DEL PEZZO SURFACES WITH INFINITE AUTOMORPHISM GROUPS

IVAN CHELTSOV AND YURI PROKHOROV

ABSTRACT. We classify del Pezzo surfaces with Du Val singularities that have infinite automorphism groups, and describe the connected components of their automorphisms groups.

Throughout this paper, we always assume that all varieties are projective and defined over an algebraically closed field \( k \) of characteristic 0.

1. Introduction

Automorphism groups of smooth del Pezzo surfaces are well-studied (see, for example, [11, 12]). In particular, if \( X \) is a smooth del Pezzo surface, then \( \text{Aut}(X) \) is infinite if and only if \( X \) is toric. Moreover, if \( X \) is a smooth toric del Pezzo surface, then \( \text{Aut}^0(X) \) can be described as follows:

| \( K_X^2 \) | \( \text{Aut}^0(X) \) | equation & total space |
|---|---|---|
| 6 | \( G_m^2 \) | \( u_0v_0w_0 = u_1v_1w_1 \) | \( \mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1 \) |
| 7 | \( B_2 \times B_2 \) | | |
| 8 | \( G_a^2 \times \text{PGL}_2(k) \) | \( u_0v_0 = u_1v_1 \) | \( \mathbb{P}^2 \times \mathbb{P}^1 \) |
| 8 | \( \text{PGL}_2(k) \times \text{PGL}_2(k) \) | — | \( \mathbb{P}^1 \times \mathbb{P}^1 \) |
| 9 | \( \text{PGL}_2(k) \) | — | \( \mathbb{P}^2 \) |

where \( G_a \) is a one-dimensional unipotent additive group, \( G_m \) is a one-dimensional algebraic torus, and \( B_2 \) is the Borel subgroup of \( \text{PGL}_2(k) \). In this paper, we prove similar result for del Pezzo surfaces with at worst Du Val singularities. For short, we call such surfaces Du Val del Pezzo surfaces. Our main result is the following.

Main Theorem. Let \( X \) be a Du Val del Pezzo surface. Then the group \( \text{Aut}(X) \) is infinite if and only if \( X \) is described in Big Table in Section 8.

Everywhere below the number \( n^0 \) refers to the corresponding surface in Big Table in Section 8. As a consequence of our classification we have the following

Corollary 1.1. Let \( X \) be a Du Val del Pezzo surface. Then the group \( \text{Aut}(X) \) is not reductive if and only if \( X \) is one of the 23 surfaces \( 7^o, 14^o, 15^o, 18^o, 24^o, 25^o, 26^o, 27^o, 28^o, 31^o, 36^o, 37^o, 38^o, 39^o, 42^o, 43^o, 44^o, 45^o, 46^o, 48^o, 49^o, 50^o, 51^o \).

Thus, the surfaces listed in this corollary are not \( K \)-polystable [1, 22], which is known (see [25]).

Corollary 1.2. Let \( X \) be a Du Val del Pezzo surface.

(i) If \( K_X^2 = 1 \) and \( \text{Aut}(X) \) is infinite, then \( \rho(X) = 1 \).

(ii) If \( K_X^2 > 1 \) and \( \rho(X) = 1 \), then \( \text{Aut}(X) \) is infinite.

(iii) If \( K_X^2 \geq 6 \) or \( K_X^2 = 5 \) and \( X \) is singular, then \( \text{Aut}(X) \) is infinite.

Many particular parts of our classification have been previously studied from different perspectives. For examples, the Du Val del Pezzo surfaces admitting an effective action of the group \( G_a^2 \) and have been classified in [9]. The classification of toric Du Val del Pezzo surfaces is well-known for specialists (see e.g. [26]). Du Val del Pezzo surfaces that admit a faithful action of the group
Gm have been studied in [2, 16, 17] in terms of their Cox rings. Moreover, when we were finishing the final version of this paper, we were informed that Main Theorem has been independently proven in [21] using completely different approach, which also works in positive characteristic.

