor}^k_{G}(\Delta_{G/\mathcal{P}}, M) \).

Remark. We recall what this means: Let \( \mathcal{F} \) be a free resolution of the \( \mathcal{P} \)-module \( \Delta \mathcal{P} \). Define the \( G \)-module \( ZG/\mathcal{P} := \bigoplus_{\mathcal{P} \in \mathcal{P}} Z[G/\mathcal{P}] \) and let \( \Delta_{G/\mathcal{P}} \) be the kernel of the augmentation \( ZG/\mathcal{P} \to \mathbb{Z} \). Then, for a \( G \)-module \( M \), the relative cohomology groups \( H^k(G, \mathcal{P}; M) \) are defined to be \( \text{Ext}^k(\Delta_{G/\mathcal{P}}, M) \). Similarly, the relative homology groups \( H_k(G, \mathcal{P}; M) \) are defined to be \( \text{Tor}^k_{G}(\Delta_{G/\mathcal{P}}, M) \).

The dimension shift is clarified if one imagines the resolution coming from a contractible simplicial complex \( K \) with \( G \)-action chosen so that the stabilizers of vertices are the conjugates of elements of \( \mathcal{P} \), but that all other cell stabilizers are trivial. We can then identify \( \mathcal{P} \)-module, then there are the following diagrams of long exact sequences of pairs.

 Crucially, there are long exact sequences of pairs.

**Proposition 2.16.** [BE78 Prop 1.1] For any group pair \((G, \mathcal{P})\) and any \( G \)-module \( M \), there are long exact sequences in cohomology and homology:

\[
\ldots \to H^k(G; M) \to H^k(\mathcal{P}; M) \to H^{k+1}(G, \mathcal{P}; M) \to H^{k+1}(G; M) \to \ldots
\]

\[
\ldots \to H_{k+1}(G; M) \to H_{k+1}(G, \mathcal{P}; M) \to H_k(\mathcal{P}; M) \to H_k(G; M) \to \ldots
\]

where \( H^k(\mathcal{P}; M) := \bigoplus_{\mathcal{P} \in \mathcal{P}} H^k(\mathcal{P}; M) \) and \( H_k(\mathcal{P}; M) := \bigoplus_{\mathcal{P} \in \mathcal{P}} H_k(\mathcal{P}; M) \).

Let \( K \) be a \( K(G, 1) \) cell complex and let \( \{L_P\}_{P \in \mathcal{P}} \) be disjoint \( K(P, 1) \) subcomplexes such that each inclusion induces the inclusion \( P \to G \) on \( \pi_1 \) (after a choice of path connecting the base points). Let \( L := \bigcup_{P \in \mathcal{P}} L_P \). Then \((K, L)\) is called an Eilenberg-MacLane pair for \((G, \mathcal{P})\). Bieri and Eckmann provide a topological interpretation of the relative cohomology groups.

**Theorem 2.17.** [BE78 Thm 1.3] If \((K, L)\) is an Eilenberg-MacLane pair for \((G, \mathcal{P})\) and \( M \) is a \( G \)-module, then there are the following diagrams of long exact sequences:

\[
\begin{array}{ccccccc}
\ldots & \to & H^k(G; \mathcal{P}; M) & \to & H^k(G; M) & \to & H^k(\mathcal{P}; M) & \to & H^{k+1}(G, \mathcal{P}; M) & \to & \ldots \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
\ldots & \to & H^k(K, L; M) & \to & H^k(K; M) & \to & H^k(L; M) & \to & H^{k+1}(K, L; M) & \to & \ldots \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
\ldots & \to & H_k(L; M) & \to & H_k(K; M) & \to & H_k(K, L; M) & \to & H_{k-1}(L; M) & \to & \ldots \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
\ldots & \to & H_k(\mathcal{P}; M) & \to & H_k(G; \mathcal{P}; M) & \to & H_k(G, \mathcal{P}; M) & \to & H_{k-1}(\mathcal{P}; M) & \to & \ldots
\end{array}
\]

which are commutative up to sign and where the vertical arrows are isomorphisms.

In proving Theorem 2.17, Bieri and Eckmann prove the following statement.

**Proposition 2.18.** Let \((K, L)\), \((G, \mathcal{P})\) and \( M \) be as in 2.17. Let \( \tilde{K} \) be the universal cover of \( K \) and let \( \tilde{L} \) be the preimage of \( L \) under \( \tilde{K} \to K \). If \( C_*(\tilde{K}, \tilde{L}) \) is the relative chain complex (this can be singular, cellular or simplicial), then the homology of \( C_*(\tilde{K}, \tilde{L}) \otimes_G M \) is \( H_*(G, \mathcal{P}; M) \) and the cohomology of \( \text{Hom}_G(C_*(\tilde{K}, \tilde{L}); M) \) is \( H^*(G, \mathcal{P}; M) \).
Following [Kap09], we make the following definitions

**Definition 2.19.** Suppose \((G, \mathcal{P})\) satisfies the following

i) \(G\) and each \(P \in \mathcal{P}\) is type FP

ii) \(\mathcal{P}\) is a finite collection of subgroups

Then the pair \((G, \mathcal{P})\) is type FP.

**Remark.** In the case that \((G, \mathcal{P})\) is torsion-free relatively hyperbolic and \(\mathcal{P}\) consists of type \(F\) subgroups, Dahmani shows that \((G, \mathcal{P})\) is type FP [Dah03].

**Definition 2.20.** The **cohomological dimension** of \((G, \mathcal{P})\) is

\[ \text{cd}(G, \mathcal{P}) := \max\{n \in \mathbb{N} \mid H^n(G, \mathcal{P}; M) \neq 0 \text{ for some } \mathbb{Z}G\text{-module } M \} \]

Kapovich observes that the following statement can be proved in the same way as the corresponding absolute statement.

**Proposition 2.21.** [Kap09] Lemma 2.9] If \((G, \mathcal{P})\) is type FP, then

\[ \text{cd}(G, \mathcal{P}) = \sup\{n \in \mathbb{N} \mid H^n(G, \mathcal{P}; \mathbb{Z}) \neq 0 \} \]

3. An \(N\)-connected cusped space for \((G, \mathcal{P})\).

The combinatorial cusped space described in [GM08] and the relative Cayley complex described in [Osi06] are well-suited for arguments involving 2-dimensional filling problems, but are not so useful for higher-dimensional homotopy theoretic arguments. Dahmani shows in [Dah03] that if the peripheral subgroups of a pair \((G, \mathcal{P})\) have finite classifying spaces, then these can be extended to give a finite-dimensional classifying space for \(G\) provided that \(G\) is torsion free. Moreover he is able to build a \(\mathbb{Z}\)-set compactification of \(G\), given such compactifications for the peripherals. In the present work, we do not want to assume type \(F\), but only type \(F_\infty\), and moreover we do not want to assume that the peripherals have nice compactifications, so we take different approach. We build, for each \(N\), an \(N\)-connected finite dimensional version of the cusped space, for which the Bowditch boundary will form a kind of “weak \(Z\)-set compactification”.

Accordingly, we fix \((G, \mathcal{P})\) an \(F_\infty\) group pair with \(\mathcal{P}\) a finite family of subgroups, and an integer \(N\). We will build a locally compact \(N\)-connected metric simplicial complex \(X(G, \mathcal{P}, N)\) quasi-isometric to the cusped space for \(N \geq 0\). Since the group pair will be fixed, we will write \(X(N)\). The main tool for constructing this space is the warped product, which was first extended to the metric geometry setting by Chen [Che99].

**Definition 3.1.** Let \(X\) and \(Y\) be two length spaces and let \(f : X \to [0, \infty)\) be a continuous function. Let \(\gamma : [0, 1] \to X \times Y\) be a path where \(\gamma(t) = (\alpha(t), \beta(t))\). Suppose \(\tau = \{0 = t_0 < \ldots < t_n = 1\}\) is a partition of the interval and define

\[ \ell_\tau(\gamma) = \sum_{i=1}^{n} \left( d_X(\alpha(t_i), \alpha(t_{i-1}))^2 + f(\alpha(t_i))^2 d_Y(\beta(t_i), \beta(t_{i-1}))^2 \right)^{\frac{1}{2}} \]

The length of \(\gamma\) is defined to be the supremum of \(\ell_\tau(\gamma)\) over all partitions \(\tau\). This gives a pseudometric on \(X \times Y\) and, if \(f\) has no zeros, a metric. The resulting space with this pseudometric is the **warped product of \(X\) and \(Y\) with respect to \(f\)** and is denoted as \(X \times_f Y\).

**Definition 3.2** (The \(N\)-Connected Cusped Space). By assumption both \(G\) and the members of \(\mathcal{P}\) have classifying spaces with finitely many cells in each dimension. Let \(B_G\) and \(B_P\) for \(P \in \mathcal{P}\) be (pointed) \((N + 1)\)-skeleta of such classifying spaces, chosen to have the following extra properties:

1. The universal covers \(E_G \to B_G\) and \(E_P \to B_P\) for \(P \in \mathcal{P}\) are simplicial complexes.

2. For each \(P \in \mathcal{P}\), an inclusion \(i_P : B_P \to B_G\) induces the inclusion of \(P\) into \(G\).

**Remark.** The notation \(B_G\) and \(E_G\) is meant to emphasize that the spaces involved in this construction come from classifying spaces and their universal covers but that \(B_G \nRightarrow BG\) and \(E_G \nRightarrow EG\) in general.
Now let $\text{Cyl}$ be the open mapping cylinder of $\iota_P \sqcup \bigcup_P B_P \to B_G$, i.e.

$$\text{Cyl} = B_G \sqcup \left([0, \infty) \times \bigcup_P B_P\right) \bigg/ \operatorname{t}_P(x) \sim (0, x).$$

See Figure 2. As a topological space, $\mathcal{X}(N)$ is the universal cover of $\text{Cyl}$. There is a $G$–equivariant simplicial structure whose $0$–simplices are the $0$–simplices of the universal cover $E_G$ of $B_G$ together with all the points in the preimage of $(v, n)$ where $v$ is a vertex of some $B_P$ and $n \in \mathbb{Z}_{\geq 0}$. We also assume that the cell structure on each $[0, \infty) \times B_P$ is chosen in some standard way, so that the shift $(t, k) \mapsto (t + 1, k)$ gives a simplicial embedding of $[0, \infty) \times B_P$ into itself.

We next describe a path metric on $\mathcal{X}(N)$ by putting path metrics on various subsets. Simplices in the universal cover $E_G$ of $B_G$ are metrized as regular euclidean simplices with unit edge lengths. Let $H$ be a component of the preimage of some $[0, \infty) \times B_P$ (henceforth called a horoball). For each $P$, the universal cover $E_P$ of $B_P$ inherits a path metric from $E_G$, and we use this path metric to metrize $H$ as a warped product

$$H = [0, \infty) \times_{2^{-t}} E_P.$$

Equipped with this metric and simplicial structure, $\mathcal{X}(N)$ will be called the $N$–connected cusped space.

Remark. The proper space studied by Bowditch in [Bow12] can be recovered as a special case when the complexes $B_G$ and $B_P$ each have a single 0-cell, if we take $N = 0$ and replace the warping function $2^{-t}$ with $e^{-t}$. In fact the exact exponential warping function is not important to the quasi-isometry type, and by [GMS16, Prop 2.22] this space is always equivariantly quasi-isometric to the combinatorial cusped space from Definition 2.7.

Definition 3.3. Let $x \in \text{Cyl}$. If $x$ can be identified with a point $(t, y) \in [0, \infty) \times B_P$ then we define the depth of $x$ (denoted $\text{Depth}(x)$) to be $t$. Otherwise, $\text{Depth}(x) = 0$.

If $\hat{x} \in \mathcal{X}(N)$, then $\text{Depth}(\hat{x}) := \text{Depth}(x)$ where $x$ is the image of $\hat{x}$ under $\mathcal{X}(N) \to \text{Cyl}$.

