ABSTRACT

Generalized $\mathcal{Z}_k^{(r/2)}$ parafermionic theories – characterized by the dimension $(r/2)(1-1/k)$ of the basic parafermionic field – provide potentially interesting quantum-Hall trial wavefunctions. Such wavefunctions reveal a $\mathcal{W}_k$ structure. This suggests the equivalence of (a subclass of) the $\mathcal{Z}_k^{(r/2)}$ models and the $\mathcal{W}_k(k+1,k+r)$ ones. This is demonstrated here for $r=3$ (the gaffnian series). The agreement of the parafermionic and the $\mathcal{W}$ spectra relies on the prior determination of the field identifications in the parafermionic case.

1 Introduction

An interesting application of conformal field theory to the fractional quantum Hall effect is that CFT correlators can be used as trial wavefunctions [1]. In this way, the Read-Rezayi states [2] are related to the usual $\mathcal{Z}_k$ parafermionic theories [3]. A natural extension is to consider the $\mathcal{Z}_k^{(r/2)}$ generalized parafermionic models to generate new classes of trial wavefunctions. Here the parameter $r$ is an integer $\geq 2$ that specifies the conformal dimension of the parafermionic fields $\psi_n$ to be [3]

$$h_{\psi_n}^{(r/2)} = \frac{rn(k-n)}{2k} \quad \text{(where } rk \in 2\mathbb{N}),$$

with $\mathcal{Z}_k^{(1)} \equiv \mathcal{Z}_k$. The $\mathcal{Z}_k^{(3/2)}$ parafermionic theories have been introduced in [4]; their $k=2$ correlators are related to the so-called gaffnian states [5].

Up to exponential terms, the (bosonic) quantum-Hall wavefunction is a symmetric polynomial. Wavefunctions with prescribed parafermionic-type clustering properties (vanishing with power $r$ when $k+1$ coordinates approach each other) happen to be given by particular Jack polynomials with parameter $\alpha = -(k+1)/(r-1)$ and partitions with difference $r$ at distance $k$ [7, 9]. These are precisely the Jack polynomials that were conjectured to be related to the minimal models $\mathcal{W}_k(k+1,k+r)$ [10]. Evidences for this Jack-$\mathcal{W}$ relationship are presented in [8]. This connection has been further substantiated in [9], where in particular the central charge of the CFT related to these special Jack wavefunctions is computed directly. As expected, the underlying CFT displays the clear characteristics of a $\mathcal{Z}_k^{(r/2)}$ theory.

These considerations suggest the general CFT equivalence

$$\mathcal{Z}_k^{(r/2)} \simeq \mathcal{W}_k(k+1,k+r),$$

(already hinted at in [4]). This relation incorporates the well-established unitary $\mathcal{W}$ representation of the usual $\mathcal{Z}_k$ models [14]. This correspondence is also verified for $k=2$ [15] where (2) reduces to $\mathcal{Z}_2^{(r/2)} \simeq \mathcal{M}(3,r+2)$, in which

---

1 The $\mathcal{Z}_k^{(2)}$ models have been studied in [11] for $k=3$ and in [12] for arbitrary $k$ (but in both cases, only for the unitary series), while the $\mathcal{Z}_3^{(4)}$ model has been constructed in [13].

2 As shown below, the $\mathcal{Z}_3^{(3/2)}$ model is indeed equivalent to the $\mathcal{M}(3,5)$ minimal model, the CFT underlying the gaffnian states. The later is also the first member of yet another parafermionic sequence, the so-called graded parafermionic theories, related to the coset $\mathbb{O}(1,2)_{k}/\mathbb{U}(1)$ [6].
case, the parafermion $\psi_1$, of dimension $r/4$, is identified with the minimal-model primary field $\phi_{2,1}$. However, for $r \geq 4$ and $k > 2$, (2) is incomplete since the central charge of the parafermionic theory does not appear to be fixed. This relation should thus be understood as restricted to a particular non-unitary sector (or minimal series) of the parafermionic models, a sector selected by the assumed properties of the basic parafermionic correlation function. Alternatively, it states that these particular $W_k$ models have a reformulation in terms of $\mathcal{Z}_k^{(3/2)}$ parafermions.