Note that the complete classification of all Du Val del Pezzo surfaces have been known for a long time [13, 11]. The basic problem is that its is very huge and to choose surfaces with infinite automorphism group typically takes a lot of efforts.

**Remark 1.3.** Almost all surfaces in Big Table are explicitly given by their defining equations, since they are not always uniquely determined by their degree and singularities. For example, the cubic surface in P3 given by

\[ x_3x_0^2 + x_1^3 + x_2^3 + x_0x_1x_2 = 0 \]

has one singular point of type D4, its automorphism group is finite, and it is not isomorphic to the cubic surface \[220] which has the same singularity. Similarly, the quartic surface in the weighted projective space \( \mathbb{P}(1,1,1,2) \) that is given by the equation

\[ y_2^2 = y_1^3y'' + y_1^4 + y_1^2y_1^2 \]

is a del Pezzo surface of degree 2 that has one singular point of type E6. It is not isomorphic to the del Pezzo surface \[110\] which has the same degree and the same singularity. There are more examples like this: the surface \[10\] and the sextic surface in \( \mathbb{P}(1,1,2,3) \) given by

\[ y_3^2 = y_2^3 + y_1^5 + y_2^2y_1^2 \]

are the only del Pezzo surfaces of degree 1 with singular point of type E8. They are not isomorphic. In fact, the latter surface is the only Du Val del Pezzo surface whose class group is \( \mathbb{Z} \) that does not appear in our Big Table (see Remark B.5).

Let us briefly describe the structure of this paper. In Section 2, we present several basic facts about Du Val del Pezzo surfaces which are used in the proof of Main Theorem. In Section 3, we prove Theorem 3.8, which together with Main Theorem imply

**Corollary 1.4.** Let \( X \) be a Du Val del Pezzo surface with \( K_X^2 \geq 3 \), and let \( \tau(X) \) be its Fano–Weil index. Suppose that \( \tau(X) > 1 \). Then \( \text{Aut}(X) \) is infinite.

In Section 4, we prove Main Theorem for del Pezzo surfaces of degree \( \geq 4 \). Then, in Sections 5, 6, 7, we prove Main Theorem for del Pezzo surfaces of degree 1, 2, 3, respectively. In Section 8, we present Big Table. In Appendix A, we describe lines on del Pezzo surfaces that appear in Big Table together with the dual graphs of the curves with negative self-intersection numbers on their minimal resolutions. Finally, in Appendix B, we will recall classification of Du Val del Pezzo surfaces whose Weil divisor class group is cyclic, and present an alternative proof of Main Theorem for them.

**Notations.** Throughout this paper, we will use the following notation:

- \( \mu_n \) is a cyclic subgroup of order \( n \).
- \( G_a \) is a one-dimensional unipotent additive group.
- \( G_m \) is a one-dimensional algebraic torus.
- \( B_n \) is a Borel subgroup of \( \text{PGL}_n(k) \).
- \( U_n \) is a maximal unipotent subgroup of \( \text{PGL}_n(k) \).
- \( G_a \rtimes G_m \) is a semidirect product \( G_a \) and \( G_m \) such that \( G_m \) acts on \( G_a \) as \( x \mapsto t^ax \). This group is isomorphic to the following group:

\[ \left\{ \begin{pmatrix} 1 & 0 & 0 \\ 0 & t^r & 0 \\ 0 & a & t^s \end{pmatrix} \in \text{GL}_3(k) \mid t \in k^* \text{ and } a \in k \right\}, \]
where \( s = r \pm n \). Observe that \( \mathbb{G}_a \times (0) \mathbb{G}_m = \mathbb{G}_a \times \mathbb{G}_m, \mathbb{G}_a \times (1) \mathbb{G}_m = \mathbb{B}_2 \) and
\[
\mathbb{G}_a \times (n) \mathbb{G}_m \cong \mathbb{G}_a \times (-n) \mathbb{G}_m.
\]

Therefore, we will always assume that \( n \geq 0 \). If \( n > 0 \), the center of \( \mathbb{G}_a \times (n) \mathbb{G}_m = \mathbb{G}_a \times (n) \mathbb{G}_m \), \( \mathbb{G}_a \times (1) \mathbb{G}_m = B_2 \) and \( \mathbb{G}_a \times (n) \mathbb{G}_m \sim \mathbb{G}_a \times (-n) \mathbb{G}_m \iff n_1 = \pm n_2 \).

