Abstract
In this article, various aspects of Laplacian spectra of power graphs of finite cyclic, dicyclic and finite $p$-groups are considered. The algebraic connectivity is studied and the multiplicity of the Laplacian spectral radius is determined completely for power graphs of all of these groups. Then the equality of the vertex connectivity and the algebraic connectivity is characterized for power graphs of all of the above groups. Orders of dicyclic groups, for which their power graphs are Laplacian integral, are determined. Moreover, it is proved that the notion of equality of the vertex connectivity and the algebraic connectivity and the notion of Laplacian integral are equivalent for power graphs of dicyclic groups. All possible values of Laplacian eigenvalues are obtained for power graphs of finite $p$-groups. This shows that power graphs of finite $p$-groups are Laplacian integral.

1 Introduction

In literature, there are various graphs constructed from groups and semigroups, e.g., Cayley graphs (cf. [5]), intersection graphs (cf. [30]), commuting graphs (cf. [1]) and prime graphs (cf. [29]). The notion of directed power graph of a semigroup $S$ was introduced by Kelarev and Quinn [18] as the directed graph with vertex set $S$ and there is an arc from a vertex $u$ to another vertex $v$ if $v = u^\alpha$ for some $\alpha \in \mathbb{N}$. Followed by this, Chakrabarty et al. [6] defined the power graph $\mathcal{P}(S)$ of a semigroup $S$ as the (undirected) graph with vertex set $S$ and distinct vertices $u$ and $v$ are adjacent if $v = u^\alpha$ for some $\alpha \in \mathbb{N}$ or $u = v^\beta$ for some $\beta \in \mathbb{N}$.
In recent years, researchers have studied various properties of power graphs and have shown their usefulness in characterizing finite groups. Cameron and Ghosh [4] proved that two finite abelian groups with isomorphic power graphs are isomorphic. Cameron [3] proved that if two finite groups have isomorphic power graphs, then they have the same numbers of elements of each order. Curtin and Pourgholi [12] showed that among all finite groups of a given order, the cyclic group of that order has the maximum number of edges in its power graph. In [11,25], upper bounds of the vertex connectivity along with some cases of equality were found for power graphs of finite cyclic groups. The proper power graph of a group is obtained by deleting the identity element from its power graph. In [2,14], the components of proper power graphs of some finite groups were studied. In [20], rainbow connection number of power graphs of finite groups were studied. For more interesting results on power graphs, the reader may refer to [22,23,26,28].

All graphs considered hereafter are undirected, finite and simple (i.e., no loops or parallel edges).

For any graph $\Gamma$ with ordered vertex set $\{v_1, v_2, \ldots, v_n\}$, the Laplacian matrix $L(\Gamma)$ of $\Gamma$ is defined as $L(\Gamma) = D(\Gamma) - A(\Gamma)$, where $D(\Gamma)$ is the diagonal matrix whose $(i, i)$th entry is the degree of $v_i$ and $A(\Gamma)$ is the adjacency matrix of $\Gamma$ whose $(i, j)$th entry is 1 if $v_i$ is adjacent to $v_j$ and 0 otherwise. The matrix $L(\Gamma)$ is symmetric and positive semidefinite, so that its eigenvalues are real and non-negative (cf. [24]). Furthermore, the sum of each row (column) of $L(\Gamma)$ is zero, so that it is singular and consequently, its smallest eigenvalue is 0. The eigenvalues of $L(\Gamma)$ are called the Laplacian eigenvalues of $\Gamma$ and are denoted by $\lambda_1(\Gamma) \geq \lambda_2(\Gamma) \geq \cdots \geq \lambda_n(\Gamma) = 0$ arranged in non-increasing order. Now let $\lambda_{n_1}(\Gamma) > \lambda_{n_2}(\Gamma) > \cdots > \lambda_{n_r}(\Gamma) = 0$ be the distinct Laplacian eigenvalues of $\Gamma$ with multiplicities $m_1, m_2, \ldots, m_r$, respectively. Then the Laplacian spectrum of $\Gamma$, that is, the spectrum of $L(\Gamma)$, is represented as $\left(\begin{array}{c}
\lambda_{n_1}(\Gamma) \\
\lambda_{n_2}(\Gamma) \\
\vdots \\
\lambda_{n_r}(\Gamma) \\
m_1 \\
m_2 \\
\cdots \\
m_r
\end{array}\right)$. Fiedler [15] termed $\lambda_{n-1}(\Gamma)$ as the algebraic connectivity of $\Gamma$, viewing it as a measure of connectivity of $\Gamma$. It is known that $\lambda_{n-1}(\Gamma) > 0$ if and only if $\Gamma$ is connected. The largest Laplacian eigenvalue $\lambda_1(\Gamma)$ is called the Laplacian spectral radius of $\Gamma$. A graph is Laplacian integral if all its Laplacian eigenvalues are integers. More results on Laplacian spectra of graphs can be found in the text [13].

Recently, researchers have studied various spectral properties of power graphs of finite groups. Chattopadhyay and Panigrahi [9] investigated Laplacian spectra of power graphs of the finite cyclic group $\mathbb{Z}_n$ and the dihedral group $D_n$ (of order $2n$). They showed that the Laplacian spectral radius of the power graph of any finite group $G$ is the order of $G$. Moreover, they expressed the Laplacian characteristic polynomial of $\mathcal{G}_r(D_n)$ in terms of that of $\mathcal{G}_r(\mathbb{Z}_n)$. In [7], the Laplacian spectrum of power graph of the dicyclic group $Q_n$ (of order $4n$), when $n$ is a power of 2, was computed. In [16], Hamzeh and Ashrafi investigated adjacency and Laplacian spectra of power graphs of $\mathbb{Z}_n$, $D_n$, $Q_n$ and $SD_n$ (semi-dihedral group of order $8n$). Further, in [10,21], adjacency spectra of power graphs of certain finite groups were studied. Kirkland et al. [19] supplied an equivalent condition for the equality of vertex connectivity and algebraic connectivity of non-complete and connected graphs in terms of graph join operation.
In this article, we study Laplacian spectra of power graphs of \( \mathbb{Z}_n \), \( Q_n \) and finite \( p \)-groups. For \( \mathcal{G}(\mathbb{Z}_n) \), we find all \( n \) for which its algebraic connectivity is \( \phi(n) + 1 \) and then determine the multiplicity of its Laplacian spectral radius completely. We provide bounds for the algebraic connectivity of \( \mathcal{G}(Q_n) \) and find all \( n \) for which it is equal to 2. Moreover, we obtain the multiplicity of the Laplacian spectral radius of \( \mathcal{G}(Q_n) \) for all \( n \). For a finite \( p \)-group \( G \), we show that the statements: (i) the algebraic connectivity of \( \mathcal{G}(G) \) is 1, (ii) the multiplicity of the Laplacian spectral radius of \( \mathcal{G}(G) \) is one, and (iii) \( G \) is neither cyclic nor generalized quaternion, are all equivalent. This, when taken together with known results, determines the algebraic connectivity and the multiplicity of the Laplacian spectral radius of \( \mathcal{G}(G) \) completely.