Apart from the $k = 2$ or $r = 2$ cases, there is another instance where the equivalence (2) should be satisfied without restriction and this is when $r = 3$. As for their $r = 2$ counterparts, the central charge of the $\mathcal{Z}_k^{(3/2)}$ models is uniquely fixed by associativity; it reads

$$c = -\frac{3(k-1)^2}{(k+3)}.$$  \hfill (3)

This is the first indication of the equivalence:

$$\mathcal{Z}_k^{(3/2)} \simeq W_k(k+1, k+3).$$  \hfill (4)

This relation was pointed out in [4] and claimed to hold in the simplest cases, albeit without the presentation of a detailed supporting analysis. This statement relied on the equality of the central charges and the fact that the $W$ primary fields were contained in the set of parafermionic primary fields and the top fields of different charge modulo $k$ among the parafermionic descendants. However, this verification did not rest on the analysis of the field identifications in the parafermionic models. This is remedied here, where at first the field identifications in the $\mathcal{Z}_k^{(3/2)}$ model are obtained, and then used to verify the perfect correspondence between the spectra of the two theories in (4).

2 The $\mathcal{Z}_k^{(3/2)}$ parafermionic theory

2.1 Structure of the $\mathcal{Z}_k^{(3/2)}$ algebra

Let us first briefly review the basic elements of the $\mathcal{Z}_k^{(3/2)}$ parafermionic models [4]. As for any $\mathcal{Z}_k$ theory, there are $k$ sectors labeled by integers $t = 0, \cdots, k-1$. The mode decomposition of $\psi_1$ in the sector $t$, reads

$$\psi_1(z) = \sum_{m=-\infty}^{\infty} z^{-\frac{r}{2} - m - 1} A_{m+1} + \frac{1}{2} + \frac{2}{k} = \sum_{m=-\infty}^{\infty} z^{-\lambda q - m - 1} A_{m - \frac{1}{2} + \lambda(1+q)} ,$$  \hfill (5)

where

$$t = \frac{3q}{2}, \quad \lambda = \frac{3}{2k}.$$  \hfill (6)

A similar expression holds for the decomposition of $\psi_1^t$ with $q \rightarrow -q$. The charge $q$ is normalized by setting that $A$ to be 2 (or its $t$ value is 3). It is convenient to write

$$A_{u+\lambda(1+q)} = A_u \quad \text{and} \quad A^t_{u+\lambda(1-q)} = A^t_u ,$$  \hfill (7)

where $u$ is half-integer. With this notation the commutation relations reads (when acting on a state in the $t$ sector):

$$\sum_{l=0}^{\infty} \binom{l+2\lambda - 1}{l} \left[ A_{n-l} A^t_{m+l} + \frac{1}{2} - A^t_{m-l} A_{n+l} - t \right] = \frac{(k+3)}{k(k-1)} L_{n+m} + \frac{1}{2} (n + \lambda q)(n - 1 + \lambda q) \delta_{n+m,0} .$$  \hfill (8)

(The coefficient of the Virasoro mode is actually $2h_1/c$, where $h_1 = 3(k-1)/(2k)$, the dimension of $\psi_1$; associativity fixes $c$ to the value (3), which has been substituted here.) In addition, one has

$$\sum_{l=0}^{\infty} \binom{l-2\lambda - 1}{l} \left[ A_{n-l} A^t_{m+l} + \frac{1}{2} - A^t_{m-l} A_{n+l} - t \right] = 0 ,$$  \hfill (9)

with an identical expression with $A$ replaced by $A^t$. \hfill 2
2.2 Aspects of the representation theory

The highest-weight states are defined by the conditions:

\[ A_{m+\frac{1}{2}} |\text{hws}\rangle = A_{m+\frac{1}{2}}^\dagger |\text{hws}\rangle = 0 \quad \text{for} \quad m \geq 0. \]  