The following is immediate from the construction.

Lemma 3.4. Each simplex of $\mathcal{X}(N)$ has bounded diameter, and there is a $C > 0$ so that the 0–skeleton is $C$–dense. In particular nearest-point projection to the 0–skeleton is a quasi-isometry.

3.1. Hyperbolicity of the $N$–connected cusped space. In this subsection we prove:

Proposition 3.5. $\mathcal{X}(N)$ is quasi-isometric to $X_{CH}$. In particular, $\mathcal{X}(N)$ is Gromov hyperbolic if and only if $(G, \mathcal{P})$ is relatively hyperbolic.
Proof. By Lemma 3.4, it suffices to show that there is a quasi-isometry between \( \mathcal{X}(N)^{(0)} \) and \( X_{CH}^{(0)} \). We show there are coarsely Lipschitz quasi-inverse maps between \( \mathcal{X}(N)^{(0)} \) and the 0–skeleton
\[
X_{CH}^{(0)} = G \sqcup \bigsqcup_{gP \in G/P} \bigcup_{P} \bigsqcup_{Z > 0} \times gP
\]
of the combinatorial cusped space. It follows easily that these maps are quasi-isometries. We then conclude using the quasi-isometric invariance of Gromov hyperbolicity.

We first define \( \iota: X_{CH}^{(0)} \rightarrow \mathcal{X}(N)^{(0)} \). Using the notation in Definition 3.2, let \( W \subset \text{Cyl} \) be a wedge of rays centered at the basepoint \( b_G \) of \( B_G \), so each ray is equal to the ray \([0, \infty) \times b_P \) inside \( \text{Cyl} \). Let \( \tilde{W} \) be a lift to the universal cover \( \mathcal{X}(N) \), and let \( \tilde{b}_G \) and \( (n, b_P) \) be the corresponding vertices of this lift. Define \( \iota(g) = g\tilde{b}_G \). For \( gp \in gP \) and \( n > 0 \) define \( \iota((n, gp)) = gp((n, b_P)) \).

The map \( \iota \) is injective with image in \( \mathcal{X}(N)^{(0)} \). Define \( \pi: \mathcal{X}(N)^{(0)} \rightarrow X_{CH}^{(0)} \) by \( \pi(x) = \iota^{-1}(\tilde{x}) \), where \( \tilde{x} \) is some closest point to \( x \) in the image of \( \iota \). Obviously \( \pi \circ \iota \) is the identity. Moreover, the image of \( \iota \) is \( K \)–dense for some \( K \), so \( \iota \circ \pi \) is within \( K \) of the identity. It is also easy to see that \( \iota \) is \( K \)–Lipschitz for some \( K \).

We now show that \( \pi \) is coarsely Lipschitz. Since the image of \( \iota \) is \( K \)–dense, a standard argument shows that, if we can find a bound on the diameter of \( \iota^{-1}(B_{3K}(p)) \) independent of \( p \in \mathcal{X}(N) \), then \( \pi \) is coarsely Lipschitz.

(Here is the standard argument: Given \( p, q \in \mathcal{X}(N) \), choose points \( p_0, \ldots, p_n \) on a geodesic from \( p \) to \( q \) so that \( p_0 = p_i, p_n = q \), and \( d(p_i, p_{i+1}) = K \), except that \( d(p_{n-1}, p_n) \leq K \). Then we have \( d(p, q) \geq (n-1)K \). Now choose points \( b_i = \iota(a_i) \) so that \( d(b_i, p_i) \leq K \), and \( a_0 = \pi(p), a_n = \pi(q) \). Now we estimate
\[
d(\pi(p), \pi(q)) \leq \sum_{i=1}^{n} d(a_{i-1}, a_i) \leq nR \leq \frac{R}{K}d(p, q) + R,
\]
where \( R \) is the bound on the diameter of \( \iota^{-1}(B_{3K}(p)) \).

Let \( E_G \subset \mathcal{X}(N) \) be the universal cover of the \((N+1)\)–skeleton of the classifying space \( B_G \). The \( G \)–action is cocompact in any closed equivariant neighborhood of \( E_G \), so there is some constant \( B_1 \) bounding the diameter of \( \iota^{-1}(B_{3K}(p)) \) for any \( p \) in the \( 12K \)–neighborhood of \( E_G \).

Let \( B \) be a \( 3K \)–ball in \( \mathcal{X}(N) \) whose center is in a horoball \( H \), at depth at least \( 12K \). Suppose \( H \) is stabilized by \( P^0 \), where \( P \subset P \). Then \( H \) is isometric to \([0, \infty) \times \pi \), \( \pi \) is the universal cover of \((N+1)\)–skeleton of \( B_P \) inside \( \text{Cyl} \), a classifying space for \( P \).

Let \( (n, x) \) and \( (m, y) \) be points of \( B \) in the image of \( \iota \), and let \( \gamma \) be a geodesic joining them. We may suppose \( n \leq m \), and that \( m - n \leq 6K \). By our assumptions, the geodesic \( \gamma \) lies entirely in \( H \), and can be written in terms of the product structure as \((\gamma_1, \gamma_2)\), where \( \gamma_2 \) is a geodesic in \( \pi \). Because of the warping of the metric, we have
\[
2^n l(\gamma_1) \geq l(\gamma_2).
\]
Since \( \gamma_2 \) has length at most \( 6K \), we get (writing \( d_{E_P} \) for the path metric on \( E_P \))
\[
d_{E_P}((0, x), (0, y)) \leq 6K 2^m.
\]
Note that \((0, x)\) and \((0, y)\) are in the image of \( \iota(gP) \). Let \( \Gamma_{gP} \) be the copy of the Cayley graph of \( P \) spanned by the vertices \( gP \) in \( X_{CH} \). Then \( \pi|_{E_P} : E_P \rightarrow \Gamma_{gP} \) is a \((\lambda, \epsilon)\)–quasi-isometry for some \( \lambda \geq 1 \) and \( \epsilon > 0 \) depending only on \( P \in \mathcal{P} \). We thus have
\[
d_{\Gamma_{gP}}(\pi((0, x)), \pi((0, y))) \leq 6K \lambda 2^m + \epsilon.
\]
It follows that
\[
d_{X_{CH}}(\pi((n, x)), \pi((n, y))) \leq 2^{m-n}(6K \lambda + 2^{-n} \epsilon + 1) \leq 2^{6K}(6K \lambda) + \epsilon + 1,
\]
and finally that
\[
d_{X_{CH}}(\pi((n, x)), \pi((m, y))) \leq 2^{6K}(6K \lambda) + \epsilon + 1 + 6K.
\]
The constants $\lambda$ and $\epsilon$ depended on $P$, but there are only finitely many possibilities, so taking the maximum gives us a universal bound $B_2$ on the diameter of $\iota^{-1}(B)$ where $B$ is a $3K$–ball whose center is at depth at least $12K$. Taking $\max\{B_1, B_2\}$ gives the desired universal bound for all $3K$–balls.

**Definition 3.6.** The quasi-isometry from Proposition 3.5 gives an identification of $\partial X_{CH}$ with $\partial(G, P)$. We use this identification and write $X(N) = X(N) \cup \partial(G, P)$.

### 3.2. Collapsing spheres near infinity.

The space $X(N)$ is Gromov hyperbolic (Proposition 3.5) and the 0–skeleton is $C$–dense (Lemma 3.4). We can therefore fix some $D \geq 1$ so that the conclusion of Lemma 2.3 holds, which means roughly that subcomplexes of the Rips complex $R = R_D(X(N)\langle 0 \rangle)$ can be contracted in their “convex hulls”.

**Definition 3.7.** A continuous map $r : R_D^{(N+1)} \to X(N)$ is depth preserving if, for each $a$ a simplex of $R_D$ and $I \subset [0, \infty)$ the smallest interval containing $\text{Depth}(\sigma^0)$,

$$\text{Depth}(r(\sigma)) \subset \begin{cases} [0, \sup I] & \text{inf } I \leq D \\ I & \text{inf } I > D \end{cases}$$

**Lemma 3.8.** There are equivariant proper maps $r : R_D^{(N+1)} \to X(N)$ and $t_k : X(N)^{(k)} \to R^{(k)}$ for each $k = 0, \ldots, N + 2$ satisfying the following:

1. $r$ is depth preserving.
2. If $k \leq N + 1$, then $r \circ t_k$ is the inclusion $X(N)^{(k)} \subseteq X(N)$.

**Proof.** The vertices of $R_D$ can be identified with the vertices of $X(N)$. In particular, since $D \geq 1$, any simplex of $X(N)$ corresponds to a simplex of $R_D^{(N+2)}$ with the same vertices. This correspondence gives us the inclusion $t_k : X(N)^{(k)} \to R^{(k)}$.

We will construct $r$ inductively. We use the identification already mentioned to define $r$ on $R^{(0)}$. Suppose $r$ has been extended to the a depth preserving map on the $j$–skeleton. Then, let $\sigma \subseteq R$ be an orbit representative $(j + 1)$-simplex. If $\sigma$ is present in $X(N)$, we define $r$ to be the inverse of $\iota$ on $\sigma$.

Otherwise, let $I = [a, b]$ be as in the definition above. Suppose first that $b > D$. Then, all of the vertices must be in the same horoball and $\text{Depth}(r(\sigma)) \subseteq [a, b]$. So $r(\sigma)$ is a horoball. In particular, $r(\sigma)$ is in the product of an $N$–connected space with $[a, b]$. Since $j \leq N$, we can extend this map to $\sigma$. Suppose that $b \leq D$. Then, $\text{Depth}(r(\sigma)) \leq D$. But the points of depth at most $D$ is an $N$–connected space. This allows us to extend $r$ to $\sigma$ as desired. We extend equivariantly to the simplices in the orbit of $\sigma$.

The map $r$ from Lemma 3.8 will not be a quasi-isometry in general, but the fact that it is depth preserving will allow us to extend it continuously to the boundary.

**Lemma 3.9.** Let $\{x_j\}_{j \in \mathbb{N}}$ and $\{y_j\}_{j \in \mathbb{N}}$ be sequences tending to infinity in $X(N)$ such that

1. $\lim_{j \to \infty} \min\{\text{Depth}(x_j), \text{Depth}(y_j)\} = \infty$;
2. for each $j$, $x_j$ and $y_j$ lie in the same horoball; and

Then $\{x_j\}_{j \in \mathbb{N}}$ and $\{y_j\}_{j \in \mathbb{N}}$ have the same limit point in $\partial(G, P)$.

**Proof.** Fix a basepoint $e \in X(N)$ at depth 0. For $j \in \mathbb{N}$, let $H_j$ be the horoball containing $x_j$ and $y_j$. If a horoball $H$ occurs infinitely often, then the common limit of the two sequences must be the horoball center.

Otherwise, we can pass to subsequences so that $d(e, H_j)$ is strictly increasing with $j$. The uniform quasi-convexity of horoballs implies that, for large $j$, any geodesic joining $x_j$ to $y_j$ is contained in $H_j$.

Suppose for a contradiction that the two sequences do not converge to the same point at infinity. Then there are indices $i_k, j_k \to \infty$ so that the Gromov products $(x_{i_k} | y_{j_k})_e$ are bounded. If $\gamma_k$ is a
geodesic joining \( x_{i_k} \) to \( y_{j_k} \), then \( d(e, \gamma_k) \) is likewise bounded. Using thin triangles, it follows that if \( \sigma_k \) is a geodesic joining \( x_{i_k} \) to \( x_{j_k} \), then \( d(e, \sigma_k) \) is bounded, as are the Gromov products \( (x_{i_k}, x_{j_k})_e \). But this contradicts the hypothesis that \( \{x_j\}_{j \in \mathbb{N}} \) tends to infinity. \( \square \)

The compactification of the Rips complex described in Definition 2.2 also gives a compactification of the \((N + 1)\)–skeleton of the Rips complex.