We characterize the equality of the vertex connectivity and the algebraic connectivity for power graphs of \( \mathbb{Z}_n \), \( Q_n \) and finite \( p \)-groups. Furthermore, we determine all \( n \) such that \( \mathcal{G}(Q_n) \) is Laplacian integral. In fact, we prove that the statements: (i) the vertex connectivity and the algebraic connectivity of \( \mathcal{G}(Q_n) \) are equal, (ii) the algebraic connectivity of \( \mathcal{G}(Q_n) \) is an integer, (iii) \( \mathcal{G}(Q_n) \) is Laplacian integral, and (iv) \( Q_n \) is generalized quaternion, are all equivalent. When \( G \) is a finite \( p \)-group, we provide iterative methods to find the structure and the Laplacian characteristic polynomial of \( \mathcal{G}(G) \). Then we determine all possible values of Laplacian eigenvalues of \( \mathcal{G}(G) \), and conclude that power graphs of finite \( p \)-groups are always Laplacian integral.

2 Preliminaries

In this section, we state the relevant definitions and recall the necessary results from literature. Additionally, we also fix some notations.

For any graph \( \Gamma \), its set of vertices and set of edges are denoted by \( V(\Gamma) \) and \( E(\Gamma) \), respectively. A graph with just one vertex (hence no edges) is called a trivial graph. The complement \( \overline{\Gamma} \) of \( \Gamma \) is the graph with vertex set \( V(\Gamma) \) and two (distinct) vertices are adjacent if they are non-adjacent in \( \Gamma \). The vertex connectivity \( \kappa(\Gamma) \) of \( \Gamma \) is the minimum number of vertices whose removal makes \( \Gamma \) disconnected or a trivial graph. By convention, vertex connectivity of disconnected graphs or the trivial graph are taken to be 0. Up to isomorphism, the complete graph on \( n \) vertices is denoted by \( K_n \).

In this article, \( e \) always denotes the identity element of a (multiplicative) group. Let \( G \) be a group and \( g \in G \). The order of \( g \) in \( G \) is denoted by \( o(g) \) and the cyclic subgroup generated by \( g \) is denoted by \( \langle g \rangle \). Let \( \approx \) denote the equivalence relation on \( G \) defined by \( g \approx h \) if \( \langle g \rangle = \langle h \rangle \). An equivalence class under \( \approx \) is referred to as a \( \approx \)-class and the \( \approx \)-class of any \( g \in G \) is denoted by \( [g] \).

In [6], Chakrabarty et al. proved that for any group \( G \), \( \mathcal{G}(G) \) is connected if and only if all elements of \( G \) have finite order. Moreover, they determined all finite groups whose power graphs are complete.

**Theorem 1** [6, Theorem 2.12] Let \( G \) be a finite group. Then \( \mathcal{G}(G) \) is complete if and only if \( G \) is a cyclic group of order one or \( p^\alpha \) for some prime \( p \) and \( \alpha \in \mathbb{N} \).
For $n \in \mathbb{N}$, the additive group of integers modulo $n$ is denoted by $\mathbb{Z}_n = \{0, 1, \ldots, n - 1\}$. We denote the set consisting of the identity element and the generators of $\mathbb{Z}_n$ by $\mathbb{Z}_n\!'$, i.e., $\mathbb{Z}_n\!' = \{0\} \cup \{a \in \mathbb{Z}_n : 1 \leq a < n, \gcd(a, n) = 1\}$. Further, we denote $\mathbb{Z}_n' = \mathbb{Z}_n - \mathbb{Z}_n\!'$ and $\mathcal{G}(\mathbb{Z}_n) = \mathcal{G}(\mathbb{Z}_n) - \mathbb{Z}_n\!'$. Notice that each vertex in $\mathbb{Z}_n\!'$ is adjacent to every other vertex of $\mathcal{G}(\mathbb{Z}_n)$.

We require the following results on power graphs in Sect. 3.

**Lemma 1** [25, Proposition 2.5] Let $n \geq 2$ be a composite number. Then $\mathcal{G}'(\mathbb{Z}_n)$ is disconnected if and only if $n$ is a product of two distinct primes.

**Lemma 2** [8, Theorem 7] For any integer $n \geq 2$, $\kappa(\mathcal{G}(Q_n)) = 2$.

**Lemma 3** [23, Corollary 4.2] For any finite $p$-group $G$, $\mathcal{G}^*(G)$ is connected if and only if $G$ is either cyclic or generalized quaternion.

The isomorphism of graphs and groups is denoted by $\cong$. For $n \in \mathbb{N}$, the number of positive integers that do not exceed $n$ and are relatively prime to $n$ is denoted by $\phi(n)$, and the function $\phi$ is known as Euler’s phi function. We say that $n$ is a prime power $\sqrt[n]{n}$ for some prime $p$ and $\alpha \in \mathbb{N}$.

For any graph $\Gamma$, the characteristic polynomial $\det(xI - L(\Gamma))$ of $L(\Gamma)$ is called the Laplacian characteristic polynomial of $\Gamma$ and is denoted by $\Theta(\Gamma, x)$. If $\Gamma$ is a null graph, for both convenience and consistency, we write $\Theta(\Gamma, x) = 1$.

Now we recall some necessary results on Laplacian spectra of graphs.

**Theorem 2** [13, Theorem 7.1.2] For any graph $\Gamma$, the multiplicity of 0 as an eigenvalue of $L(\Gamma)$ is equal to the number of components of $\Gamma$.

A particular case of Theorem 2 is the following result due to Fiedler.

**Theorem 3** [15] A graph $\Gamma$ is connected if and only if $\lambda_{n-1}(\Gamma) > 0$.

**Theorem 4** [24, Theorem 3.6] For any graph $\Gamma$ on $n$ vertices, $\lambda_n(\overline{\Gamma}) = 0$, and $\lambda_k(\overline{\Gamma}) = n - \lambda_{n-k}(\Gamma)$ for $1 \leq k \leq n - 1$.