They are characterized by \( t \) and a further quantum number \( s \) (called \( r \) in [4]):

\[ |\text{hws}\rangle \equiv |t, s\rangle. \]  

The parameter \( s \) enters in the expression of the basic singular vectors (i): \((A_{-\frac{3}{2}})^{s+1} |t, s\rangle\) and (ii): \((A_{-\frac{3}{2}}^\dagger)^{t+s+1} |t, s\rangle\),

\[ h_{t,s} = -\frac{k(k - 2s - t - 1)(2s + t) + t^2}{2k(k + 3)}. \]  

The corresponding primary field will be denoted \( \phi_{t,s} \). The state with \( t = s = 0 \) has \( h = 0 \), so that it can be identified with the vacuum (i.e., \( \phi_{0,0} = I \)). In addition, we find the singular vectors (i): \((A_{-\frac{3}{2}})^{k-t-2s+1} |t, s\rangle\) and (ii): \((A_{-\frac{3}{2}}^\dagger)^{k-t+1} (A_{-\frac{3}{2}}^\dagger)^{t+s} |t, s\rangle\),

\[ \mathcal{A}_{\frac{1}{2}} |\chi\rangle = 0 = \mathcal{A}_{\frac{1}{2}}^\dagger |\chi\rangle, \]  

instead of (10) (which signals that these singular vectors are actually descendants of a lower dimensional singular vector involving Virasoro modes [4]). These conditions will be sufficient for our purpose.

By definition, \( s \) has to be a non-negative integer while from (14), we deduce that \( 0 \leq s \leq (k - t)/2 \). However, the bounds:

\[ 0 \leq t \leq k - 1 \quad \text{and} \quad 0 \leq s \leq \left\lfloor \frac{k - t}{2} \right\rfloor \]  

(where \( \lfloor x \rfloor \) is the integer part of \( x \)), are not optimal: not each allowed value of \((t, s)\) corresponds to an independent field.

2.3 Field identifications

In order to obtain a set of field identifications, we use as a guiding principle the observation that for the usual \( \mathbb{Z}_k \) models, these involve fields associated to states at the inner border of the sequences defining the singular vectors [16]. In this way, we readily obtain the identifications:

\[ (A_{-\frac{3}{2}})^{k-t} |t, 0\rangle \sim |k - 2t, t\rangle \]  

\[ (A_{-\frac{3}{2}})^{k-2s} (A_{-\frac{3}{2}}^\dagger)^{s} |0, s\rangle \sim |k - 3s, s\rangle \]  

\[ (A_{-\frac{3}{2}}^\dagger)^{t+s} |t, s\rangle \sim |k - 2t - 3s, s + t\rangle \]  

with the requirements that the two entries \( t', s' \) specifying a state need to be positive integers (e.g., in the second case, we require \( k - 3s \geq 0 \)). In each case, the equality of the dimensions and the charges (modulo \( k \)) is verified.

The lhs of the two first identifications are two special cases of the one-before-last state of the sequence (14i) (for \( s = 0 \) and \( t = 0 \) respectively). Similarly, the lhs of (17c) is related to the penultimate state in the sequence (12ii). The remaining two sequences, (12i) and (14ii), do not lead to state identifications.