**Proposition 3.10.** The map \( r : R^{(N+1)} \to \mathcal{X}(N) \) extends to a continuous map \( \overline{R}^{(N+1)} \to \overline{\mathcal{X}}(N) \) for all \( i \). This restricts to the identity on \( \partial(G, \mathcal{P}) \).

**Proof.** It suffices to show that if \( \{a_j\}_{j \in \mathbb{N}} \) is a sequence of points in \( R^{(N+1)} \) limiting to \( z \in \partial(G, \mathcal{P}) \) then \( \{r(a_j)\} \) also limits to \( z \).

For each \( j \), let \( v_j \) denote a vertex of a simplex containing \( a_j \). Suppose first that the \( r(a_j) \) have bounded depth. Then, \( d(r(a_j), r(v_j)) \) is bounded which implies \( r(a_j) \) approaches \( z \).

Suppose the \( r(a_j) \) have unbounded depth. For all but finitely many \( j \), \( r(a_j) \) and \( v_j \) will be in the same horoball so Lemma 3.9 implies that \( r(a_j) \) and \( v_j \) converge to the same boundary point. \( \square \)

Now we prove the main proposition of the section.

**Proposition 3.11.** For each \( i = 0, \ldots, N \), every \( z \in \partial(G, \mathcal{P}) \) and every neighborhood \( U \) of \( z \) in \( \overline{\mathcal{X}}(N) \), there is a neighborhood \( V \subseteq U \) of \( z \) such that every map \( S^i \to V \setminus \partial(G, \mathcal{P}) \) is nullhomotopic in \( U \setminus \partial(G, \mathcal{P}) \).

**Proof.** Given a neighborhood \( U \subseteq \overline{\mathcal{X}}(N) \) of \( z \), let \( v(U) \) be the set of vertices whose closed stars are contained in \( U \), let \( U_1 \) be the interior of the full subcomplex on the vertices \( v(U) \), and let \( \hat{U}_1 = U_1 \cup (U \cap \partial(G, \mathcal{P})) \). Then we claim \( \hat{U}_1 \subseteq U \) is still an open neighborhood of \( z \) in \( \mathcal{X}(N) \). The intersection with \( \mathcal{X}(N) \) is open by construction so we just need to check \( \hat{U}_1 \) contains an open neighborhood of any \( w \in U \cap \partial(G, \mathcal{P}) \). Suppose there is a sequence \( \{x_i\}_{i \in \mathbb{N}} \) of vertices of \( \mathcal{X}(N) \setminus U_1 \) which converges to \( w \in U \cap \partial(G, \mathcal{P}) \). All but finitely many of these vertices is in \( U \setminus U_1 \), so all but finitely many of these vertices have closed stars which meet \( \mathcal{X}(N) \setminus U \). In particular there is a sequence of vertices \( \{x'_i\}_{i \in \mathbb{N}} \) outside \( U \), but converging to \( w \), contradicting our choice of \( U \).

Let \( r \) be as in Lemma 3.8 and let \( \iota = \iota_{N+2} : \mathcal{X}(N) \to R^{(N+2)} \) be the inclusion of \( \mathcal{X}(N) \) as a subcomplex of the Rips complex.

Then \( r^{-1} (\hat{U}_1) \) is an open subset of \( \overline{R}^{(N+1)} \). By Proposition 2.4, there is a neighborhood \( W \subseteq r^{-1} (U_1) \) of \( z \) such that spheres of dimension up to \( N \) in \( W \setminus \partial(G, \mathcal{P}) \) are contractible in \( r^{-1} (U_1) \setminus \partial(G, \mathcal{P}) \).

Let \( v(W) \) be the set of vertices of \( W \) whose closed stars in \( R^{(N+1)} \) are contained in \( W \). Let \( W_1 \) be the interior of the full subcomplex of \( R^{(N+2)} \) on the vertices \( v(W) \), and let \( \hat{W}_1 = W_1 \cup (W \cap \partial(G, \mathcal{P})) \). A similar argument to that in the first paragraph shows that \( \hat{W}_1 \) is an open neighborhood of \( z \) in \( R^{(N+2)} \).

Let \( v' = r^{-1}(W) \), let \( V_1 \) be the interior of the subcomplex of \( \mathcal{X}(N) \) made of cells whose closed stars are in \( V' \), and let \( \hat{V}_1 = V_1 \cup (W \cap \partial(G, \mathcal{P})) \). Arguing again as in the first paragraph, \( V \) is still an open neighborhood of \( z \) in \( \mathcal{X}(N) \).

We establish that \( V \subseteq U \). Indeed, \( U \) contains the full subcomplex in \( \mathcal{X}(N) \) spanned by \( W \cap \mathcal{X}(N)^{(0)} \). This subcomplex contains the intersection of \( W_1 \) with \( \mathcal{X}(N) \) in \( R^{(N+2)} \), which is \( V' \). Thus \( V \subseteq U \).

Next we show that maps from \( S^i \) into \( V \setminus \partial(G, \mathcal{P}) \) are null-homotopic in \( U \setminus \partial(G, \mathcal{P}) \). Let \( \alpha : S^i \to V \setminus \partial(G, \mathcal{P}) \). We can homotope \( \alpha \) in \( V \) to have image in the \( i \)–skeleton of \( V' = r^{-1}(W_1) \). Let \( \iota_{N+1} : \mathcal{X}(N)^{(N+1)} \to R^{(N+1)} \) be as in Lemma 3.8. Then \( \iota_{N+1} \circ \alpha \) has image inside \( W \). Thus there is a homotopy \( h_t \) from \( \iota_{N+1} \circ \alpha \) to a constant, so that the homotopy occurs completely inside \( r^{-1}(U_1) \). Applying \( r \) to the homotopy, we get a homotopy \( r \circ h_t \) from \( \alpha \) to a constant occurring entirely inside \( U_1 \subseteq U \setminus \partial(G, \mathcal{P}) \). \( \square \)
3.3. A Z–set when \((G, \mathcal{P})\) is type \(F\). In this section we show that if \((G, \mathcal{P})\) is type \(F\), then \(\partial(G, \mathcal{P})\) gives an equivariant \(Z\)–set compactification of \(\mathcal{X}(N)\) for large \(N\). This fact isn’t needed for the proof of Theorem 1.1 but will be used in Sections 4 and 5.

We observe first that, assuming that \((G, \mathcal{P})\) has type \(F\), we may choose \(E_G\) and each \(E_P\) in \(3.2\) to be finite complexes, so that, for some \(N\) and all \(i \geq N\), \(\mathcal{X}(i) = \mathcal{X}(N)\). It follows that this space is contractible.

**Theorem 3.12.** If \((G, \mathcal{P})\) is relatively hyperbolic and type \(F\), and \(\mathcal{X}(N)\) is chosen as above, then \(\partial(G, \mathcal{P})\) is a \(Z\)–set in \(\overline{\mathcal{X}(N)}\).

In general, it is difficult to verify that a closed subset is a \(Z\)–set. To do this, we will use the following from [BM91].

**Proposition 3.13.** [BM91, Proposition 2.1] Suppose \(X\) is compact metrizable and that \(F \subseteq X\) is closed such that the following conditions are satisfied.

1. \(F\) has empty interior in \(X\)
2. \(\dim X = n < \infty\)
3. For each \(i = 0, 1, \ldots, n\), every \(z \in F\) and every neighborhood \(U\) of \(z\), there is a neighborhood \(V \subseteq U\) of \(z\) such that a map \(S^i \to V \setminus F\) is nullhomotopic in \(U \setminus F\)
4. \(X \setminus F\) is an ANR

Then, \(X\) is an ANR and \(F \subseteq X\) is a \(Z\)-set.

Before we prove Theorem 3.12 we need the following consequence of a result of Dahmani.

**Lemma 3.14.** For any relatively hyperbolic pair \((G, \mathcal{P})\), the dimension of \(\partial(G, \mathcal{P})\) is finite.

**Proof.** The proof of [Dah03, Lemma 3.7] shows that the Gromov boundary of the coned-off Cayley graph is finite dimensional. Since \(\partial(G, \mathcal{P})\) is the union of the boundary of the coned-off Cayley graph with a countable set, \(\partial(G, \mathcal{P})\) is finite dimensional. \(\square\)

We now prove Theorem 3.12.

**Proof.** We verify that the hypotheses of Proposition 3.13 hold for \(\partial(G, \mathcal{P}) \subseteq \overline{\mathcal{X}(N)}\). The first and fourth conditions are clear. Lemma 3.14 shows that \(\partial(G, \mathcal{P})\) is finite dimensional, so \(\overline{\mathcal{X}(N)}\) is also finite dimensional. The third condition follows from Proposition 3.11 and the fact that \(\mathcal{X}(N)\) is contractible when \((G, \mathcal{P})\) is type \(F\). \(\square\)

3.4. A \(Z_{N−1}\)–set otherwise. We return to the setting in which \((G, \mathcal{P})\) is assumed only to be \(F_{\infty}\) and not type \(F\). In the papers [GS73, GS74], Geoghegan and Summerhill propose the notion of a \(Z_k\)–set.

**Definition 3.15.** A closed subset \(F\) of a space \(X\) is a \(Z_k\)–set if, for every nonempty \(k\)–connected open \(U \subseteq X\), the set \(U \setminus F\) is also nonempty and \(k\)–connected.

Bestvina and Mess’s proof of Proposition 3.13 in [BM91] gives the following weaker result that will be important when working with \(F_{\infty}\) groups.

**Proposition 3.16.** Suppose \(X\) is compact metrizable and \(F \subseteq X\) is closed. Suppose conditions (1) and (4) of Proposition 3.13 are satisfied and that condition (3) holds for some \(n\). Then,

1. [BM91, Lemma 2.4] Let \(P\) be a finite simplicial complex of dimension \(\leq n\), and let \(f: P \to X\) be a map. Then there is a homotopy \(h: P \times I \to X\) so that \(h(-,0) = f\) and \(h(-,t)\) has image in \(X \setminus F\) for all \(t > 0\).
2. [BM91, Lemma 2.5] For each \(i = 0, 1, \ldots, n\), each \(z \in F\) and each neighborhood \(U\) of \(z\), there is a neighborhood \(V \subseteq U\) of \(z\) such that every map \(S^i \to V\) is nullhomotopic in \(U\).
The second part of Proposition 3.19 differs from Proposition 3.11 in that the spheres under consideration are allowed to meet the boundary.

The first part of Proposition 3.16 implies that $F \subseteq X$ is a $\mathbb{Z}_{n-1}$-set. Indeed, suppose that $U$ is $(n-1)$-connected, and that $f_0 : S^i \to U \setminus F$ is any map, where $i \leq (n-1)$. Take $P = S^i \times I$, and let $f : P \to U$ be a null-homotopy of $f$. Now apply the first part of Proposition 3.16 to obtain $h$. For some small $\epsilon$, $h|_{P \times (0,\epsilon]}$ has image contained in $U \setminus F$, and thus gives a null-homotopy of $P$ in $U$ which misses $F$.

Using Proposition 3.11 and Lemma 3.14 as in the proof of Theorem 3.12 we obtain the following.

**Corollary 3.17.** The Bowditch boundary $\partial(G;\mathcal{P})$ is a $\mathbb{Z}_{N-1}$-set in $\overline{\mathcal{X}(N)} = \mathcal{X}(N) \cup \partial(G;\mathcal{P})$.

### 3.5. Vanishing of Čech cohomology of the compactification.

**Lemma 3.18.** Suppose $V \to U$ factors as

$$V = V_n \to V_{n-1} \to \cdots \to V_0 \to U$$

where each map induces the trivial homomorphism on $\pi_i$ for $i \leq n$. Then, the induced homomorphism $H_i(V;\mathbb{Z}) \to H_i(U;\mathbb{Z})$ is trivial for $i \leq n$.