**Theorem 5** [15] For any graph $\Gamma$, $\lambda_1(\Gamma) = \max_{1 \leq i \leq r} \lambda_1(\Gamma_i)$, where $\Gamma_1, \ldots, \Gamma_r$ are the components of $\Gamma$.

**Theorem 6** [24, Theorem 2.2] If $\Gamma$ is a graph with $n$ vertices, then $\lambda_1(\Gamma) \leq n$. Equality holds if and only if $\overline{\Gamma}$ is not connected.

The union of graphs $\Gamma_1$ and $\Gamma_2$, denoted by $\Gamma_1 \cup \Gamma_2$, is the graph with vertex set $V(\Gamma_1) \cup V(\Gamma_2)$ and edge set $E(\Gamma_1) \cup E(\Gamma_2)$. Evidently, union of graphs is associative, so that union of any finite number of graphs can be defined accordingly. If $\Gamma_1$ and $\Gamma_2$ are disjoint, i.e., they have no common vertices, we refer to their union as a disjoint union, and denote it by $\Gamma_1 + \Gamma_2$. For pairwise disjoint graphs $\Gamma_1, \Gamma_2, \ldots, \Gamma_r$, we denote their union by $\sum_{i=1}^r \Gamma_i$. If $\Gamma_1$ and $\Gamma_2$ are disjoint, their join $\Gamma_1 \vee \Gamma_2$ is the graph obtained by taking $\Gamma_1 + \Gamma_2$ and adding all edges $\{u, v\}$ with $u \in V(\Gamma_1)$ and $v \in V(\Gamma_2)$. For any graph $\Gamma$, up to isomorphism, $r\Gamma$ denotes the graph obtained by taking disjoint union of $r$ copies of $\Gamma$.
Theorem 7 [24] If $\Gamma$ is the disjoint union of graphs $\Gamma_1, \Gamma_2, \ldots, \Gamma_r$, then

$$\Theta(\Gamma, x) = \prod_{i=1}^{r} \Theta(\Gamma_i, x).$$

Theorem 8 [24] If $\Gamma_1$ and $\Gamma_2$ are disjoint graphs on $n_1$ and $n_2$ vertices, respectively, then

$$\Theta(\Gamma_1 \vee \Gamma_2, x) = \frac{x(x - n_1 - n_2)}{(x - n_1)(x - n_2)} \Theta(\Gamma_1, x - n_2) \Theta(\Gamma_2, x - n_1).$$

In the following results, the Laplacian spectrum was computed for power graphs of cyclic groups of prime power order and generalized quaternion groups.

Lemma 4 [9, Corollary 3.3] If $n$ is a prime power, then the Laplacian spectrum of $G(Z_n)$ is given by

$$\left(0 \ n \ n - 1\right).$$

Lemma 5 [7, Theorem 4.3.3] For any integer $\alpha \geq 2$, the Laplacian spectrum of $G(Q_{2^\alpha - 1})$ is given by

$$\begin{pmatrix} 0 & 2 & 4 & 2^\alpha & 2^{\alpha+1} \\ 1 & 2^{\alpha-1} & 2^\alpha - 1 & 2^\alpha - 3 & 2 \end{pmatrix}.$$ 

3 Main Results

We now present our results on Laplacian spectra of power graphs of finite cyclic, dicyclic and finite $p$-groups in Sects. 3.1, 3.2 and 3.3, respectively.

By applying Theorem 8 to $G \cong K_1 \vee \Gamma^*(G)$, we get

$$\Theta(G, x) = \frac{x(x - |G|)}{x - 1} \Theta(\Gamma^*(G), x - 1).$$

Thus, if $G$ is a group of order $n \geq 3$, then for any $2 \leq i \leq n - 1$,

$$\lambda_i(G) = \lambda_{i-1}(\Gamma^*(G)) + 1.$$ (1)

From (1) and Theorem 3, we have the following lemma.

Lemma 6 Let $G$ be a finite group of order $n \geq 3$. Then the algebraic connectivity of $G$ is 1 if and only if its vertex connectivity is 1.

3.1 Finite Cyclic Group

In this subsection, we study the algebraic connectivity of $G(Z_n)$ and find the multiplicity of its Laplacian spectral radius (which is $n$) completely. Then we characterize the equality of the vertex connectivity and the algebraic connectivity of $G(Z_n)$.
Observe that \( \Theta(G'(\mathbb{Z}_n), x - \phi(n) - 1) \) equals with the characteristic polynomial of the submatrix of \( L(G'(\mathbb{Z}_n)) \) obtained by deleting rows and columns corresponding to the elements of \( \mathbb{Z}_n \). Thus by [9, Theorem 2.2], we have the following useful lemma.

**Lemma 7** If the integer \( n > 1 \) is not a prime number, then

\[
\lambda_i(G(\mathbb{Z}_n)) = \begin{cases} 
  n & \text{for } 1 \leq i \leq \phi(n) + 1, \\
  \lambda_{i-\phi(n)-1}(G'(\mathbb{Z}_n)) + \phi(n) + 1 & \text{for } \phi(n) + 2 \leq i \leq n - 1, \\
  0 & \text{for } i = n.
\end{cases}
\]

It is known that the algebraic connectivity of \( G(\mathbb{Z}_n) \) is bounded below by \( \phi(n) + 1 \) (cf. [9]). We now determine all \( n \) for which the equality holds.

**Theorem 9** For an integer \( n > 1 \), the algebraic connectivity of \( G(\mathbb{Z}_n) \) is \( \phi(n) + 1 \) if and only if \( n \) is a prime number or product of two distinct primes.

**Proof** Let the algebraic connectivity of \( G(\mathbb{Z}_n) \) be \( \phi(n) + 1 \). Observe that \( \phi(n) + 1 = n \) if and only if \( n \) is a prime number. Now suppose that \( n \) is not prime. By Lemma 7, the algebraic connectivity of \( G'(\mathbb{Z}_n) \) is 0. Thus by Theorem 3, \( G'(\mathbb{Z}_n) \) is disconnected. Hence by applying Lemma 1, we conclude that \( n \) is a product of two distinct primes. Proof of the converse follows from [9, Theorem 2.12].

The following theorem obtains the multiplicity of \( n \) as a Laplacian eigenvalue of \( G(\mathbb{Z}_n) \) for all \( n \in \mathbb{N} \).