- \( F_n \) is the Hirzebruch surface.
- \( \mathbb{P}(a_0, a_1, \ldots, a_n) \) is the weighted projective space.
- For a weighted projective space \( \mathbb{P}(a_0, a_1, \ldots, a_n) \), we denote by \( y_{a_0}, y_{a_1}, \ldots, y_{a_n} \) the coordinates on it of weights \( a_0, a_1, \ldots, a_n \), respectively.
- For a variety \( X \), we denote by \( \operatorname{Sing}(X) \) the set of its singular points.
- For a variety \( X \), we denote by \( \rho(X) \) the rank of the Weil divisor class group \( \operatorname{Cl}(X) \).
- For a variety \( X \) and its (possibly reducible) reduced subvariety \( Y \subseteq X \), \( \operatorname{Aut}(X, Y) \) denotes the group consisting of all automorphisms in in \( \operatorname{Aut}(X) \) that maps \( Y \) into itself.
- For a Du Val del Pezzo surface \( X \), \( \tau(X) \) denotes its Fano–Weil index, which is defined as follows:
\[
\tau(X) = \max \left\{ t \in \mathbb{Z} \mid -K_X \sim tA, \text{ where } A \text{ is a Weil divisor on } X \right\}.
\]

## 2. Del Pezzo surfaces with Du Val singularities

Let \( X \) be a Du Val del Pezzo surface with \( d := K_X^2 \). Then \( d \) is known as the degree of the surface \( X \). Let \( \mu : \widetilde{X} \to X \) be the minimal resolution of singularities. Then
\[
K_{\widetilde{X}} \sim \mu^*K_X,
\]
so that \( \widetilde{X} \) is a *weak del Pezzo surface*, that is, the anticanonical divisor \(-K_{\widetilde{X}}\) is nef and big. By the Noether formula \( d = 10 - \rho(X) \leq 9 \) and by the genus formula every irreducible curve on \( \widetilde{X} \) with negative self-intersection number is either \((-1)\)- or \((-2)\)-curve. Moreover, one of the following holds (see [4, 18]):

1. \( K_{\widetilde{X}}^2 = 9 \) and \( \widetilde{X} \cong X \cong \mathbb{P}^2 \);
2. \( K_{\widetilde{X}}^2 = 8 \) and \( \widetilde{X} \cong X \cong \mathbb{F}_1 \);
3. \( K_{\widetilde{X}}^2 = 8 \) and \( \widetilde{X} \cong X \cong \mathbb{P}^1 \times \mathbb{P}^1 \);
4. \( K_{\widetilde{X}}^2 = 8, \widetilde{X} \cong \mathbb{F}_2 \) and \( X \) is a quadric cone in \( \mathbb{P}^3 \);
5. \( K_{\widetilde{X}}^2 \leq 7 \) and there exists a \( \operatorname{Aut}^0(X) \)-equivariant diagram

\[
\begin{array}{ccc}
\mathbb{P}^2 & \xrightarrow{\varphi} & \widetilde{X} \\
\downarrow & & \downarrow \mu \\
& \xleftarrow{} & X.
\end{array}
\]

where \( \varphi \) is a suitable contraction of \((-1)\)-curves.