**Proof.** The map $V_n \to V_{n-1}$ factors through a connected space, which we will denote $W_0$. The map $W_0 \to V_{n-2}$ factors through a simply connected space $W_1$. Proceeding inductively, we see that $V_n \to U$ factors through an $n$-connected space $W_n$, so the map is trivial on homology. \(\square\)

The following is the key lemma:

**Lemma 3.19.** For $k \leq N$, $\check{H}^k(\overline{\mathcal{X}(N)};A) \cong 0$ where the left hand side is reduced Čech cohomology.

**Proof.** We claim that $\overline{\mathcal{X}(N)}$ is $HLC^N$. For this, we only need to consider the points on $\partial(G;\mathcal{P})$. Let $z \in \partial(G;\mathcal{P})$ and let $U$ be an open neighborhood of $z$ in $\overline{\mathcal{X}(N)}$. We need an open neighborhood $V \subseteq U$ of $z$ such that $H_i(V;\mathbb{Z}) \to H_i(U;\mathbb{Z})$ is trivial for $i = 0, \ldots, N$. By Propositions 3.11 and 3.16 we see that there is a neighborhood $V_0 \subseteq U$ of $z$ such that maps $S^i \to V_0$ are nullhomotopic in $U$ for $i = 0, \ldots, N$. Inductively, we can find $V_j \subseteq V_{j-1}$ such that maps $S^i \to V_j$ are nullhomotopic in $V_{j-1}$. Applying Lemma 3.18, we see that $\overline{\mathcal{X}(N)}$ is $HLC^N$.

By (2.14) there is the isomorphism $H^i(\overline{\mathcal{X}(N)};A) \cong H^i(\mathcal{X}(N);A)$ between Čech cohomology and singular cohomology for $i \leq N$. Now, we show that $\overline{\mathcal{X}(N)}$ is $N$-connected. Consider a map $f : S^i \to \overline{\mathcal{X}(N)}$. By Proposition 3.16 we may assume that $f(S^i) \cap \partial(G;\mathcal{P}) = \emptyset$. Then $f$ is nullhomotopic because $\mathcal{X}(N)$ is $N$-connected. So $H_i(\overline{\mathcal{X}(N)};\mathbb{Z}) \cong 0$ for $i \leq N$ and, by the universal coefficients theorem, $H^i(\overline{\mathcal{X}(N)};A) \cong 0$ for $0 < i \leq N$. Therefore, $H^i(\overline{\mathcal{X}(N)};A) \cong 0$ for $0 < i \leq N$. The $i = 0$ case is trivial since we are using reduced Čech cohomology. \(\square\)

We can now relate the compactly supported cohomology of $\mathcal{X}(N)$ with the Čech cohomology of the Bowditch boundary.

**Proposition 3.20.** For $k \leq N - 1$ there is an isomorphism of $AG$-modules

$$H^k_c(\mathcal{X}(N);A) \to \check{H}^{k-1}(\partial(G;\mathcal{P});A).$$

**Proof.** Since $\overline{\mathcal{X}(N)} = \mathcal{X}(N) \cup \partial(G;\mathcal{P})$ is compact Hausdorff, and $\partial(G;\mathcal{P})$ is closed in $\overline{\mathcal{X}(N)}$, (Bre97 II.10.3) gives the following long exact sequence of sheaf cohomology groups.

$$\cdots \to H^{k-1}(\overline{\mathcal{X}(N)};A) \to H^{k-1}(\partial(G;\mathcal{P});A) \to H^k_c(\mathcal{X}(N);A) \to H^k(\overline{\mathcal{X}(N)};A) \to \cdots$$

The space $\mathcal{X}(N)$ is a CW-complex, so its compactly supported sheaf cohomology is isomorphic to its compactly supported singular cohomology (see Appendix, Proposition A.6). Additionally, sheaf cohomology is isomorphic to Čech cohomology for the spaces above. The result follows from Lemma 3.19. \(\square\)
3.6. Proof of Theorem 1.1. Recall the statement.

**Theorem 1.1.** If \((G, \mathcal{P})\) is relatively hyperbolic and type \(F_\infty\), then for every \(k\), there is an isomorphism of \(AG\)-modules

\[
H^k(G, \mathcal{P}; AG) \to H^{k-1}(\partial(G, \mathcal{P}); A).
\]

**Proof.** We fix a \(k\) and establish the isomorphism (1). Fix some \(N\) so that \(N \geq k + 1\) and consider the \(N\)-connected space \(\mathcal{X}(N)\) defined in Definition 3.2. This space is an \((N+2)\)-dimensional locally finite complex, so it is locally compact and locally contractible. Define \(E\) to be the full subcomplex on the vertices of depth \(\leq 1\), and let \(V\) be the full subcomplex on the vertices of depth exactly 1.

Consider the short exact sequence of simplicial cochains with compact support:

\[
0 \to C^*_c(E, V; A) \to C^*_c(E; A) \to C^*_c(V; A) \to 0
\]

Here, \(C^*_c(E, V; A)\) is defined to be the kernel of the restriction \(C^*_c(E; A) \to C^*_c(V; A)\).

By construction, the space \(E \setminus V\) is homeomorphic to \(\mathcal{X}(N)\). By Theorem [A.9] the cohomology of \(C^*_c(E, V; A)\) is \(H^*_c(\mathcal{X}(N); A)\).

By \([Bro82\text{ Lemma VIII.7.4}]\) the compactly supported simplicial cochain complexes \(C^*_c(E; A)\) and \(C^*_c(V; A)\) are naturally isomorphic as \(AG\) modules to the complexes \(\text{Hom}_G(C_*(E), AG)\) and \(\text{Hom}_G(C_*(V), AG)\), respectively. (Brown assumes \(A = \mathbb{Z}\) in the statement, but the proof goes through for an arbitrary ring.) Because the isomorphism is natural, there is a map of \(AG\)-modules such that the following diagram commutes:

\[
\begin{array}{ccc}
0 & \to & C^*_c(E, V; A) \to C^*_c(E; A) \to C^*_c(V; A) \to 0 \\
\downarrow & & \downarrow & & \downarrow \\
0 & \to & \text{Hom}_G(C_*(E, V); AG) \to \text{Hom}_G(C_*(E); AG) \to \text{Hom}_G(C_*(V); AG) \to 0
\end{array}
\]

For \(j \leq N\), the \(j\)-th cohomology of \(\text{Hom}_G(C_*(E, V), AG)\) is \(H^j(G, \mathcal{P}; AG)\) by an application of Proposition 2.18. Using the Five Lemma, we deduce

\[
H^j_c(\mathcal{X}(N); A) \cong H^j(G, \mathcal{P}; AG), \text{ when } j \leq N.
\]

All that remains is to identify \(H^k_c(\mathcal{X}(N); A)\) with \(H^{k-1}(\partial(G, \mathcal{P}); A)\). But this is the content of Proposition 3.20. \(\square\)

We record the following consequence of the proof of Theorem 1.1 which will be used in the proof of Lemma 4.15.

**Addendum 3.21.** With the same assumptions and notation as in 1.1, there is the following diagram where the vertical arrows are isomorphisms of \(AG\)-modules.

\[
\begin{array}{cccc}
\cdots & \to & H^{N-1}_c(V; A) & \to & H^N_c(E, V; A) & \to & H^N_c(E; A) & \to & H^N_c(V; A) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
\cdots & \to & H^{N-1}(\mathcal{P}; AG) & \to & H^N(G, \mathcal{P}; AG) & \to & H^N(G; AG) & \to & H^N(\mathcal{P}; AG)
\end{array}
\]

We now prove a corollary alluded to in the introduction.

**Corollary 3.22.** If \((G, \mathcal{P})\) is an \(F_\infty\) relatively hyperbolic group pair, then there is an \(N > 0\) such that, for all \(k \geq N\),

\[
H^k(G; ZG) \cong H^k(\mathcal{P}; ZG) \cong \oplus_{P \in \mathcal{P}} H^k(P; ZP) \otimes_{ZP} ZG
\]

**Proof.** The first isomorphism follows from the long exact cohomology sequence of a group pair and the fact that \(\partial(G, \mathcal{P})\) is finite dimensional (Lemma 3.14). The second isomorphism follows from \([Bro82\text{ Exercise VIII.5.4a}]\). \(\square\)
4. Boundaries of PD($n$) pairs.

A PD($n$) group pair $(G, \mathcal{P})$ is a pair which is FP and for which

$$H^k(G, \mathcal{P}; \mathbb{Z}G) \cong \begin{cases} \mathbb{Z} & k = n \\ 0 & k \neq n \end{cases}$$

where $\mathbb{Z}$ is the abelian group $\mathbb{Z}$ with a possibly nontrivial action of $G$.

A thorough discussion of PD($n$) pairs can be found in [BE78]. The following two results are easily deduced from Theorems 2.1, 4.2, and 6.2 of that paper.

**Theorem 4.1.** For a PD($n$) pair $(G, \mathcal{P})$ and a $\mathbb{Z}G$-module $M$, there is a commutative ladder between long exact sequences where the vertical arrows are isomorphisms:

$$\cdots \to H^k(G; M) \to H^k(\mathcal{P}; M) \to H^{k+1}(G, \mathcal{P}; M) \to \cdots \quad \text{long exact sequence}$$

**Proposition 4.2.** If $(G, \mathcal{P})$ is a PD($n$) pair and $P \in \mathcal{P}$, then $P$ is a PD($n-1$) group. In particular,

$$H^k(P; \mathbb{Z}P) \cong \begin{cases} \mathbb{Z} & k = n - 1 \\ 0 & k \neq n - 1 \end{cases}$$

The main result of this section is the following.

**Theorem 1.3.** Suppose $(G, \mathcal{P})$ is relatively hyperbolic and type $F$. The following are equivalent:

1. $(G, \mathcal{P})$ is a PD($n$) pair.
2. $\partial(G, \mathcal{P})$ is a homology $(n-1)$–manifold and an integral Čech cohomology $(n-1)$–sphere.

Since 2-dimensional homology manifolds are manifolds [Wil63 IX.5.6], we recover the following result of Tshishiku and Walsh [TW17].

**Corollary 4.3.** Suppose $(G, \mathcal{P})$ is type $F$ and relatively hyperbolic. The pair $(G, \mathcal{P})$ is PD(3) if and only if $\partial(G, \mathcal{P}) \cong S^2$.

**Remark.** In [Bes96], Bestvina considers groups which are PD($n$) over arbitrary principal ideal domains and he uses a “cell-trading argument” in his proof of [Bes96 Proposition 2.7]. Because we do not have a cocompact action, we cannot mimic this argument. So, we appeal to the Eilenberg-Ganea Theorem which restricts our statements to integer coefficients.

For the remainder of this section we assume that $(G, \mathcal{P})$ is a type $F$ relatively hyperbolic pair, and $\mathcal{X} = \mathcal{X}(N)$ where $N$ is large enough so that $\mathcal{X}(N)$ is contractible. Additionally, we will suppress integer coefficients. We note the following corollary of Theorem 1.1 and [BE78 Theorem 6.2].

**Corollary 4.4.** Suppose $(G, \mathcal{P})$ is type $F$ and relatively hyperbolic. Then $(G, \mathcal{P})$ is PD($n$) if and only if $\partial(G, \mathcal{P})$ is a Čech cohomology $(n-1)$–sphere.

The remainder of this section is therefore devoted to showing that if $(G, \mathcal{P})$ is PD($n$), then $\partial(G, \mathcal{P})$ is a homology $(n-1)$–manifold. In outline, we follow the proof of [Bes96 Theorem 2.8]. The chief difference is that the cellular chain complex of $\mathcal{X}$ is not finitely generated as a $\mathbb{Z}G$–module.