**Theorem 10** For an integer \( n > 1 \), the multiplicity of the Laplacian eigenvalue \( n \) of \( G(\mathbb{Z}_n) \) is

\[ n - 1 \] if \( n \) is a prime power,
\[ \phi(n) + 1 \] otherwise.

**Proof** If \( n \) is a prime power, then the multiplicity of the Laplacian eigenvalue \( n \) of \( G(\mathbb{Z}_n) \) is \( n - 1 \) (cf. Lemma 4). Now suppose \( n \) is not a prime power. Then from [9, Lemma 2.11], \( G'(\mathbb{Z}_n) \) is connected. Additionally, \( |\mathbb{Z}_n| = \phi(n) + 1 \). Thus by applying Theorem 6, we get \( \lambda_1(G'(\mathbb{Z}_n)) < n - \phi(n) - 1 \). This together with Lemma 7 yield \( \lambda_i(G(\mathbb{Z}_n)) < n \) for all \( \phi(n) + 2 \leq i \leq n \). Hence, by following Lemma 7 once again, the multiplicity of \( n \) as a Laplacian eigenvalue of \( G(\mathbb{Z}_n) \) is \( \phi(n) + 1 \).

We now determine all \( n \) for which the vertex connectivity and the algebraic connectivity of \( G(\mathbb{Z}_n) \) are equal.

**Theorem 11** For any integer \( n > 1 \), \( \kappa(G(\mathbb{Z}_n)) = \lambda_{n-1}(G(\mathbb{Z}_n)) \) if and only if \( n \) is a product of two distinct primes.

**Proof** Let \( n \) be a product of two distinct primes. Then from [8, Theorem 3(ii)] and [9, Corollary 2.6], both \( \kappa(G(\mathbb{Z}_n)) \) and \( \lambda_{n-1}(G(\mathbb{Z}_n)) \) equal \( \phi(n) + 1 \).

Now suppose \( n \) is not a product of two distinct primes. If \( n \) is a prime power, then considering Theorem 1, \( \kappa(G(\mathbb{Z}_n)) = n - 1 \) and \( \lambda_{n-1}(G(\mathbb{Z}_n)) = n \). That is, the equality \( \Box \) Springer
does not hold. Thus \( n \) has at least two distinct prime factors. We recall from [19] that for any graph \( \Gamma \) on \( n \) vertices, if both \( \Gamma \) and \( \overline{\Gamma} \) are connected, then \( \kappa(\Gamma) \neq \lambda_{n-1}(\Gamma) \). By Lemma 1, \( \mathcal{G}'(\mathbb{Z}_n) \) is connected and by [9, Lemma 2.11], \( \mathcal{G}'(\mathbb{Z}_n) \) is connected. Hence we have \( \kappa(\mathcal{G}'(\mathbb{Z}_n)) \neq \lambda_{n-\phi(n)-2}(\mathcal{G}'(\mathbb{Z}_n)) \). Additionally, it was ascertained in [25, Lemma 2.4] that \( \kappa(\mathcal{G}(\mathbb{Z}_n)) = \kappa(\mathcal{G}'(\mathbb{Z}_n)) + \phi(n) + 1 \). Consequently, using Lemma 7, we get \( \kappa(\mathcal{G}(\mathbb{Z}_n)) \neq \lambda_{n-1}(\mathcal{G}(\mathbb{Z}_n)) \).

\[ \square \]

### 3.2 Dicyclic Group

In this subsection, we give bounds of the algebraic connectivity and determine the multiplicity of the Laplacian spectral radius of \( \mathcal{G}(\mathbb{Q}_n) \). Then we prove that the vertex connectivity and the algebraic connectivity of \( \mathcal{G}(\mathbb{Q}_n) \) are equal if and only if \( \mathcal{G}(\mathbb{Q}_n) \) is Laplacian integral. Moreover, we show that the above are equivalent to each of the statements that the algebraic connectivity of \( \mathcal{G}(\mathbb{Q}_n) \) is 2 and \( \mathbb{Q}_n \) is generalized quaternion. We begin by formally stating the definition of a dicyclic group.

For an integer \( n \geq 2 \), the dicyclic group \( \mathbb{Q}_n \) is a finite group of order \( 4n \) having presentation

\[ \mathbb{Q}_n = \langle a, b \mid a^{2n} = e, a^n = b^2, ab = ba^{-1} \rangle, \tag{2} \]

where \( e \) is the identity element of \( \mathbb{Q}_n \). When \( n \) is a power of 2, \( \mathbb{Q}_n \) is called a generalized quaternion group of order \( 4n \). Throughout this subsection, we follow the above presentation of \( \mathbb{Q}_n \).

It is known that \( (a^i b)^2 = a^n \) for all \( 0 \leq i \leq 2n - 1 \), and

\[ \langle a^i b \rangle = \langle a^{n+i} b \rangle = \{e, a^i b, a^n, a^{n+i} b\} \text{ for all } 0 \leq i \leq n - 1. \tag{3} \]

**Lemma 8** [27] Any element of \( \mathbb{Q}_n - \langle a \rangle \) is of the form \( a^i b \) for some \( 0 \leq i \leq 2n - 1 \).

We find bounds of the algebraic connectivity of \( \mathcal{G}(\mathbb{Q}_n) \) in the following lemma.

**Lemma 9** For any integer \( n \geq 2 \), the algebraic connectivity of \( \mathcal{G}(\mathbb{Q}_n) \) satisfies

\[ 1 < \lambda_{4n-1}(\mathcal{G}(\mathbb{Q}_n)) \leq 2. \]

**Proof** Considering Lemma 2, \( \mathcal{G}^*(\mathbb{Q}_n) \) is connected. Thus it follows from Theorem 6 that \( \lambda_1(\mathcal{G}^*(\mathbb{Q}_n)) < 4n - 1 \). Moreover, by applying Theorem 5, we have

\[ \lambda_1(\mathcal{G}(\mathbb{Q}_n)) = \max\{\lambda_1(\mathcal{G}^*(\mathbb{Q}_n)), \lambda_1(\mathcal{G}(\{e\}))\} = \lambda_1(\mathcal{G}^*(\mathbb{Q}_n)). \]

Accordingly, \( \lambda_1(\mathcal{G}(\mathbb{Q}_n)) < 4n - 1 \). Hence by Theorem 4, \( \lambda_{4n-1}(\mathcal{G}(\mathbb{Q}_n)) > 1 \). In addition to this, by following the proof of [7, Theorem 4.33], 2 is a Laplacian eigenvalue of \( \mathcal{G}(\mathbb{Q}_n) \). We thus get the desired inequality. \( \square \)

The following result determines when exactly a dicyclic group is generalized quaternion in terms of its power graph.
Proposition 1 For any integer \( n \geq 2 \), \( a^n \) is adjacent to all other vertices of \( \mathcal{G}(Q_n) \) if and only if \( Q_n \) is generalized quaternion.