The identifications (17a)-(17c) are established as follows: one acts on the lhs by either \( A_{-\frac{3}{2}} \) (in the first two cases) or \( A_{-\frac{3}{2}}^\dagger \) (in the third one) to generate a singular vector that is set equal to zero. The same action on the rhs
becomes either $A_{\frac{1}{2}}$ or $A_{\frac{1}{2}}^\dagger$ respectively, which is nothing but a highest-weight condition. For instance, in the second case, one has
\begin{equation}
A_{-\frac{1}{2}}(A_{-\frac{1}{2}})^{k-2s}(A_{-\frac{1}{2}})^s|0, s\rangle = A_{-\frac{1}{2} + \frac{1}{2}(1 + \frac{1}{2}(3k-3s))}(A_{-\frac{1}{2}})^{k-2s}(A_{-\frac{1}{2}})^s|0, s\rangle = 0. \tag{18}
\end{equation}
When acting on the rhs, this becomes
\begin{equation}
A_{-\frac{1}{2} + \frac{1}{2}(1 + \frac{1}{2}(3k-3s))}|k - 3s, s\rangle = A_{-\frac{1}{2} + \frac{1}{2}(1 + \frac{1}{2}(3k-3s))}|k - 3s, s\rangle = A_{\frac{1}{2}}|k - 3s, s\rangle = 0. \tag{19}
\end{equation}
In addition to these series of identifications, one has the following sequence
\begin{equation}
(A_{-\frac{1}{2}})^{k-t-2s}(A_{-\frac{1}{2}}^\dagger)^s|t, s\rangle \sim (A_{-\frac{1}{2}}^\dagger)^{t+s}|t, s\rangle, \tag{20}
\end{equation}
which merely reflects the $Z_k$ cyclic symmetry, expressed here as a state identification in its most general form. In particular, it implies that the identification (17a) is a special case of (17c). The condition (20) also entails $(A_{-\frac{1}{2}})^k|0, 0\rangle \sim |0, 0\rangle$ and $(A_{-\frac{1}{2}}^\dagger)^{k-2}|0, 0\rangle \sim |0, 0\rangle$.

3 Generalities concerning the $\mathcal{W}_k(p', p)$ model

In view of establishing the equivalence (4), let us first recall some results on $\mathcal{W}_k(p', p)$ models [17]. The primary fields $\phi^{(\hat{\lambda}, \hat{\mu})}$ are labeled by two integrable $su(k)$ weights $\hat{\lambda}$ and $\hat{\mu}$ at respective level $p' - k$ and $p - k$ (with say $p > p'$). Their conformal dimension reads
\begin{equation}
h_{\{\hat{\lambda}, \hat{\mu}\}} = \frac{|p(\lambda + \rho) - p'(\mu + \rho)|^2 - (p - p')^2|\rho|^2}{2pp'}, \tag{21}
\end{equation}
where $\lambda$ stands for the finite weight associated to $\hat{\lambda}$ and $\rho$ is the Weyl vector (we follow the notation of [18]):
\begin{equation}
\hat{\lambda} = \sum_{i=0}^{k-1} \lambda_i \hat{\omega}_i = [\lambda_0, \lambda_1, \cdots, \lambda_{k-1}], \quad \hat{\mu} = \sum_{i=0}^{k-1} \hat{\omega}_i = [1, 1, \cdots, 1], \tag{22}
\end{equation}
Recall also the $\mathcal{W}$ field identifications [17]:
\begin{equation}
\{\hat{\lambda}, \hat{\mu}\} \sim \{a\hat{\lambda}, a\hat{\mu}\} \sim \cdots \sim \{a^{k-1}\hat{\lambda}, a^{k-1}\hat{\mu}\}, \tag{23}
\end{equation}
where $a$ is the basic $su(k)$ automorphism that permutes the Dynkin labels:
\begin{equation}
a[\lambda_0, \lambda_1, \cdots, \lambda_{k-1}] = [\lambda_{k-1}, \lambda_0, \cdots, \lambda_{k-2}]. \tag{24}
\end{equation}
The central charge of the $\mathcal{W}_k(p', p)$ model is
\begin{equation}
c = (k - 1) \left(1 - \frac{k(k+1)(p - p')^2}{pp'}\right) \tag{25}
\end{equation}
and with $(p', p) = (k + 1, k + 3)$, this reduces to (3). This completes the first step of the verification of (4).