The case of PD(2) pairs is well understood by work of Eckmann-Müller (covering the case that $\mathcal{P} \neq \emptyset$) and Eckmann-Linnell (covering the absolute case).

**Theorem 4.5.** [EM80 4.3] [PL83 Theorem 2] If $(G, \mathcal{P})$ is PD(2), then $G = \pi_1 \Sigma$ for some compact surface. If $\mathcal{P}$ is empty, $\Sigma$ is closed, and otherwise the elements of $\mathcal{P}$ are the fundamental groups of the boundary components of $\Sigma$. 
If such a pair is relatively hyperbolic, its Bowditch boundary is $S^1$. We can therefore make the following assumption:

**Assumption 4.6.** $n \geq 3$.

**Proposition 4.7.** If $(G, \mathcal{P})$ is a PD$(n)$ pair, we can assume the complex $\mathcal{X}$ is $n$–dimensional.

**Proof.** As explained in [BE78], both $G$ and each $P \in \mathcal{P}$ are $(n-1)$–dimensional duality groups. Each $P \in \mathcal{P}$ is moreover a PD$(n-1)$ group. In particular $G$ has cohomological dimension $n$, and by the Eilenberg-Ganea Theorem admits a classifying space (which we can assume is simplicial) $B_G$ with $\dim(B_G) = \max\{3, n-1\}$. Thus the cocompact part of $\mathcal{X}$ is at most $n$–dimensional.

We claim that each $P \in \mathcal{P}$ has a classifying space of dimension $(n-1)$. If $n \geq 4$, this follows from Eilenberg-Ganea. If $n = 3$, then it follows from Theorem 4.5. It follows that the horoballs of $\mathcal{X}$ can be taken to be $n$–dimensional as well. □

We are therefore justified in making the following:

**Assumption 4.8.** $\mathcal{X}$ is $n$–dimensional.

We note the following corollary (this also follows from Theorem 5.1).

**Corollary 4.9.** The topological dimension of $\partial(G, \mathcal{P})$ is $n - 1$.

**Proof.** By Theorem 3.12 of [BM91] (see [GT13] for an alternate proof), the dimension of $\partial(G, \mathcal{P})$ is strictly less than the dimension of $\mathcal{X}$, so $\dim(\partial(G, P)) \leq n - 1$. On the other hand Theorem 1.1 gives $H^{n-1}(\partial(G, P)) \cong H^n(G, P; \mathbb{Z}G) \cong \mathbb{Z} \neq 0$, so $\dim(\partial(G, P)) \geq n - 1$. □

If $G$ acts nontrivially on $\tilde{\mathcal{X}}$ it has an index 2 subgroup $H$ which does act trivially. Let $\mathcal{P}_H$ be the induced peripheral structure on $H$ (Definition 2.11). Then $(H, \mathcal{P}_H)$ is relatively hyperbolic, with the same Bowditch boundary as $(G, \mathcal{P})$, by Lemma 2.12. Moreover, $(G, \mathcal{P}_H)$ is a PD$(n)$ pair with trivial action on $H^n(H, \mathcal{P}_H; \mathbb{Z}H)$ by [BE78] Theorem 7.6. So, to prove Theorem 1.3 it suffices to prove the theorem in the case that $\tilde{\mathcal{X}}$ has a trivial $G$–action.

**Assumption 4.10.** $\tilde{\mathcal{X}}$ has a trivial $G$–action.

**Remark.** Let $M$ be equal either to the $k$–chains of $\mathcal{X}$ or the $k$–cochains of compact support. Then for each $m \in M$ there is a well-defined support of $m$ in $\mathcal{X}$:

- If $M$ is the $k$–chains, and $m = \sum \lambda_i \sigma_i$ is an expression as a sum of simplices, $\text{supp}(m) = \cup \{\sigma_i \mid \lambda_i \neq 0\}$.
- If $M$ is the compactly supported $k$–cochains, and $m \in M$, then $\text{supp}(m) = \cup \{\sigma \mid m(\sigma) \neq 0\}$.

Supports have the following nice properties:

1. For each $g \in G$, $m \in M$, $\text{supp}(gm) = g \cdot \text{supp}(g)$.
2. For any $m, n \in M$, $\text{supp}(m + n) \subset \text{supp}(m) \cup \text{supp}(n)$.

We will refer to such an $M$ as a $G$–module with supports in $\mathcal{X}$.

**Definition 4.11.** Let $M$ and $N$ be $G$–modules with supports in $\mathcal{X}$. A function $f : M \to N$ has bounded displacement if there is a number $R > 0$ so that, for all $m \in M$, $\text{supp}(f(m))$ is contained in a cellular $R$–neighborhood of $\text{supp}(m)$. If we need to be specific about $R$ we say that $f$ has displacement bounded by $R$.

For example, the cellular boundary and coboundary maps have bounded displacement, with displacement bounded by 1.

The following is an adaptation of a definition from [Bes96].
**Definition 4.12.** Suppose that \( C = \{ \cdots \to C_{i+1} \xrightarrow{\partial} C_i \to \cdots \} \) is a finite length chain complex of \( G \)-modules with supports in \( \mathcal{X} \). We say \( C \) is regular if, for every \( z \in \partial(G, \mathcal{P}) \), and every open neighborhood \( U \subset \mathcal{X} \) of \( z \), there is a smaller open neighborhood \( V \) so that whenever \( c \) is an \( i \)-boundary with \( \text{supp}(c) \subset V \), then \( c = \partial d \) for some \( d \) with \( \text{supp}(d) \subset U \).

The following lemma doesn’t depend on \( \dim \mathcal{X} = n \).

**Lemma 4.13.** The cellular chain complex of \( \mathcal{X} \) is regular.

**Proof.** Let \( z \in \partial(G, \mathcal{P}) \). We will denote a subset of \( \bar{\mathcal{X}} \) as \( \bar{\mathcal{S}} \) and we will denote its intersection with \( \mathcal{X} \) as \( \mathcal{S} \). Letting \( \bar{U} \) be an arbitrary neighborhood of \( z \), we can take \( \bar{W} \subset \bar{U} \) such that there is a subcomplex \( L \) of \( \mathcal{X} \) with \( W \subset L \subset U \). We can also take \( \bar{V} \) such that the inclusion \( V \hookrightarrow W \) induces the trivial homomorphism on \( H_i \) for \( i \leq n \). This follows from using Proposition 3.11 to obtain open sets \( \bar{V}_n \subset \bar{V}_{n-1} \subset \cdots \subset \bar{U} \) with each \( V_i \hookrightarrow V_{i-1} \) inducing the trivial map on \( \pi_i \) for \( i \leq n \) and applying Lemma 3.18. Now, if we have a cellular cycle supported in \( \bar{V} \), it must be bounded by a chain in \( L \). \( \square \)

### 4.1. Regularity of Cochains

In this subsection, we prove that the complex of simplicial cochains with compact support of \( \mathcal{X} \) is regular. The proof relies on comparing the cochains with compact support to the chains and controlling the differentials. We will adopt the following conventions for the remainder of this section.

**Notation 4.14.** Unless stated otherwise, \( M \) will be either \( C_i(\mathcal{X}) \) or \( C_i^{\text{cm}}(\mathcal{X}) \) (the simplicial chains and cochains with compact support) and maps will be homomorphisms of \( \mathbb{Z}G \)-modules. \( \tilde{Y}_P \times [0, \infty) \) is a horoball in \( \mathcal{X} \) corresponding to the subgroup \( P \). We will use \( (C_*, d) \) to denote the chain complex \( (C_*(\mathcal{X}), \partial) \) or \( (C_\text{cm}^n(\mathcal{X}), \delta) \). When using \( (C_*, d) \), we will call elements in the image of \( d \) “boundaries” even though they may be coboundaries. Similarly, we will call elements in the kernel of \( d \) “cycles” even though they may be cocycles. Let \( j > 0 \) be an integer. We will use \( \mathcal{X}_{\leq j} \) and \( \mathcal{X}_{< j} \) to denote the subspace of depth at most \( j \) and the subspace of depth less than \( j \). Similarly, \( \mathcal{X}_{\geq j} \) and \( \mathcal{X}_{> j} \) will denote the subspace of depth at least \( j \) and the subspace of depth greater than \( j \). We will use \( \mathcal{X}_j \) to denote the subspace of depth \( j \).

**Lemma 4.15.** The inclusion \( (j, \infty) \times E_P \to \mathcal{X} \) induces isomorphisms on \( H_\text{cm}^* \) and \( H_* \).

**Proof.** The case for \( H_* \) is trivial. For \( H_\text{cm}^* \) we make heavy use of the long exact sequences from Theorem A.8 in the Appendix.
We will describe arrows which make the following diagram commute, such that all vertical arrows are isomorphisms.

\[
\begin{array}{ccccccccc}
0 & \rightarrow & H^{n-1}_c(\mathcal{X}_{\leq j}) & \rightarrow & H^n_c(\mathcal{X}_{\leq j}) & \rightarrow & H^n_c(\mathcal{X}) & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \rightarrow & H^{n-1}_c(\mathcal{X}_{\leq j}) & \rightarrow & H^{n-1}_c(\mathcal{X}_j) & \rightarrow & H^n_c(\mathcal{X}_{\leq j}) & \rightarrow & 0 \\
\end{array}
\]

(2)

\[
\begin{array}{cccccc}
0 & \rightarrow & H^{n-1}(G;\mathbb{Z}G) & \rightarrow & H^{n-1}(\mathcal{P};\mathbb{Z}G) & \rightarrow & H^n(G;\mathcal{P};\mathbb{Z}G) & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \rightarrow & H_1(G;\mathcal{P};\mathbb{Z}G) & \rightarrow & H_0(\mathcal{P};\mathbb{Z}G) & \rightarrow & H_0(G;\mathbb{Z}G) & \rightarrow & 0 \\
\end{array}
\]

The first row is from the long exact sequence given by the pair \((\mathcal{X}, \mathcal{X}_{\leq j})\) and second row is from the long exact sequence given by the pair \((\mathcal{X}_{\leq j}, \mathcal{X}_j)\).

We next choose isomorphisms \(\Phi\) and \(\Psi\) so that the top right square in the diagram commutes. Then there will exist a unique isomorphism at the top left completing that commutative square. By considering the pair \((\mathcal{X}, \mathcal{X}_j)\) we obtain the exact sequence

\[
0 \rightarrow H^{n-1}_c(\mathcal{X}_j) \rightarrow H^n_c(\mathcal{X}_{\leq j} \cup \mathcal{X}_j) \rightarrow H^n_c(\mathcal{X}) \rightarrow 0
\]

(3)

Since \(H^n_c(\mathcal{X}_{\leq j} \cup \mathcal{X}_j) \cong H^n_c(\mathcal{X}_{\leq j}) \oplus H^n_c(\mathcal{X}_j)\) there are maps \(p_1\) and \(p_2\) projecting onto the summands and sections \(\iota_1\) and \(\iota_2\). We obtain maps \(H^{n-1}_c(\mathcal{X}_j) \rightarrow H^n_c(\mathcal{X})\) which factor through \(H^n_c(\mathcal{X}_{\leq j})\) and \(H^n_c(\mathcal{X}_j)\) by taking \(-f \circ \iota_1 \circ p_1 \circ \delta\) and \(f \circ \iota_2 \circ p_2 \circ \delta\). Note that \(p_1 \circ \delta\) agrees with the map \(H^{n-1}_c(\mathcal{X}_j) \rightarrow H^n_c(\mathcal{X}_{\leq j})\) in the second row of (2). We define \(\Psi = -f \circ \iota_1\). The long exact sequence for \((\mathcal{X}, \mathcal{X}_{\geq 2})\) together with Corollary \([A.10]\) shows that \(f \circ \iota_1\) is an isomorphism, so \(\Psi\) is also an isomorphism.