Moreover, it follows from the Kawamata–Viehweg vanishing and the exponential exact sequence that the group \( \operatorname{Pic}(X) \) is torsion free.
Corollary 2.2. Let $G$ be a connected algebraic subgroup in $\text{Aut}(X)$. Suppose that $d = K_X^2 \leq 7$. Then $G$ is isomorphic to a subgroup of the following group:
\[
\left\{ \begin{pmatrix} a_{11} & 0 & 0 \\ a_{21} & a_{22} & 0 \\ a_{31} & a_{32} & 1 \end{pmatrix} \in \text{GL}_3(k) \mid a_{ij} \in k, a_{11} \neq 0, a_{22} \neq 0 \right\} \cong \mathbb{U}_3 \times \mathbb{G}_m.
\]
In particular, the group $G$ is solvable. If $G$ is reductive and non-trivial, then $G \cong \mathbb{G}_m$ or $G \cong \mathbb{G}_m^2$. Similarly, if $G$ is unipotent, then $G \cong \mathbb{G}_a$ or $G \cong \mathbb{G}_a^2$ or $G \cong \mathbb{U}_3$.

Proof. This follows from the fact that the diagram (2.1) is $G$-equivariant. \hfill \square

Example 2.3 ([7 Proposition 8.1]). Suppose that $d = 7$ and $X$ is singular. The surface $X$ is unique. The morphism $\varphi$ is the blow up of two points, $\tilde{X}$ contains unique $(-2)$-curve, and $\text{Type}(X) = A_1$. The surface $X$ contains two $(-1)$-curves. The dual graph of curves with negative self-intersection numbers has the form
\[
\circ \quad - \quad \bullet
\]
where $\bullet$ denotes a $(-1)$-curve, and $\circ$ denotes the $(-2)$-curve. Using (2.1), we see that
\[
\text{Aut}^0(X) \cong \text{Aut}(\mathbb{P}^2, \ell, P) \cong \mathbb{P}_3,
\]
where $\ell$ is a line on $\mathbb{P}^2$, and $P$ is a point in $\ell$. Note that $X$ is the surface $48^9$.

The type $\text{Type}(X)$ does not always determine the dual graph of curves with negative self-intersection numbers in $\tilde{X}$. However, this graph is always determined by the type $\text{Type}(X)$ and the number of $(-1)$-curves in $\tilde{X}$. In the following, we denote by $\#(X)$ the number of $(-1)$-curves in the surface $\tilde{X}$.

Example 2.4. If $d = 6$ and $\text{Type}(X) = A_1$, then $X$ is one of the surfaces $45^9$ or $46^9$ in Big Table. If $X$ is the surface $45^9$, then $\#(X) = 3$. On the other hand, if $X$ is the surface $46^9$, then $\#(X) = 4$. The dual graph of curves with negative self-intersection numbers in $\tilde{X}$ is given in Appendix A.

Using the Riemann–Roch formula and Kawamata–Viehweg vanishing, we get $\dim | - K_X | = d$. Let $\Phi : X \dasharrow \mathbb{P}^d$ be the rational map given by $| - K_X |$. The linear system $| - K_X |$ does not have fixed components, and it contains a smooth elliptic curve (see [8]). Using this fact, one can prove

Theorem 2.5 ([8 [18]). The following assertions hold:

(i) if $d \geq 2$, then $| - K_X |$ is base point free, so that $\Phi$ is a morphism;
(ii) if $d \geq 3$, then $-K_X$ is very ample, so that $\Phi$ is an embedding;
(iii) if $d = 3$, then $\Phi(X)$ is a cubic surface in $\mathbb{P}^3$;
(iv) if $d \geq 4$, then $\Phi(X)$ is an intersection of quadrics in $\mathbb{P}^d$;
(v) if $d = 2$, then $\Phi$ is a double cover that is branched over a possibly reducible quartic curve, so that $X$ is a hypersurface in $\mathbb{P}(1,1,1,2)$ of degree 4;
(vi) if $d = 1$, then $| - K_X |$ is an elliptic pencil, its base locus consists of one point $O \notin \text{Sing}(X)$, and every curve in $| - K_X |$ is irreducible and smooth at $O$;
(vii) if $d = 1$, then $| - 2K_X |$ defines a double cover $X \rightarrow \mathbb{P}(1,1,2)$ branched over a sextic curve, so that $X$ is a hypersurface in $\mathbb{P}(1,1,2,3)$ of degree 6.