In preparation for the next step, note that for $(p', p) = (k + 1, k + 3)$, $\hat{\lambda} \in P^1_+$ and $\hat{\mu} \in P^3_+$, with $P^m_+$ denoting the set of integrable weights at level $m$. Thanks to the field identifications (23), we can choose the field representatives to be all of the form:
\begin{equation}
\{(1, 0, \cdots, 0), \hat{\mu}\} = \{\hat{\omega}_0, \hat{\mu}\}, \tag{26}
\end{equation}
with $\hat{\mu}$ running over the complete set $P^3_+$. We will thus designate the $\mathcal{W}$ fields solely by $\hat{\mu}$. Note that by acting with $a^n$ only on $\hat{\mu}$ does produce distinct fields for $n < k$.

4 $\mathcal{Z}_k^{(3/2)}$ vs the $\mathcal{W}_k(k + 1, k + 3)$ model

The next step amounts to compare the spectrum of the two theories. Since it is not clear at once how the $\mathcal{W}$ primary fields get reorganized in terms of parafermionic families, it is more appropriate at this point to first perform an explicit analysis for the lowest values of $k$, e.g., $k = 2, 4$ and 6.
4.1 $k = 2$

The $\mathcal{W}_2(3,5)$ model is nothing but the minimal model $\mathcal{M}(3,5)$ with central charge $-3/5$. With their conformal dimension indicated by an attached subscript, the $\mathcal{W}_2(3,5)$ fields, designated by $\hat{\mu}$, are:

$$[3,0]_0, \quad [0,3]_{\frac{4}{5}}, \quad [2,1]_{\frac{3}{5}}, \quad [1,2]_{\frac{5}{5}}.$$ (27)

States have been ordered in orbits of $a$ (here of length 2). These dimensions match those of the parafermionic states:

$$[0,0], \quad A_{\frac{3}{2}}[0,0], \quad [1,0], \quad A_{\frac{5}{2}}[1,0].$$ (28)

We see that the parafermion acts as the simple current (as $a$). To be fully explicit: the state $[0,0]$ has already been identified with the vacuum, while for the state $[1,0]$, we have

$$h_{t,0} = -\frac{t(k-t)(k-1)}{2k(k+3)} \quad (k=2, t=1) \quad h_{1,0} = -\frac{1}{20}. \quad (29)$$

The dimensions of the second and the fourth states are computed as

$$A_{\frac{3}{2}}[0,0] = A_{\frac{5}{2} + \frac{4}{5}(1+\frac{5}{2})}[0,0] = A_{\frac{5}{2}}[0,0] \quad \text{and} \quad A_{\frac{5}{2}}[1,0] = A_{\frac{5}{2} + \frac{4}{5}(1+\frac{5}{2})}[1,0] = A_{\frac{5}{2}}[1,0],$$ (30)

giving then respectively $3/4$ and $1/4 + h_{1,0} = 1/5$.

These correspondences suggest that the first and the third states in (28) are the only two parafermionic primary fields. However, the bounds (16) allow also the solution: $t = 0, s = 1$. From the expression of $h_{t,s}$ in (13), we have

$$h_{0,s} = -\frac{s(k-2s-1)}{(k+3)} \quad (k=2, s=1) \quad h_{0,1} = \frac{1}{5}. \quad (31)$$

This state is identified as follows (cf. (17a) with $k = 2, t = 1$): $|0,1\rangle \sim A_{\frac{5}{2}}[1,0]$. Its $A_{\frac{5}{2}}$ ‘descendant’ is

$$A_{\frac{5}{2}}[0,1] = A_{\frac{5}{2} + \frac{4}{5}(1+0)}[0,1] = A_{\frac{5}{2}}[0,1] : \quad h = -\frac{1}{4} + \frac{1}{5} = -\frac{1}{20},$$ (32)

so that $A_{\frac{5}{2}}[0,1] \sim |1,0\rangle$. This exhausts the spectrum.