Similarly we define \(\Phi = p_2 \circ \delta\). The long exact sequence for \((\mathcal{X}_{\geq 2}, \mathcal{X}_j)\) together with Corollary \([A.10]\) shows that \(\Phi\) is an isomorphism. The composition \(f \circ \iota_2\) agrees with the map \(H^n_c(\mathcal{X}_{\geq 2}) \rightarrow H^n_c(\mathcal{X})\) in the top row of the diagram. By exactness of (3), we have that \(f \circ \iota_1 \circ p_1 \circ \delta + f \circ \iota_2 \circ p_2 \circ \delta = 0\) so the square in the top right hand corner of (2) commutes.

The middle vertical arrows are isomorphisms from \([3.21]\).

The bottom vertical arrows are the isomorphisms from Theorem \([4.1]\).

Since the bottom row is isomorphic to the short exact sequence

\[
0 \rightarrow \Delta \rightarrow \mathbb{Z}G/\mathcal{P} \rightarrow \mathbb{Z} \rightarrow 0
\]

so is the top row.

The inclusion of a component \((j, \infty) \times E_P \hookrightarrow \mathcal{X}_{\geq j}\) induces the inclusion of a \(\mathbb{Z}\) summand into \(\mathbb{Z}G/\mathcal{P}\) so \(H^*_c((j, \infty) \times E_P) \rightarrow H^n_c(\mathcal{X}_{\geq j}) \rightarrow H^n_c(\mathcal{X})\) is an isomorphism. \(\square\)

Lemma \([4.15]\) is about singular homology and singular cohomology with compact supports but we would like to work with simplicial chains and cochains. Fix a homeomorphism \(\rho: \mathbb{R} \rightarrow (0, \infty)\) which restricts to the identity on \([1, \infty)\). Now, for each \(P \in \mathcal{P}\), give \(\mathbb{R} \times E_P\) a \(\mathbb{Z} \times \mathcal{P}\)-equivariant simplicial structure so that \((\rho, 1_{E_P})|_{(1, \infty) \times E_P}\) is a simplicial inclusion into \(\mathcal{X}\). Extending \(G\)-equivariantly, we get a simplicial structure on all of \(\mathcal{X}_{>0}\).

Let \(C_{i,\Delta}\) denote simplicial chains and let \(C_{i,\sigma}\) denote singular chains. Consider the following maps, where the first and third maps are the inclusions of the simplicial chains into singular chains and the middle map is induced by the inclusion \(\mathcal{X}_{>0} \hookrightarrow \mathcal{X}\).

\[
C_{i,\Delta}(\mathcal{X}_{>0}) \rightarrow C_{i,\sigma}(\mathcal{X}_{>0}) \rightarrow C_{i,\sigma}(\mathcal{X}) \leftarrow C_{i,\Delta}(\mathcal{X})
\]

(4)

A simplicial chain in \(C_{i,\Delta}(\mathcal{X}_{>0})\) with support in \(\mathcal{X}_{\geq 1}\) will get mapped to a chain in the image of \(C_{i,\Delta}(\mathcal{X})\), allowing us to identify it with a simplicial chain in \(\mathcal{X}\). There are similar maps on cochains with compact support.
Thus, there is an element making the triangle commute.

**Lemma 4.15.** Suppose we have the following diagram.

\[
\begin{array}{ccc}
M & \xrightarrow{f'} & C_j \\
\downarrow{d} & & \downarrow{d} \\
C_j & \xrightarrow{d} & C_{j-1}
\end{array}
\]

Suppose that the image of \(f'\) is contained in the image of \(d\). If \(f'\) has bounded displacement, then there is an map \(f : M \to C_j\) of bounded displacement making the diagram commute.

**Proof.** Let \(e\) be a basis element of \(M\) (i.e., a simplex or dual simplex). Since \(f'\) has bounded displacement, \(f'(e)\) lies in a horoball \([1, \infty) \times E_P\) for all but finitely many \(e\). Also, \(f'(e)\) is a boundary by hypothesis.

We can identify \(f'(e)\) with a cycle in \(\mathbb{R} \times E_P\), using the identification described in the text before the lemma. Then, Lemma 4.15 implies that the maps in (4) induce isomorphisms on homology, as do the corresponding maps on cochains with compact support. In particular a cycle in \(X\) with support in \(X_{>0}\) is a boundary if and only if it is a boundary in \(X_{>0}\).

**Lemma 4.16.** Suppose there is a map \(f' : X \to C_j\) of bounded displacement making the diagram commute.

**Proof.** Let \(e\) be a basis element of \(M\) (i.e., a simplex or dual simplex). Since \(f'\) has bounded displacement, \(f'(e)\) lies in a horoball \([1, \infty) \times E_P\) for all but finitely many \(e\). Also, \(f'(e)\) is a boundary by hypothesis.

We can identify \(f'(e)\) with a cycle in \(\mathbb{R} \times E_P\), using the identification described in the text before the lemma. Then, Lemma 4.15 implies that \(f'(e)\) represents a boundary in \(X\) if and only if it represents a boundary in \((0, \infty) \times E_P \cong \mathbb{R} \times E_P\). Since \(f'\) has bounded displacement, there are only finitely many boundaries in \(\mathbb{R} \times E_P\) that can be identified with \(f'(e)\) up to the \(\mathbb{Z} \times P\)-action. Thus, there is a cycle \(g(e)\) supported in a cellular \(K\)-neighborhood of \(\partial f'(e)\).

By considering the \(e\) whose support has sufficiently large depth, we see that \(f'(e)\) is supported in \([K + 1, \infty) \times E_P\) for all but finitely many \(e\). For such \(e\), we can identify \(g(e)\) with an element of \(C_j\) and define \(f(e) = g(e)\). For the finitely many \(e\) that we have excluded, we can define \(f(e)\) to be any element making the triangle commute.

**Lemma 4.17.** There is a constant \(K\) such that, for every vertex \(v\) of \(X\), there exists a cocycle \(\varphi \in C^0_c(X)\) supported in a cellular \(K\)-neighborhood of \(v\) that represents a generator of \(H^1_c(X)\).

**Proof.** Suppose \(v\) has depth \(j\). Consider the map \((j, \infty) \times E_P \to X\) in Lemma 4.15 above. Let \(B\) denote the complement of the \((j, \infty) \times E_P\) and let \(\mathcal{H}\) denote \([j, \infty) \times E_P\) considered as a subcomplex of \(X\). There is the short exact sequence of (simplicial) cochain complexes.

\[
0 \to C^0_c(X) \to C^0_c(B) \oplus C^0_c(\mathcal{H}) \to C^0_c(E_P) \to 0
\]

Here, we are considering \(E_P\) as the subcomplex \(\{j\} \times E_P = B \cap \mathcal{H}\).
Because \((j, \infty) \times E_P \to X\) induces isomorphisms on cohomology with compact support, \(H^i_c(B)\) vanishes. Since \(H\) is a product with \([j, \infty)\), Corollary \([\text{Bes96}, \text{Proposition 2.7}]\) implies that \(H^c_2(H)\) also vanishes. Therefore, the coboundary map \(\delta : H^i_c(E_P) \to H^{i+1}_c(X)\) is an isomorphism. Now, fix a cocycle \(\psi\) that represents a generator of \(H^{n-1}_c(E_P)\). By translating via the action of \(P\), we can assume \(\psi\) is supported in a cellular \(K'\) neighborhood of \(v\) for some constant \(K'\) independent of \(v\).

We claim that a representative \(\varphi\) of \(\delta[\psi]\) can be chosen so that the assignment \(\psi \mapsto \varphi\) has bounded displacement. Indeed, let \((\psi, 0) \in C^{n-1}_c(B) \oplus C^{n-1}_c(H)\). Then, letting \(\varphi\) be the element mapping to \((\delta \psi, 0) \in C^n_c(B) \oplus C^n_c(H)\) gives the desired assignment. Because this assignment has bounded displacement, the result follows. \(\square\)

**Proposition 4.18.** The cellular cochain complex of \(X\) is regular.

**Proof.** We adapt the proof of \([\text{Bes96}, \text{Proposition 2.7}]\) to the space \(X\).

By Assumption \([\text{4.8}]\) \(\dim(X) = n\). Moreover the compactly supported cohomology of \(X\) is zero except in dimension \(n\), where it is \(\mathbb{Z}\). By Assumption \([\text{4.10}]\) the \(G\)-action on \(\mathbb{Z}\) is trivial.

By our assumptions we have \(H^n_c(X) = \mathbb{Z}\) when \(k = n\) and 0 otherwise. Moreover \(X\) is contractible. We therefore get free \(Z\) resolutions of \(\mathbb{Z}\),

\[
0 \longrightarrow C^n_c(X) \longrightarrow \cdots \longrightarrow C^n_c(X) \longrightarrow \mathbb{Z} \longrightarrow 0
\]

and

\[
0 \longrightarrow C_n(X) \longrightarrow \cdots \longrightarrow C_0(X) \longrightarrow \mathbb{Z} \longrightarrow 0.
\]

We construct chain maps \(f : C^{n-i}_c(X) \to C_i(X)\), \(g : C_i(X) \to C^{n-i}_c(X)\) and a homotopy \(h\) between \(g \circ f\) and the identity on \(C^*_c(X)\) such that each of these maps has bounded displacement.

We first define \(f\) on the natural basis of cochains dual to individual cells. Fix a generator \(e\) for \(H^n_c(X)\). Let \(e^*\) be the cochain dual to the \(n\)-simplex \(e\) (i.e. \(e^*(e) = 1\), but \(e^*(e') = 0\) for any cell \(e' \neq e\)). There are no \((n + 1)\)-cochains, so \(e^*\) is a cocycle, representing \(k(e)\alpha\) where \(k(e) \in \mathbb{Z}\). The \(n\)-simplex \(e\) is the image of an embedding from the standard simplex \(\Delta^n\) into \(X\). This standard simplex is the convex hull of the standard unit vectors \(v_0, \ldots, v_n \in \mathbb{R}^{n+1}\). Let \(p(e)\) be the vertex which is the image of \(v_0\). Define \(f_0(e^*) = k(e)p(e)\). Since the simplicial structure on \(X\) comes from a \(\Delta\)-complex structure on the quotient \(C = G\setminus X\), this defines a map of \(ZG\)-modules

\[
f_0 : C^n_c(X) \to C_0(X).
\]

The map \(f_0\) clearly has bounded displacement. Define \(f\) by applying Lemma \([\text{4.16}]\) inductively to the following diagram.

\[
\begin{array}{ccc}
C^{n-i}_c(X) & \xrightarrow{f_{i-1} \circ \delta} & C_i(X) \\
& \xrightarrow{\partial^{-1}} & C_{i-1}(X)
\end{array}
\]

By Lemma \([\text{4.17}]\) there is a constant \(K\) such that, for each vertex there is a cocycle representing \(1 \in H^n_c(X)\) supported in a \(K\)-neighborhood of the vertex. This allows us to define \(g_0 : C_0(X) \to C^n_c(X)\). Now \(g\) can be extended to a map of bounded displacement on \(C^n_c(X)\) by applying Lemma \([\text{4.16}]\) inductively to the following diagram.

\[
\begin{array}{ccc}
C_i(X) & \xrightarrow{g_{i-1} \circ \delta} & C^{n-i}_c(X) \\
& \xrightarrow{\delta} & C^{n-i+1}_c(X)
\end{array}
\]
For the homotopy, we need \( h\delta + \delta h = \text{Id} - g \circ f \). This can be done by setting the map \( Z \to C_c^*(\mathcal{X}) \) to be 0 and applying Lemma 4.16 to the following diagram.

\[
\begin{array}{ccc}
C_c^i(\mathcal{X}) & \xrightarrow{id - g \circ f - h\delta} & C_c^{i-1}(\mathcal{X}) \\
\delta & \rightarrow & C_c^i(\mathcal{X})
\end{array}
\]

There is some \( M > 0 \) so that all the maps \( f_i, g_i, \delta, \) and \( h \) have displacement bounded by \( M \).