The number of $(-1)$-curves in $\tilde{X}$ is finite.

Definition 2.6. An irreducible curve $L \subset X$ is a line if $L = \mu(\tilde{L})$ for a $(-1)$-curve $\tilde{L} \subset \tilde{X}$.

If $d \geq 3$, then lines in $X$ are usual (projective) lines in $\Phi(X) \subset \mathbb{P}^d$. Conversely, if $d \geq 3$, then lines in $\Phi(X)$ are lines in the sense of Definition 2.6. Moreover, if $d = 2$, then lines in $X$ are smooth rational curve. Furthermore, if $d = 1$ and $L$ is a line in $X$, then
• either \( L \) is singular curve in \( |-K_X| \) such that \( \text{Sing}(L) \subset \text{Sing}(X) \),
• or \( L \) is a smooth rational curve that does not contain the base point of the pencil \( |-K_X| \).

Note that \( #(X) \) is the number of lines in \( X \). Then \( #(X) > 0 \) unless \( X \) is \( \mathbb{P}^2 \), \( \mathbb{P}^1 \times \mathbb{P}^1 \) or \( \mathbb{P}(1,1,2) \).

**Lemma 2.7.** Assume that \( d \geq 3 \). Let \( P \) be a point in \( X \), and let \( #(X,P) \) be the number of lines in \( X \) passing through \( P \).

(i) If \( P \in X \) is smooth, then

\[
#(X,P) \leq \begin{cases} 
3 & \text{if } d = 3, \\
2 & \text{if } d \geq 4.
\end{cases}
\]

(ii) If \( P \in X \) is singular, then

\[
#(X,P) \leq \begin{cases} 
6 & \text{if } d = 3, \\
4 & \text{if } d = 4, \\
3 & \text{if } d \geq 5.
\end{cases}
\]

**Proof.** Let us prove the required assertion only in one case. The proofs in other cases are similar. Namely, suppose that \( d = 5 \) and \( P \in \text{Sing}(X) \). Let us show that \( r \leq 3 \). To do this, we suppose that \( r \geq 4 \). Let us seek for a contradiction.

Let \( L_1, L_2, L_3 \) and \( L_4 \) be distinct lines on \( X \) that contain \( P \), and let \( Q \) be a point in \( X \) that is not contained in any line in \( X \) (such point exists since \( #(X) \) is finite). Keeping in mind that the Zariski tangent space of the surface \( X \) at the point \( P \) is three-dimensional, we conclude that there exists a hyperplane \( H \) in \( \mathbb{P}^5 \) that contains the lines \( L_1, L_2, L_3, L_4 \) and the point \( Q \). Then

\[
H \mid_X = C + \sum_{i=1}^{4} L_i,
\]

where \( C \) is a curve in \( X \) that passes through \( Q \). Counting degrees, we see that \( \deg(C) \leq 1 \), so that \( C \) is a line, which contradicts the choice of the point \( Q \). \( \square \)

**Lemma 2.8.** Suppose that \( d \leq 7 \). For any singular point of \( X \) there is a line passing through it.

**Proof.** The required assertion follows from the existence of the diagram (2.1). \( \square \)

Since the Du Val singularities are \( \mathbb{Q} \)-factorial, \( \rho(X) \) is equal to the rank of the Weil divisor class group \( \text{Cl}(X) \).

**Lemma 2.9.** Suppose that \( d \leq 7 \). Then the following assertions hold.

(i) The group \( \text{Cl}(X) \) is generated by the classes of lines in \( X \).

(ii) Let \( \text{Cl}(X)_{\text{tors}} \subset \text{Cl}(X) \) be the torsion subgroup and let \( n \) be the order of the group \( \text{Cl}(X)_{\text{tors}} \). There is a Galois abelian cover \( \pi: Y \to X \) of degree \( n \) which is étale outside of \( \text{Sing}(X) \), where \( Y \) is a Du Val del Pezzo surface such that

\[
K_Y^2 = dn,
\]

so that \( n \leq \frac{9}{4} \).