4.2 $k = 4$

The different primary fields of the $\mathcal{W}_4(5,7)$ model are:

$$[3,0,0,0]_0 \quad [0,3,0,0]_{\frac{4}{5}} \quad [0,0,3,0]_{\frac{3}{5}} \quad [0,0,0,3]_{\frac{7}{5}}$$
$$[2,1,0,0]_{\frac{9}{5}} [0,2,1,0]_{\frac{9}{5}} [0,0,2,1]_{\frac{4}{5}} [1,0,0,2]_{\frac{14}{5}}$$
$$[2,0,1,0]_{\frac{14}{5}} [0,2,0,1]_{\frac{14}{5}} [1,0,2,0]_{\frac{7}{5}} [0,1,0,2]_{\frac{14}{5}}$$
$$[2,0,0,1]_{\frac{14}{5}} [1,2,0,0]_{\frac{7}{5}} [0,1,2,0]_{\frac{4}{5}} [0,0,1,2]_{\frac{7}{5}}$$
$$[1,1,0,1]_{\frac{4}{5}} [1,1,1,0]_{\frac{14}{5}} [0,1,1,1]_{\frac{7}{5}} [1,0,1,1]_{\frac{4}{5}}$$ (33)

The $\mathcal{W}$ fields have been organized (horizontally) in orbits of the outer automorphism with $\sigma^n$ ($n = 0, 1, 2, 3$). For each orbit, the lowest-dimensional field has been placed at the left-most position. Again, this action of the outer automorphism is that of a simple current which is the parafermion itself.

The states in the first row are thus described by the string

$$(A_{\frac{3}{2}})^n|0,0\rangle \quad \text{with} \quad |0,0\rangle \sim [3,0,0,0] \quad \text{and} \quad n = 0,1,2,3.$$ (34)

We can thus associate the four states on the top row with the fields $\psi_n$, with $n = 0, 1, 2, 3$ respectively. Let us now compare the conformal dimensions of the parafermionic highest-weight state with that of the left-most state in the following three rows under the assumption that these all have $s = 0$:

$$h_{t,0} = -\frac{t(k-t)(k-1)}{2k(k+3)} \quad (k=4) \quad h_{1,0} = h_{3,0} = -\frac{9}{56}, \quad h_{2,0} = -\frac{3}{14}. \quad (35)$$
That shows that we can identify the spin field $\phi_{t,0}$ with the $W$ field whose finite weight $\mu$ is the fundamental weight $\omega_1$. The other states in these rows are described by the orbits:

$$\left(\mathcal{A}_{-\frac{3}{2}}\right)^n[t,0] \text{ with } 0 \leq n \leq 4 - t \quad \text{and} \quad \left(\mathcal{A}_{-\frac{1}{2}}\right)^m[t,0] \text{ with } 1 \leq m \leq t - 1,$$

which are within the bounds fixed by the singular vectors (12) and (14). When a singular vector is hit with the first sequence (namely when the Dynkin label 1 precedes the 2), one restarts with the other one. The first descendant state generated from the second string is the one at the far right state. Indeed $\mathcal{A}^t$ acts as $a^{-1}$. Note that the above bounds on $n$ and $m$ could be modified as $0 \leq n \leq 3 - t$ and $1 \leq m \leq t$ due to the field identification (20).

All the states considered so far have $s = 0$ and there is no room left for further such states. But we still have to properly identify the states in the last row. Let us then see how we could interpret its left-most state, of dimension $Z_{10}W$. We thus find a perfect agreement between the spectra of the $W$ fields. However, since there are no more $W$ fields, the remaining $|t, s\rangle$ states, namely $|0, 2\rangle$, $|1, 1\rangle$ and $|2, 1\rangle$, should be related to states already obtained. Indeed, one has

$$|0, 2\rangle \sim \left(\mathcal{A}_{-\frac{1}{2}}\right)^2|2, 0\rangle \quad \text{[by (17a)]}$$
$$|1, 1\rangle \sim \left(\mathcal{A}_{-\frac{1}{2}}\right)^2\left(\mathcal{A}_{-\frac{1}{2}}\right)|0, 1\rangle \quad \text{[by (17b)]}$$
$$|2, 1\rangle \sim \left(\mathcal{A}_{-\frac{1}{2}}\right)^3|1, 0\rangle \quad \text{[by (17a)].}$$

We thus find a perfect agreement between the spectra of the $Z_{4}^{(3/2)}$ and the $W_5(5, 7)$ models.