Let \( z \in \partial(G, \mathcal{P}) \) and let \( U \) be an open neighborhood of \( z \) in \( \overline{X} \). Let \( W \) be the subcomplex of \( \mathcal{X} \) consisting of those simplices whose \( 3M \)-cellular neighborhoods are completely contained in \( U \), and let \( U_1 \) be the interior of \( W \).

Let \( V_i \subset U_1 \) be an open neighborhood of \( z \) so that every chain with support in \( V_i \) which is an \( \mathcal{X} \)-boundary is the boundary of a chain with support in \( U_1 \). Finally let \( V \subset V_i \) be a neighborhood of \( z \) so that the \( 3M \)-cellular neighborhood of every simplex of \( V \) is contained in \( V_i \).

Now suppose that \( b = \delta \varphi \) has support in \( V \), where \( \varphi \) is a simplicial \((k-1)\)-cochain in \( \mathcal{X} \). Then \( f(b) \) is a boundary with support in \( V_i \), so \( f(b) = \partial \sigma \) for a chain \( \sigma \) with support in \( U_1 \). We have \( \delta \varphi(\sigma) = g \circ f(b) = b - \delta hb \), so \( b = \delta g(\sigma) + h(b) \). Since \( \sigma \) and \( b \) both have support inside \( U_1 \), the cochain \( g(\sigma) + h(b) \) has support inside \( U \).

The following lemma is a rephrasing of Proposition 4.18.

**Lemma 4.19.** Let \( \{U_i\}_{i \in \mathbb{N}} \) be a neighborhood basis of \( z \in \overline{X} \) such that \( \mathcal{X} \setminus U_i \) is a subcomplex for each \( i \). Let \( U_i = \bar{U}_i \setminus \partial(G, \mathcal{P}) \). Then, for each \( i \), there is a \( j > i \) such that, if an element \([\varphi] \in H_c^k(U_j)\) is sent to 0 under \( H_c^k(U_j) \to H_c^k(\mathcal{X}) \), then it is sent to 0 under \( H_c^k(U_j) \to H_c^k(U_i) \).

**Proof.** Identify \( H_c^k(U_j) \) with the cohomology of the kernel of \( C_c^* (\mathcal{X}) \to C_c^* (\mathcal{X} \setminus U_i) \) and apply Proposition 4.18. \( \square \)

The following completes the proof of Theorem 1.3.

**Theorem 4.20.** If \((G, \mathcal{P})\) is a type \( F \) relatively hyperbolic \( PD(n) \) pair, then \( \partial(G, \mathcal{P}) \) is a homology \((n-1)\)-manifold.

**Proof.** Once we have the regularity of the compactly supported cochains, the proof follows exactly as Bestvina’s proof that the boundary of a hyperbolic \( PD(n) \) group is a homology \((n-1)\)-sphere (see [Bes96, 2.8]). For completeness we give the argument, filling in a few details.

To align notation with Bestvina’s, write \( Z = \partial(G, \mathcal{P}) \), \( X = \mathcal{X} \), and \( \bar{X} = \overline{X} = X \cup Z \). In this proof, \( H_k(\cdot) \) will denote Steenrod homology and \( H_c^{LF}(\cdot) \) will denote locally finite homology. For an exposition of these homology theories see [Per95].

We aim to show that, for any point \( z \in Z \),

\[ H_k(Z, Z \setminus \{z\}) \cong \begin{cases} 
\mathbb{Z} & k = n - 1 \\
0 & \text{otherwise}
\end{cases} \]

We have shown (Theorem 3.12) that \( Z \) is a \( Z \)-set in \( \bar{X} \), which is an absolute retract. In this setting, we have the following two facts, special cases of [Bes96, Proposition 1.8 and Remark 1.9]:

- If \( \{U_i\}_{i \in \mathbb{N}} \) is a neighborhood basis in \( \bar{X} \) of \( z \in Z \), then

\[ H_k(Z, Z \setminus \{z\}) = \lim_{k \to +1} H_c^{LF}(U_i). \]

- (Universal coefficients.) For each \( U_i \) there is a short exact sequence

\[ 0 \to \text{Ext}(H_c^{k+2}(U_i); \mathbb{Z}) \to H_c^{LF}(U_i) \to \text{Hom}(H_c^{k+1}(U_i); \mathbb{Z}) \to 0. \]
Since a direct limit of exact sequences is exact, we can use a direct limit of the short exact sequences $\mathcal{E}$ to compute $H_k(Z, Z \setminus \{z\})$. But the limits $\lim \text{Hom}(\{z\}, \mathbb{Z})$ and $\lim \text{Ext}(\{z\}, \mathbb{Z})$ depend only on the inverse system up to pro-isomorphism (see Chapter 11). Indeed, if $F$ is a contravariant functor, it sends pro-isomorphic systems to ind-isomorphic systems and colimits of ind-isomorphic systems are isomorphic. It is therefore enough to prove that the inverse system \( \{H^n(U_i)\}_{i \in \mathbb{N}} \) is pro-trivial when $k \neq n$, and pro-isomorphic to \( \{\mathbb{Z}\} \) when $k = n$. In other words, we want to show the inverse system \( \{H^n_c(U_i)\}_{i \in \mathbb{N}} \) is pro-isomorphic to the inverse system consisting of a single group, \( \{H^n_b(X)\} \).

To show that the two systems are pro-isomorphic, we give maps $p_i : H^n_b(X) \to H^n_c(U_i)$ and $q : H^n_c(U_0) \to H^n_b(X)$. When $H^n_b(X)$ is trivial, then these are zero. In general we take $q$ to be the map induced by the inclusion $U_0 \subseteq X$. Let $\alpha : \mathbb{N} \to \mathbb{N}$ be the assignment $i \mapsto j$ of Lemma 4.19. For $k = n$, we have $H^n_b(X) \cong \mathbb{Z}$. A cochain representing the generator can be translated into each $U_i$ by the action of $G$. Thus, the restriction $H^n_b(X) \to H^n_b(X\setminus U_i)$ is zero and, using the long exact sequence from Theorem A.8 $H^n_b(U_i) \to H^n_b(X)$ is surjective. Since $H^n_b(X)$ is free, this surjection admits a section, which we will denote $s_i$. Let $p_i$ be the composite $H^n_b(X) \xrightarrow{s_{\alpha(i)}} H^n_b(U_{\alpha(i)}) \to H^n_b(U_i)$.

We must check that the $p_i$ commute with the maps in the system \( \{H^n_c(U_i)\} \). Consider the following triangle.

$$
\begin{array}{ccc}
H^n_b(X) & \xrightarrow{p_i} & H^n_b(U_i) \\
\downarrow & & \downarrow \\
H^n_c(U_j) & \xrightarrow{\iota_*} & H^n_c(U_i)
\end{array}
$$

Let $\varphi$ represent a generator of $H^n_b(X)$. Then, $\iota_* \circ p_j[\varphi] - p_i[\varphi]$ is represented by a cochain supported in $U_{\alpha(i)}$. Moreover, this cochain is a coboundary in $X$ so, by definition of $\alpha$, $\iota_* \circ p_j[\varphi] - p_i[\varphi] = 0$.

That these maps give a pro-isomorphism can be checked using Lemma 4.19. For $k = n$, $p_j \circ \iota_* \circ p_j[\varphi] - q_i[\varphi] = 0$.

To conclude, $Z$ is $(n-1)$-dimensional (Corollary 4.9) and has the local homology of an $(n-1)$-manifold at every point, so it is a homology $(n-1)$-manifold. \hfill \Box

5. Topological dimension of the boundary.

In [BM91] it is established that for a hyperbolic group $G$, the topological dimension of $\partial G$ is exactly one less than $\max\{n \mid H^n(G; \mathbb{Z}) \neq 0\}$. We extend this to the relative setting in a special case:

**Theorem 5.1.** Let $(G, \mathcal{P})$ be type $F$ and relatively hyperbolic. Suppose further that $\text{cd}(G) < \text{cd}(G, \mathcal{P})$. Then

$$
\dim(\partial(G, \mathcal{P})) = \text{cd}(G, \mathcal{P}) - 1
$$

**Remark.** Under the hypotheses of Theorem 5.1 it must be the case that

$$
\text{cd}(G) = \max_{P \in \mathcal{P}} \text{cd}(P) = \text{cd}(G, \mathcal{P}) - 1.
$$

Moreover, if $\text{cd}(G) > 2$, we may apply the Eilenberg-Ganea Theorem as in the previous section to obtain Theorem 5.1. The proof we give in this section follows [BM91] and applies also to the case $\text{cd}(G) = 2$.

As in the previous section, we suppress integer coefficients. In the proof of [BM91, Corollary 1.4], Bestvina and Mess prove the following:

**Lemma 5.2.** Suppose $Z$ is a $Z$-set in $\hat{X}$ such that $X = \hat{X} \setminus Z$ is a locally finite CW complex of dimension $N$. Let $n - 1 = \max\{k \geq 0 \mid H^n(Z) \neq 0\}$ and let $C^k_c(X)$ denote the cellular $k$-cochains with compact support. If the cochain complex

$$
C^n_c(X) \to \cdots \to C^1_c(X) \to 0
$$

is regular, then $\dim(Z) = n - 1$. 
Proof of Theorem 5.1. Let \( n = \text{cd}(G, \mathcal{P}) \) and let \( N = \dim(\mathcal{X}) \). Note that \( \text{cd}(P) < n \) for all \( P \in \mathcal{P} \). Let \( C^k_c(\mathcal{X}) \) denote the cellular cochains of \( \mathcal{X} \) with compact support. Each horoball of \( \mathcal{X} \) is a product of a cell of \( \mathcal{P} \) ported cochains \( \mathcal{P} \) is regular.

We verify the hypotheses of Lemma 5.2, showing that the truncated complex of compactly supported cochains

\[
C^n_c(\mathcal{X}) \to \cdots \to C^N_c(\mathcal{X}) \to 0
\]

is regular.

We must show, for each \( k > n \), there is an \( M > 0 \) such that, if \( \varphi \in C^k_c(\mathcal{X}) \) is a coboundary, then it is the coboundary of some \( \psi \in C^{k-1}_c(\mathcal{X}) \) supported in a cellular \( M \)-neighborhood of \( \varphi \).

Let \( X = \mathcal{X}_1 \) and let \( Y = \mathcal{X}_1 \). The compactly supported \( k \)-cochains of \( \mathcal{X} \) admit the following decomposition

\[
C^k_c(\mathcal{X}) \cong C^k_c(\mathcal{X}) \oplus \left( \bigoplus_{m \in \mathbb{N}} C^k_c(Y) \right) \oplus \left( \bigoplus_{m \in \mathbb{N}} C^{k-1}_c(Y) \right).
\]

Letting \( e \) be a cell in either \( X \) or \( Y \) and \( e^* \) the cochain that sends \( e \) to 1, \( \delta : C^k_c(\mathcal{X}) \to C^{k-1}_c(\mathcal{X}) \) is defined by

\[
\delta(e^*,0,0) = \begin{cases} 
(\delta e^*,0,-e^*_n) & e \in Y \\
(\delta e^*,0,0) & e \notin Y
\end{cases}
\]

\[
\delta(0,e^*_m,0) = (0,(\delta e^*)_m,e^*_m - e^*_{m+1})
\]

\[
\delta(0,0,e^*_m) = (0,0,-\delta e^*_m)
\]

where \( e^*_m \) denotes the cocycle \( e^* \) in the \( m \)-th summand of \( \bigoplus_{m \in \mathbb{N}} C^k_c(Y) \). By our assumption that \( \text{cd}(G) < n \) and \( \text{cd}(P) < n \) for all \( P \in \mathcal{P} \), there are acyclic free \( \mathbb{Z}G \)-complexes (free resolutions of 0)

\[
\ldots \to F_{N-n+3} \to F_{N-n+2} \to C^{n-1}_c(X) \to C^n_c(X) \to \cdots \to C^n_c(Y) \to 0
\]

\[
\cdots \to F'_{N-n+3} \to F'_{N-n+2} \to C^{n-1}_c(Y) \to C^n_c(Y) \to \cdots \to C^n_c(Y) \to 0
\]

For these resolutions, there are chain homotopies \( h_X \) and \( h_Y \) between the identity and 0 (i.e. \( h\delta + \delta h = \text{Id} \)). Since each \( C^k_c(X) \) and \( C^k_c(Y) \) appearing in these resolutions is finitely generated, there is an \( M \) so that \( h_X \) and \( h_Y \) have displacement bounded by \( M \).