Proof Let \( Q_n \) be generalized quaternion. Then it follows from Theorem 1 that \( \langle a \rangle \cong \mathbb{Z}_{2n} \) is a clique in \( \mathcal{G}(Q_n) \). As a result, \( a^n \) is adjacent to all other elements of \( \langle a \rangle \) in \( \mathcal{G}(Q_n) \). Moreover, from (3), \( a^n \) is adjacent to \( a^i b \) for all \( 0 \leq i \leq 2n \). Finally, applying Lemma 8 we deduce that \( a^n \) is adjacent to all other vertices of \( \mathcal{G}(Q_n) \).

Whereas, if \( Q_n \) is not generalized quaternion, then there exists a prime factor \( p > 2 \) of \( n \). Then \( a^{2n/p} \) is an element of order \( p \). As the order of \( a^n \) is 2, orders of \( a^n \) and \( a^{2n/p} \) are thus relatively prime. Hence they are not adjacent in \( \mathcal{G}(Q_n) \). This concludes proof of the converse. \( \square \)

Now we obtain the multiplicity of the Laplacian spectral radius of \( \mathcal{G}(Q_n) \) for all \( n \).

Theorem 12 For any integer \( n \geq 2 \), the Laplacian eigenvalue \( 4n \) of \( \mathcal{G}(Q_n) \) has multiplicity two if \( Q_n \) is generalized quaternion and one otherwise.

Proof In view of (3) and Lemma 8, \( a^n \) is adjacent to every element of \( Q_n - \langle a \rangle \). Moreover, we observe that no element of \( Q_n - \langle a \rangle \) is adjacent to any element of \( \langle a \rangle - \{ e, a^n \} \) in \( \mathcal{G}(Q_n) \). Hence \( \mathcal{G}(Q_n) - \{ e, a^n \} \) is connected. This together with Proposition 1 imply that the number of components of \( \mathcal{G}(Q_n) \) is three if \( n \) is a power of 2 and two otherwise. Accordingly, by Theorem 2, the multiplicity of 0 as a Laplacian eigenvalue of \( \mathcal{G}(Q_n) \) is three if \( n \) is a power of 2 and two otherwise. Furthermore, by Theorem 4, the multiplicity of \( 4n \) as a Laplacian eigenvalue of \( \mathcal{G}(Q_n) \) is equal to one less than the multiplicity of 0 as a Laplacian eigenvalue of \( \mathcal{G}(Q_n) \). Hence the result follows. \( \square \)

We require the following result on the characterization of graphs with equal vertex and algebraic connectivity.

Lemma 10 [19, Theorem 2.1] Let \( \Gamma \) be a non-complete and connected graph on \( n \) vertices. Then \( \kappa(\Gamma) = \lambda_{n-1}(\Gamma) \) if and only if \( \Gamma \) can be written as \( \Gamma_1 \lor \Gamma_2 \), where \( \Gamma_1 \) is a disconnected graph on \( n - \kappa(\Gamma) \) vertices and \( \Gamma_2 \) is a graph on \( \kappa(\Gamma) \) vertices with \( \lambda_{n-1}(\Gamma_2) \geq 2\kappa(\Gamma) - n \).

As mentioned earlier, we next show the equivalence of various properties of Laplacian spectra for power graphs of dicyclic groups.

Theorem 13 For any integer \( n \geq 2 \), the following statements are equivalent.

(i) The vertex connectivity and the algebraic connectivity of \( \mathcal{G}(Q_n) \) are equal.

(ii) The algebraic connectivity of \( \mathcal{G}(Q_n) \) is 2.

(iii) The algebraic connectivity of \( \mathcal{G}(Q_n) \) is an integer.

(iv) \( \mathcal{G}(Q_n) \) is Laplacian integral.

(v) \( Q_n \) is generalized quaternion.

Proof Suppose \( \kappa(\mathcal{G}(Q_n)) = \lambda_{4n-1}(\mathcal{G}(Q_n)) \). Then by Lemma 10, \( \mathcal{G}(Q_n) \) can be written as \( \Gamma_1 \lor \Gamma_2 \) for some graphs \( \Gamma_1 \) and \( \Gamma_2 \) with \( \Gamma_1 \) being isomorphic to a disconnected subgraph of \( \mathcal{G}(Q_n) \) on \( 4n - 2 \) vertices. We first show that \( \{ e, a^n \} \) is the
unique minimum separating set of $\mathcal{G}(Q_n)$. Let $S$ be a minimum separating set of $\mathcal{G}(Q_n)$. Assume that $a^n \notin S$. Note that $e \in S$, and in view of Lemma 2, $|S| = 2$. So $S$ contains at most one element of $[a]$. Additionally, as $n \geq 2$, $|[a]| = \phi(2n) \geq 2$. As a result, $\mathcal{G}(\langle a \rangle) - S$ is connected. By following (3) and Lemma 8, all elements of $(\mathcal{G}(Q_n) - \langle a \rangle) - S$ are adjacent to $a^n$. Consequently, $\mathcal{G}(Q_n) - S$ is connected. As this is a contradiction, $S = \{e, a^n\}$. We thus deduce that $\Gamma_1 \cong \mathcal{G}(Q_n) - \{e, a^n\}$ and hence $\mathcal{G}(Q_n) = (\mathcal{G}(Q_n) - \{e, a^n\}) \cup \mathcal{G}(\langle e, a^n \rangle)$. As a result, $a^n$ is adjacent to all other vertices of $\mathcal{G}(Q_n)$. Therefore, by applying Proposition 1 we conclude that $Q_n$ is generalized quaternion. This proves that (i) implies (v).

If $Q_n$ is generalized quaternion, then it follows from Lemma 5 that $\mathcal{G}(Q_n)$ is Laplacian integral. Thus (v) implies (iv). Moreover, (iii) follows trivially from (iv). If (iii) holds, then by Lemma 9, (ii) holds. Finally, considering Lemma 2, (ii) implies (i).