### 4.3 $k = 6$

The set of $W_{6}(7, 10)$ fields can be organized in terms of 10 orbits. The fields specified by the lowest dimensional member of its orbit (except in the penultimate case) – with the comas between the Dynkin labels omitted –, followed
by the dimensions of 6 orbit members are:

\[
\begin{array}{cccccccc}
[300000] : & 0 & \frac{5}{4} & 2 & \frac{9}{4} & 2 & \frac{5}{4} & (A_{-\frac{1}{2}})^5|0, 0) \\
[210000] : & -\frac{25}{108} & \frac{23}{27} & \frac{155}{108} & \frac{11}{27} & \frac{118}{108} & \frac{5}{27} & (A_{-\frac{1}{2}})^3|1, 0) \\
[201000] : & -\frac{10}{27} & \frac{59}{108} & \frac{26}{27} & \frac{95}{108} & \frac{8}{27} & \frac{23}{108} & (A_{-\frac{1}{2}})^4|2, 0) , (A_{-\frac{1}{2}})^5|2, 0) \\
[200100] : & \frac{5}{27} & \frac{5}{4} & \frac{7}{27} & \frac{1}{3} & \frac{7}{12} & \frac{1}{3} & (A_{-\frac{1}{2}})^3|3, 0) , (A_{-\frac{1}{2}})^2|3, 0) \\
[200010] : & -\frac{10}{27} & \frac{23}{108} & \frac{8}{27} & \frac{95}{108} & \frac{26}{27} & \frac{59}{108} & (A_{-\frac{1}{2}})^2|4, 0) , (A_{-\frac{1}{2}})^3|4, 0) \\
[200001] : & -\frac{25}{108} & \frac{5}{27} & \frac{5}{108} & \frac{41}{27} & \frac{155}{108} & \frac{23}{27} & (A_{-\frac{1}{2}})^2|5, 0) , (A_{-\frac{1}{2}})^4|5, 0) \\
[110001] : & -\frac{1}{4} & -\frac{1}{12} & \frac{2}{3} & \frac{11}{12} & \frac{2}{3} & -\frac{1}{12} & (A_{-\frac{1}{2}})^4A_{-\frac{1}{2}}|0, 1) \\
[101001] : & -\frac{25}{108} & -\frac{37}{108} & \frac{27}{108} & \frac{11}{108} & -\frac{1}{108} & \frac{2}{27} & (A_{-\frac{1}{2}})^3A_{-\frac{1}{2}}|1, 1) , (A_{-\frac{1}{2}})^2|1, 1) \\
[100101] : & -\frac{7}{27} & -\frac{37}{108} & \frac{27}{108} & \frac{11}{108} & \frac{35}{108} & (A_{-\frac{1}{2}})^2A_{-\frac{1}{2}}|2, 1) , (A_{-\frac{1}{2}})^3|2, 1) \\
[101010] : & -\frac{2}{9} & \frac{1}{36} & (A_{-\frac{1}{2}})^0|0, 2) \\
\end{array}
\]

At the right of each row, we have given the corresponding parafermionic states as a sequence of operators acting on the parafermionic primary state. When two sequences are written, we recall that $A^\dagger$ acts as $a^{-1}$ so that the outer automorphism action is toward the right. For instance we have:

\[
(A_{-\frac{1}{2}})^2|2, 0) = A_{-\frac{1}{2}}A_{-\frac{1}{2}}|2, 0) \sim [002010], \quad h = \frac{5}{12} + \frac{11}{12} - \frac{10}{27} = \frac{26}{27}, \quad t = 2 + 6 = 2 \text{ (mod 6)}
\]

\[
(A_{-\frac{1}{2}})^2|2, 1) = A_{-\frac{1}{2}}A_{-\frac{1}{2}}|2, 1) \sim [010110], \quad h = \frac{1}{12} + \frac{7}{12} = \frac{11}{27}, \quad t = 2 - 6 = 2 \text{ (mod 6).}
\]

The $t$ assignments are in agreement with the expression (39). The last row displays a feature encountered for all values of $k$ that are multiple of 3: a short orbit that results from the existence of fixed points under the action of some power of $a$ (here $a^2$).