For \( k > n \), define \( : C^k_c(\mathcal{X}) \to C^{k-1}_c(\mathcal{X}) \) by \( H(\varphi,\varphi',\varphi'') = (h_X \varphi, h_Y \varphi', -h_Y \varphi'') \). A calculation shows that \( H\delta + \delta H = \text{Id} \). Now, if \( \varphi \) is a cocycle in \( C^k_c(\mathcal{X}) \) and \( k > n \), then \( \delta H \varphi = \varphi \). The claim follows from the fact that \( d_H(\text{supp}(H\varphi),\text{supp}(\varphi)) < N \).

With this claim, the result follows from Lemma 5.2 \( \square \)

Under the assumptions of Theorem 5.1, the group \( G \) is type \( F \) and thus \( \text{cd}(G, \mathcal{P}) \) is equal to \( \max\{n \mid H^n(G, \mathcal{P}; \mathbb{Z}G) \neq 0\} \) (see Proposition 2.21).

Conjecture 5.3. Let \((G, \mathcal{P})\) be relatively hyperbolic and type \( F \). Then

\[
\dim(\delta(G, \mathcal{P})) = \max\{n \mid H^n(G, \mathcal{P}; \mathbb{Z}G) \neq 0\} - 1.
\]

We are not sure if the equality should hold without the type \( F \) assumption.

Appendix A. Cohomology with compact support

The purpose of this appendix is to establish the long exact sequence for cohomology with compact support. This long exact sequence is well documented in texts on sheaf cohomology but we will need singular and simplicial statements to apply this to group cohomology. Moreover, the definition of singular cohomology with compact support in [Spa89] and [Hat02] differ slightly; the definition in [Spa89] is more compatible with sheaf cohomology while the definition in [Hat02] is more compatible...
with simplicial and cellular homology. One of our goals is to show that the definition in \cite{Hat02} is well behaved with respect to sheaf cohomology. The main result of this section is Theorem \ref{thm:main}. Fix an abelian group. In this section, we take coefficients in this abelian group or in the constant sheaf determined by this group.

**Definition A.1.** Suppose $X$ is a locally finite simplicial complex (or more generally, a locally finite $\Delta$-complex). Then we define the *simplicial $i$-cochains with compact support* to be the cochains $\varphi$ such that $\varphi(\sigma) = 0$ for all but finitely many $i$-simplices $\sigma$. We denote these cochains by $\Delta C^i_c(X)$. This gives a cochain complex and we define the *simplicial cohomology with compact support* $\Delta H^i_c(X)$ to be the cohomology of this complex.

**Definition A.2.** If $X$ is a locally compact space, we define the *singular $i$-cochains with compact support* to be the cochains $\varphi$ such that there is a compact subset $K \subseteq X$ such that $\varphi(\sigma) = 0$ for all singular simplices $\sigma$ with image in $X \setminus K$. We will denote these as $\sigma C^i_c(X)$. This gives a cochain complex and we define the *singular cohomology with compact support* $\sigma H^i_c(X)$ to be the cohomology of this complex.

**Remark.** In the case that $X$ is a locally finite simplicial complex, singular cohomology with compact support and simplicial cohomology with compact support agree. Moreover, the isomorphism is induced by a map of cochain complexes. Similarly, if $X$ is a locally finite CW-complex, singular cohomology with compact support and cellular cohomology with compact support agree. However, this isomorphism is not induced by a chain map.

In order to relate singular cohomology with compact support to sheaf cohomology with compact support, we need to make the following definitions (see \cite[I.7]{Bre97}).

**Definition A.3.** Let $S^i_c(X)$ denote the singular $i$-cochains $\varphi$ such that there exists a compact subset $K \subseteq X$ where, for each $x \in X \setminus K$, there is a open neighborhood $W$ of $x$ such that $\varphi \mapsto 0$ under $C^i(W) \to C^i(X)$. Let $S^0_c(X)$ denote the singular $0$-cochains $\varphi$ such that, for each $x \in X$, there is an open neighborhood $W$ of $x$ such that $\varphi \mapsto 0$ under $C^0(W) \to C^0(X)$.

The cochains $S^i_c(X)$ (resp. $S^0_c(X)$) are the global sections with compact (resp. trivial) support of the singular cochain presheaf. It follows from definitions that there is an inclusion $\sigma C^i_c(X) \to S^i_c(X)$.

**Definition A.4.** Let $\sigma = \sum_{j=1}^n a_j \sigma_j \in \sigma C^i_c(X)$ be a singular chain where $\sigma_j : \Delta^i \to X$ and $\sigma_j \neq \sigma_{j'}$ when $j \neq j'$. Then the *support of $\sigma$* is the union of the images of the $\sigma_j$. We will denote this by $\supp(\sigma)$.

We first record a result in Spanier.

**Lemma A.5.** Let $U$ be an open cover of $X$. Let $\sigma C_i(U)$ denote the $U$-small singular $i$-chains (i.e. those supported in some $U \in U$). Then the inclusion $\iota : \sigma C_i(U) \to \sigma C^i_c(X)$ is a chain homotopy equivalence. Moreover, the inverse $g : \sigma C^i_c(X) \to \sigma C_i(U)$ and homotopy $h : \sigma C^i_c(X) \to \sigma C_{i+1}(X)$ can be taken such that, for $\sigma \in \sigma C^i_c(X)$, $\supp g(\sigma) \subseteq \supp \sigma$ and $\supp h(\sigma) \subseteq \supp \sigma$.

The first part of this statement is \cite[Theorem IV.4.14]{Spa89}. The second part comes from the construction given in the proof.

**Proposition A.6.** The complex $S^*_c(X)$ is acyclic.

**Proposition A.7.** Suppose $X$ is locally compact. Then, the inclusion $\sigma C^i_c(X) \to S^i_c(X)$ induces an isomorphism on cohomology groups.

**Proof.** Let $D^i$ denote the cokernel of $\sigma C^i_c(X) \to S^i_c(X)$. If the cochain complex $D^i$ is acyclic, then the proposition follows. Note that the submodule $S^i_0(X)$ surjects to $D^i$ under the map $S^i_c(X) \to D^i$. Let $E^i$ be the kernel of the map $S^i_0(X) \to D^i$. Since $S^i_0(X)$ is acyclic, it suffices to show that $E^i$ is acyclic. $E^i$ consists of the cochains $\varphi \in S^i_0(X)$ such that there is a compact subset $K \subseteq X$ with $\varphi(\sigma) = 0$ for all $\sigma$ whose image is in $X \setminus K$. 

Suppose \( \varphi \in E^i \) is a cocycle. Then, we may consider \( \varphi \) as a cocycle in \( S^0_c(X) \). There is a compact set \( K \) such that \( \varphi(\sigma) = 0 \) whenever \( \text{supp}(\sigma) \subseteq X \setminus K \). There is also an open cover \( U \) of \( X \) such that \( \varphi(\sigma) = 0 \) for all \( \sigma \in C_i,\sigma(U) \). Let \( \iota, g \) and \( h \) be as in Proposition A.5 and let \( \iota^*, g^* \) and \( h^* \) denote their duals on cochains. Then, \( h\partial + \partial h = 1 - \iota \circ g \) so \( \partial h^* + h^*\delta = 1 - g^* \circ \iota^* \). Since \( \varphi \) is a cocycle and \( \iota^*(\varphi) = 0 \), we obtain \( \partial h^* \varphi = \varphi \). We claim that \( h^* \varphi \in E^{i-1} \). Indeed, if \( \sigma \) is a singular \((i-1)\)-simplex with \( \text{supp}(\sigma) \subseteq X \setminus K \), then \( \text{supp}(h(\sigma)) \subseteq X \setminus K \). Therefore, \( \varphi(h(\sigma)) = (h^*\varphi)(\sigma) = 0 \). This implies that \( E^i \) is acyclic.

We can now prove the following theorem.

**Theorem A.8.** Suppose \( X \) is locally compact, locally contractible and Hausdorff. Let \( F \subseteq X \) be a closed, locally contractible subset such that \( U := X \setminus F \) is also locally contractible. Then, there is the following long exact sequence.

\[
\cdots \to \sigma H^i_c(U) \to \sigma H^i_c(X) \to \sigma H^i_c(F) \to \sigma H^{i+1}_c(U) \to \cdots
\]

Moreover, if \( X \) is a simplicial complex and \( F \) is a subcomplex, then there is the following long exact sequence.

\[
\cdots \to \sigma H^i_c(U) \to \Delta H^i_c(X) \to \Delta H^i_c(F) \to \sigma H^{i+1}_c(U) \to \cdots
\]

**Proof.** For a closed subspace \( F \), there is a surjection \( \sigma C^i_c(X) \to \sigma C^i_c(F) \). Let \( \sigma C^i_c(X,F) \) denote the kernel of this map. Similarly, there is a surjection \( S^i_c(X) \to S^i_c(F) \) and we let \( S^i_c(X,F) \) denote the kernel. This gives the following commuting diagram with exact rows.

\[
\begin{array}{cccc}
0 & \to & \sigma C^i_c(X,F) & \to & \sigma C^i_c(X) & \to & \sigma C^i_c(F) & \to & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & S^i_c(X,F) & \to & S^i_c(X) & \to & S^i_c(F) & \to & 0 \\
\end{array}
\]  
(6)

The middle and right vertical maps in (6) are the inclusions of cochains and the left vertical map exists by exactness. By Proposition A.7 the middle and right vertical maps induce isomorphisms on cohomology. Thus, \( \sigma C^i_c(X,F) \to S^i_c(X,F) \) induces an isomorphism on cohomology.

Since \( X \) and \( F \) are locally contractible and locally compact, the bottom row of Diagram 6 computes sheaf cohomology (see [Bre97, III.1]). So, the cohomology of the complex \( \sigma C^i_c(X,F) \) is isomorphic to the relative sheaf cohomology with compact support of the pair \((X,F)\) with coefficients in the constant sheaf. By [Bre97, Proposition II.12.3], this is isomorphic to \( H^i_c(U) \). Since \( U \) is locally contractible, this is isomorphic to singular cohomology with compact support. \( \square \)

We will need the following consequence of the proof of Theorem A.8.

**Theorem A.9.** Let \( X, F \) and \( U \) be as in Theorem A.8. Then the \( i \)-th cohomology of \( \sigma C^i_c(X,F) \) is \( \sigma H^i_c(U) \). If \( X \) is a simplicial complex and \( F \) is a subcomplex then the \( i \)-th cohomology of \( \Delta C^i_c(X,F) \) is \( \sigma H^i_c(U) \).

We will also need the following corollary of Theorem A.8.

**Corollary A.10.** Suppose \( X \) is locally compact, locally contractible and Hausdorff. Then, \( \sigma H^*_c([0,1] \times X) = 0 \).

**Proof.** The inclusion \( \{1\} \times X \to [0,1] \times X \) is a proper homotopy equivalence so it induces isomorphisms on cohomology with compact support. The result follows from the long exact sequence of Theorem A.8. \( \square \)