$\square$

3.3 Finite $p$-Group

Throughout this subsection, $p$ denotes a prime number. A $p$-group is a group of order at least two in which order of every element is some power of $p$. For a finite $p$-group $G$, we determine the algebraic connectivity and the multiplicity of the Laplacian spectral radius of $\mathcal{G}(G)$. Then we characterize the equality of the vertex connectivity and the algebraic connectivity of $\mathcal{G}(G)$. Afterwards, we provide iterative methods to obtain the structure and the Laplacian characteristic polynomial of $\mathcal{G}(G)$. We find all possible forms of Laplacian eigenvalues of $\mathcal{G}(G)$, thus showing that it is Laplacian integral.

Let $G$ be a group and $g \in G$. We denote $U(g) = \{h \in G : g \in \langle h \rangle\}$ and $\hat{U}(g) = U(g) - [g]$. Let $\Gamma(g)$ be the subgraph of $\mathcal{G}(G)$ induced by $U(g)$. Moreover, we denote the component of $\mathcal{G}^*(G)$ containing $g$ by $C(g)$. For the above subsets and subgraphs, the underlying group will always be clear from the context.

Since $\Gamma(g)$ is connected, in view of Theorem 2, we have the following remark.

**Remark 1** For any group $G$ and $g \in G$, the multiplicity of the Laplacian eigenvalue 0 of $\Gamma(g)$ is one.

For the rest of this subsection, $G$ denotes a finite $p$-group.

**Lemma 11** If $g$ is an element of order $p$ in $G$, then $C(g) = \Gamma(g)$.

**Proof** Since both $\Gamma(g)$ and $C(g)$ are induced subgraphs of $\mathcal{G}(G)$, we only need to show that their vertex sets are equal. Observe that every element of $U(g)$ is a vertex of $C(g)$. To show the reverse inclusion, let $h$ be a vertex of $C(g)$. By [25, Proposition 3.1], $g$ is adjacent to every other vertex of $C(g)$. In particular, $g$ is adjacent to $h$. Since $o(g)$ is a prime number and $h \neq e$, we have $g \in \langle h \rangle$. Consequently, $h \in U(g)$. This completes the proof of the lemma. $\square$

In the following theorem, when $G$ is neither cyclic nor generalized quaternion, we find the algebraic connectivity and the multiplicity of the Laplacian spectral radius of $\mathcal{G}(G)$. This result, along with Lemmas 4 and 5, provides algebraic connectivity and the multiplicity of Laplacian spectral radius of power graphs of all finite $p$-groups.
Theorem 14 Let the order of $G$ be $n \geq 3$. Then the following statements are equivalent.

(i) The algebraic connectivity of $\mathcal{G}(G)$ is 1.

(ii) The multiplicity of the Laplacian eigenvalue $n$ of $\mathcal{G}(G)$ is one.

(iii) $G$ is neither cyclic nor generalized quaternion.

Proof Lemmas 3 and 6 together show that (i) and (iii) are equivalent.

We next show that (ii) and (iii) are equivalent. Let $G$ be neither cyclic nor generalized quaternion. Then by Lemma 3, $\mathcal{G}^*(G)$ has at least two components. Moreover, from [25, Proposition 3.2], every component of $\mathcal{G}^*(G)$ has exactly $p - 1$ vertices of order $p$. As a result, every component of $\mathcal{G}^*(G)$ has at most $n - p$ vertices. Thus by applying Theorems 5 and 6, we conclude that the Laplacian eigenvalues of $\mathcal{G}^*(G)$ are bounded above by $n - p$. Hence using (1), $\lambda_i(\mathcal{G}(G)) \leq n - p + 1 < n$ for all $2 \leq i \leq n$. Consequently, the multiplicity of the Laplacian eigenvalue $n$ of $\mathcal{G}(G)$ is one.

Conversely, let $G$ be either cyclic or generalized quaternion. Then it follows from Lemmas 4 and 5 that the multiplicity of $n$ is at least two. This completes the proof of the theorem. \hfill \Box

Next we show that the vertex connectivity and the algebraic connectivity of power graph of a finite $p$-group are equal exactly when it is not cyclic.

Theorem 15 Let $G$ be of order $n$. Then $\kappa(\mathcal{G}(G)) = \lambda_{n-1}(\mathcal{G}(G))$ if and only if $G$ is not cyclic.

Proof Let $G$ be cyclic. Then Theorem 1 and Lemma 4 together show that the above equality does not hold.

Now suppose $G$ is not cyclic. If $G$ is generalized quaternion, then by Lemmas 2 and 5, we get $\kappa(\mathcal{G}(G)) = 2 = \lambda_{n-1}(\mathcal{G}(G))$. Whereas, if $G$ is not generalized quaternion, then it follows from Lemmas 3 and 6 that $\kappa(\mathcal{G}(G)) = 1 = \lambda_{n-1}(\mathcal{G}(G))$. \hfill \Box

For $g, h \in G$, we say that $[h]$ is a primitive class of $g$ if $[g] = [hp]$ and $h \neq e$. Clearly, if $[h]$ is a primitive class of $g$, then $[h]$ is a primitive class of $g'$ for any $g' \in [g]$. Note that the condition $h \neq e$ is redundant in the above definition when $g \neq e$. We denote the number of primitive classes of any $g \in G$ by $\pi(g)$.

We notice the simple fact that $G$ being a finite $p$-group, for any $g \in G$, we can not have $\pi(g) = 0$ and $o(g) = 1$ simultaneously.

The proof of the following lemma is straightforward.

Lemma 12 If $g \in G$ with $\pi(g) = 0$, then $\Gamma(g) = \mathcal{G}([g]) \cong K_{\phi(o(g))}$. Consequently, $\Theta(\Gamma(g), x) = x(x - \phi(o(g)))^{\phi(o(g))-1}$.

The following proposition iteratively describes the structure of the power graph of a finite $p$-group.

Proposition 2 Let $g \in G$, $\pi(g) > 0$ and the distinct primitive classes of $g$ be $[h_1], [h_2], \ldots, [h_{\pi(g)}]$. Then

$$\Gamma(g) \cong K_{\phi(o(g))} \lor \left\{ \Gamma(h_1) + \Gamma(h_2) + \cdots + \Gamma(h_{\pi(g)}) \right\}. \quad (4)$$
In particular, for \( g = e \),

\[
\mathscr{G}(G) \cong K_1 \lor \left\{ \Gamma(h_1) + \Gamma(h_2) + \cdots + \Gamma(h_{\pi(e)}) \right\}.
\] (5)

**Proof** Suppose \( o(g) = p^k \) for some integer \( k \geq 0 \). Let \( h \) be a vertex in \( \Gamma(g) \). Then \( p^k \) divides \( o(h) \). If \( o(h) = p^k \), then \( h \in \{g\} \). So let \( o(h) = p^l \) for some integer \( l \geq k \). Then \([h^{p^{l-k-1}}] \) is a primitive class of \( g \). Thus \([h^{p^{l-k-1}}] = [h_i] \), and hence \( h \in U(h_i) \) for some \( 1 \leq i \leq \pi(g) \). Additionally, as \([g] \subset U(g) \) and \( U(h_i) \subset U(g) \) for all \( 1 \leq i \leq \pi(g) \), we have \( U(g) = [g] \cup U(h_1) \cup U(h_2) \cup \cdots \cup U(h_{\pi(g)}) \).