The missing parafermionic primary states are taken into account by the following identifications:

\[
|4, 1) \sim (A_{-\frac{1}{2}})^5|1, 0) \quad \text{[by (17a)]}
\]

\[
|2, 2) \sim (A_{-\frac{1}{2}})^4|2, 0) \quad \text{[by (17a)]}
\]

\[
|0, 3) \sim (A_{-\frac{1}{2}})^5|3, 0) \quad \text{[by (17a)]}
\]

\[
|3, 1) \sim (A_{-\frac{1}{2}})^4A_{-\frac{1}{2}}|0, 1) \quad \text{[by (17b)]}
\]

\[
|1, 2) \sim (A_{-\frac{1}{2}})^3|1, 1) \quad \text{[by (17c)].}
\]

This completes the verification of the spectrum equivalence of the $Z_6^{(3/2)}$ and the $W_0(7, 9)$ models.

### 4.4 Generic even $k$

With $k$ generic, we can easily verify the following correspondences. The parafermion $\psi_{\mu}$ is associated to the field whose finite weight $\mu = 2\omega_i$, whose conformal dimension is $(3n/2)(1 - n/k)$. Similarly, the spin field $\phi_{t, 0}$ corresponds to that with weight $\mu = \omega_t$, whose dimension equals $h_{t, 0}$. The description of its orbit in terms of parafermionic descendants is readily verified.

$W_k$ primary fields with $0 \leq \mu_i \leq 1$ ($i = 0, \cdots, k - 1$) (that is, with three affine Dynkin labels equal to 1) correspond to parafermionic states with $s \neq 0$. The corresponding parafermionic primary state has $\mu_0 = 1$; with $i, j$ standing for the positions of its non-zero finite Dynkin labels, its value of $s$ reads

\[
s = \frac{1}{2}(k - t - |i - j|) .
\]
This is easily checked to be integer: $k$ is even, $t$ is $i + j$ modulo $k$, and $|i - j| = i - j$ modulo 2. This expression for $s$ is verified in the previous case ($k = 2, 4, 6$). For $k = 8$, here are some correspondences:

\[
\begin{align*}
[11000001]_{\text{wt}} & : [0, 1] & [10100010]_{\text{wt}} & : [0, 2] & [10010100]_{\text{wt}} & : [0, 3] \\
[10001011]_{\text{wt}} & : [0, 4] & [10100001]_{\text{wt}} & : [1, 1] & [10010001]_{\text{wt}} & : [2, 1].
\end{align*}
\] (45)

Let us conclude by comparing the number of orbits in the $W_k(k+1, k+3)$ model with the number of parafermionic primary fields (which should be equinumerous). The number of orbits is given by (e.g., [18] eq. (16.159)):

\[
\left\lfloor \frac{|P^3_+|}{k} \right\rfloor = \left\lfloor \frac{(k+2)!}{k! 3!} \right\rfloor = \left\lfloor \frac{(k+2)(k+1)}{6} \right\rfloor,
\] (46)

(where $\lfloor x \rfloor$ stands for the smallest integer larger than $x$). Inspection of the field identifications (17b) and (17c) (recalling that (17a) is a special case of (17c)) indicates that the bounds on $s$ and $t$ that generate an independent set of fields are

\[
0 \leq s \leq \left\lfloor \frac{k}{3} \right\rfloor, \quad 0 \leq t \leq k - 1 - 3s + \delta_{s, k/3}.
\] (47)

Counting the number of allowed solutions to these inequalities (treating the three cases $k = 3\ell + \epsilon$, with $\epsilon = 0, 1, 2$, separately) gives precisely the number (46).

This analysis makes the equivalence (4) firmly established.

ACKNOWLEDGMENTS

This work is supported by NSERC. I thank P. Jacob for his collaboration on [4] and V. Gurarie for discussions concerning [9].