Since every vertex in \([g]\) is adjacent to every other vertex of \( \Gamma(g) \) and \( \mathscr{G}([g]) \cong K_{\phi(o(g))} \), we get \( \Gamma(g) \cong K_{\phi(o(g))} \lor \left\{ \Gamma(h_1) \lor \Gamma(h_2) \lor \cdots \lor \Gamma(h_{\pi(g)}) \right\} \).

For \( \pi(g) = 1 \), the proof of (4) is thus complete. So let \( \pi(g) \geq 2 \) and \( 1 \leq i, j \leq \pi(g) \), \( i \neq j \). If possible, suppose \( h_i, h_j \in \{h\} \) for some \( h \in G \). Since \( \{h\} \) is a clique in \( \mathscr{G}(G) \), \( h_i \) and \( h_j \) are adjacent. Thus, as \( h_i \) and \( h_j \) are of same order, we have \([h_i] = [h_j] \). This is a contradiction. Hence \( \Gamma(h_i) \) and \( \Gamma(h_j) \) have disjoint vertices. Now, if possible, suppose that \( u_i \in U(h_i) \) is adjacent to \( u_j \in U(h_j) \) in \( \mathscr{G}(G) \). Then without loss of generality, taking \( u_i \in \{u\} \), we get \( u_j \in U(h_i) \). As \( \Gamma(h_i) \) and \( \Gamma(h_j) \) have disjoint vertices, the above is a contradiction. We therefore have shown (4). Further, as \( \mathscr{G}(G) = \Gamma(e) \), (5) also follows accordingly. \( \square \)

Applying Theorems 7 and 8 to Proposition 2, we have the following proposition.

**Proposition 3** Let \( g \in G \), \( \pi(g) > 0 \) and the distinct primitive classes of \( g \) be \([h_1], [h_2], \ldots, [h_{\pi(g)}] \). Then

\[
\Theta(\Gamma(g), x) = \frac{x(x - |U(g)|)^{\phi(o(g))}}{x - \phi(o(g))} \prod_{i=1}^{\pi(g)} \Theta(\Gamma(h_i), x - \phi(o(g))).
\] (6)

In particular, for \( g = e \),

\[
\Theta(\mathscr{G}(G), x) = \frac{x(x - |G|)}{x - 1} \prod_{i=1}^{\pi(e)} \Theta(\Gamma(h_i), x - 1).
\] (7)

An irreflexive and transitive binary relation \( \prec \) on a set \( A \) is called **well-founded** if for every non-empty subset \( B \) of \( A \), there exists \( b \in B \) such that there is no \( a \in B \) with \( a \prec b \).

The following theorem is known as **the principle of well-founded induction**.

**Theorem 16** [17, Theorem 6.10] Let \( \prec \) be a well-founded relation on a set \( A \) and \( \mathcal{P} \) be a property defined on the elements of \( A \). Then \( \mathcal{P} \) holds for all elements of \( A \) if and only if the following holds:

- given any \( a \in A \), if \( \mathcal{P} \) holds for all \( b \in A \) with \( b \prec a \), then \( \mathcal{P} \) holds for \( a \).

The following proposition studies the Laplacian spectrum of \( \Gamma(g) \) for any \( g \in G \).
Proposition 4 Let $g \in G$ be an element of order $p^r$, $r \in \mathbb{N}$, such that $\pi(g) > 0$ or $o(g) > 2$. Then every nonzero Laplacian eigenvalue of $\Gamma(g)$ is of the form $o(g_1) - p^{r-1}$ for some $g_1 \in U(g)$ or $|\hat{U}(g_2)| + o(g_2) - p^{r-1}$ for some $g_2 \in U(g)$.

Proof Note that the condition $\pi(g) > 0$ or $o(g) > 2$ eliminates the case $\pi(g) = 0$, $o(g) = 2$. Thus $\Gamma(g)$ has at least one nonzero Laplacian eigenvalue.

Let $p^k$ be the least common multiple of orders of all elements of $G$. As $G$ is a finite $p$-group, this means that it has an element of order $p^k$. Observe that the usual relation $<$ is well-founded on $\{l \in \mathbb{Z} : 0 \leq l \leq k - 1\}$. In order to prove the proposition, we apply the principle of well-founded induction on the above set and prove the following: for any element $g$ of order $p^{k-l}$, every nonzero Laplacian eigenvalue of $\Gamma(g)$ is of the form $o(g_1) - p^{k-l-1}$ for some $g_1 \in U(g)$ or $|\hat{U}(g_2)| + o(g_2) - p^{k-l-1}$ for some $g_2 \in U(g)$.

If $g$ is an element of order $p^k$, then $\pi(g) = 0$. Thus $o(g) - p^{k-1} = |\hat{U}(g)| + o(g) - p^{k-1} = \phi(p^k)$, and by Lemma 12, this is the only Laplacian eigenvalue of $\Gamma(g)$. This proofs our claim for $l = 0$. In fact, if $k = 1$, then the proof is complete. So let $k > 1$.

We now assume that the assertion holds for $l = m$, $0 \leq m \leq k - 2$, and show it for $l = m + 1$.

Let $g$ be an element of order $p^{k-(m+1)}$. If $\pi(g) = 0$, then the statement holds for $l = m + 1$ by an argument similar to the case when $g$ is of order $p^k$. Now let $\pi(g) > 0$ and the distinct primitive classes of $g$ be $[h_1], [h_2], \ldots, [h_{\pi(g)}]$. Observe that for every $1 \leq i \leq \pi(g)$, $o(g) - p^{k-m-2} = \phi(p^{k-m-1})$ is a root of $\Theta((\Gamma(h_i), x - \phi(p^{k-m-1})))$. Additionally, as $g \neq e$, $o(h_i) > 2$ for all $1 \leq i \leq \pi(g)$. Thus in view of the induction hypothesis, every root of $\Theta((\Gamma(h_i), x - \phi(p^{k-m-1})))$, other than $o(g) - p^{k-m-2}$, is of the form $o(g_1) - p^{k-m-2}$ for some $g_1 \in U(h_i)$ or $|\hat{U}(g_2)| + o(g_2) - p^{k-m-2}$ for some $g_2 \in U(h_i)$. We also note that $|U(g)| = |\hat{U}(g)| + o(g) - p^{k-m-2}$. Hence, application of (6) proves the assertion for $l = m + 1$. This completes the proof of the proposition.

Now we provide all possible forms of Laplacian eigenvalues of $\mathcal{G}(G)$ and conclude that it is Laplacian integral.

Theorem 17 Every Laplacian eigenvalue of $\mathcal{G}(G)$ is among $0$, $o(g)$ for some $g \in G$ or $|\hat{U}(h)| + o(h)$ for some $h \in G$. In particular, $\mathcal{G}(G)$ is Laplacian integral.

Proof Trivially, $|\hat{U}(e)| + o(e) = n$. Let the distinct primitive classes of $e$ be $[g_1], [g_2], \ldots, [g_{\pi(e)}]$. Then by Proposition 4, if $\pi(g_i) > 0$ or $o(g_i) > 2$ for any $1 \leq i \leq \pi(e)$, then every nonzero root of $\Theta((\Gamma(g_i), x - 1))$ is of the form $o(h_1)$ for some $h_1 \in U(g_i)$ or $|\hat{U}(h_2)| + o(h_2)$ for some $h_2 \in U(g_i)$. Moreover, for every $1 \leq i \leq \pi(e)$, $1$ is a root of $\Theta((\Gamma(g_i), x - 1))$. Hence by applying (7), the proof follows.

Remark 2 For any $g \in G$, $|\hat{U}(g)| + o(g) = o(g)$ if and only if $\pi(g) = 0$.

In the following, we give some properties of the Laplacian eigenvalue $|\hat{U}(g)| + o(g)$.

Proposition 5 For any $g \in G$, the following statements hold.

(i) $|\hat{U}(g)| + o(g)$ is a multiple of $o(g)$.

\( \square \) Springer
(ii) If \(|\hat{U}(g)| + o(g)\) is a prime power, then \(\pi(g) = 0\) or \(\pi(g) \equiv 1 \pmod{p}\).

**Proof** Let \(o(g) = p^k\) for some \(k \in \mathbb{N}\).

(i) If \(\pi(g) = 0\), then \(|\hat{U}(g)| + o(g) = p^k\). Now let \(\pi(g) > 0\). Then in view of Proposition 2, there exist positive integers \(a_1, \ldots, a_l\) with \(a_1 = \pi(g)\) such that

\[
|U(g)| = \phi(p^k) + a_1\phi(p^{k+1}) + \cdots + a_l\phi(p^{k+l})
\]

\[
\Rightarrow |\hat{U}(g)| + o(g) = p^k + a_1\phi(p^{k+1}) + \cdots + a_l\phi(p^{k+l}).
\]  

Thus we have shown (i).

(ii) Let \(|\hat{U}(g)| + o(g) = p^m\) for some \(m \in \mathbb{N}\). If \(m = k\), then \(\pi(g) = 0\). Now let \(m > k\). Then we have \(\pi(g) > 0\). Comparing both sides of (8), we thus get \(p | (a_1 - 1)\).

This proves (ii). \(\square\)

Using Theorem 17 and Proposition 5(i), we have the following corollary.

**Corollary 1** Any nonzero Laplacian eigenvalue of \(\mathscr{G}(G)\) is 1 or multiple of the order of a non-identity element of \(G\). In particular, it is 1 or multiple of a positive power of \(p\).

We conclude this subsection with the following proposition, which also serves as an illustration for some of the above results.

**Proposition 6** If \(G\) is a group of order \(p^2\), then the Laplacian spectrum of \(\mathscr{G}(G)\) is either

\[
\begin{pmatrix} 0 & p^2 \\ 1 & p^2 - 1 \end{pmatrix} \text{ or } \begin{pmatrix} 0 & 1 \\ 1 & p(p+1)(p-2) \end{pmatrix}.
\]

**Proof** As already recalled in Lemma 4, if \(G\) is cyclic, then the Laplacian spectrum of \(\mathscr{G}(G)\) is \(\begin{pmatrix} 0 & p^2 \\ 1 & p^2 - 1 \end{pmatrix}\). It is known that any group of order \(p^2\) is abelian (cf. [27]). Thus, if \(G\) is not cyclic, then \(G \cong \mathbb{Z}_p \times \mathbb{Z}_p\). In \(\mathbb{Z}_p \times \mathbb{Z}_p\), the distinct primitive classes of \((\overline{0}, \overline{0})\) are \(((\overline{0}, \overline{T}), ((\overline{T}, \overline{0}), ((\overline{T}, \overline{T}), ((\overline{T}, \overline{2}) \ldots, ((\overline{T}, \overline{p-1})\). Moreover, we observe that each of these classes induce subgraphs isomorphic to \(K_{p-1}\) in \(\mathscr{G}(\mathbb{Z}_p \times \mathbb{Z}_p)\). Hence by applying (7), we get

\[
\Theta(\mathscr{G}(G), x) = \frac{x(x - p^2)}{x - 1} \{\Theta(K_{p-1}, x - 1)\}^{p+1} = x(x - 1)^p (x - p)^{(p+1)(p-2)}(x - p^2).
\]

This proves the proposition. \(\square\)

**4 Conclusion**

In this article, we obtained characterization of the equality of vertex and algebraic connectivity of power graphs of \(\mathbb{Z}_n, \mathbb{Q}_n\) and finite \(p\)-groups. Providing a group theoretic characterization of the above equality for all finite groups is still open for study.
Moreover, we proved that the power graph of $Q_n$ is Laplacian integral if and only if $Q_n$ is generalized quaternion, and that the power graph of a finite $p$-group is always Laplacian integral. Based on our observations, we state the following for $\mathbb{Z}_n$.

**Conjecture 1** For any integer $n \geq 2$, the following statements are equivalent.

(i) The algebraic connectivity of $\mathcal{G}(\mathbb{Z}_n)$ is an integer.

(ii) $\mathcal{G}(\mathbb{Z}_n)$ is Laplacian integral.

(iii) $n$ is a prime power or product of two primes.