(iii) If \( \rho(X) = 1 \) and \( X \) contains two distinct lines \( L \) and \( L' \), then \( L \not\sim L' \) and \( L \sim_\mathbb{Q} L' \).

(iv) Every extremal ray of the Mori cone \( \overline{\text{NE}}(X) \) is generated by the class of a line.

(v) For every effective divisor \( D \in \text{Cl}(X) \), there are \( a_0, a_1, \ldots, a_r \in \mathbb{Z}_{\geq 0} \) such that

\[
D \sim a_0(-K_X) + \sum_{i=1}^{r} a_i L_i,
\]

where \( L_1, \ldots, L_r \) are lines in \( X \), \( r = #(X) \), and \( a_0 = 0 \) if \( d \neq 1 \).
Proof. We will prove only assertion (v). Let \( \widetilde{D} \) be the proper transform on \( \widetilde{X} \) of the divisor \( D \). To prove (v) it is sufficient to show that the divisor \( \widetilde{D} \) is rationally equivalent to a convex integral linear combination of \((-1)\) and \((-2)\)-curves (and \(-K_{\widetilde{X}}\) if \( d = 1 \)).

We may assume that \( D \) is an irreducible curve.

Let us use induction on \( \dim |D| \). If \( \dim |D| = 0 \), then \( \widetilde{D} \) is either a \((-1)\) or \((-2)\)-curve by the Riemann-Roch formula and Kawamata-Viehweg vanishing. This is the base of induction.

Suppose that \( \dim |D| \geq 1 \) and the required assertion holds for any effective divisor \( \widetilde{D}' \) on \( \widetilde{X} \) such that \( \dim |\widetilde{D}'| < \dim |D| \). Observe that \( \widetilde{D} \) is nef. Thus, if \( \widetilde{D}^2 = 0 \), then \( |\widetilde{D}| \) is base point free and gives a conic bundle \( \widetilde{X} \to \mathbb{P}^1 \), which must have at least one reducible fiber, because \( \rho(\widetilde{X}) \geq 3 \). Hence, if \( \widetilde{D}^2 = 0 \), then we can proceed by induction. Thus, we may assume that \( \widetilde{D}^2 \geq 1 \).

If \( \widetilde{D} \) is not ample, then \( \widetilde{X} \) contains an irreducible curve \( \tilde{C} \) such that \( \widetilde{D} \cdot \tilde{C} = 0 \), which implies that \( \tilde{C}^2 < 0 \) by the Hodge index theorem, so that \( \tilde{C}^2 = -1 \) or \( \tilde{C}^2 = -2 \), which gives

\[
\dim |\widetilde{D} - \tilde{C}| \geq \dim |\widetilde{D}| - 1 \geq 0.
\]

Hence, if \( \widetilde{D} \) is not ample, then there exists an effective divisor \( \widetilde{D}' \) such that \( \widetilde{D} \sim \widetilde{D}' + \tilde{C} \), so that we can proceed by induction. Therefore, we may assume that \( \widetilde{D} \) is ample.

Suppose that \( \widetilde{D} \sim -K_{\widetilde{X}} \) and \( K_{\widetilde{X}}^2 \geq 2 \). Then for any \((-1)\)-curve \( \tilde{C} \) on \( \widetilde{X} \) we have

\[
\dim |\widetilde{D} - \tilde{C}| \geq \dim |\widetilde{D}| - 2 \geq 0,
\]

so that there is an effective divisor \( \widetilde{D}' \) such that \( \widetilde{D} \sim \widetilde{D}' + \tilde{C} \), and we can proceed by induction.

Finally, we assume that \( \widetilde{D} \) is ample and \( \widetilde{D} \not\sim -K_{\widetilde{X}} \). There is a \( n \in \mathbb{N} \) such that \( \widetilde{D} + aK_{\widetilde{X}} \) is nef but not ample, because the Mori cone of the surface \( \widetilde{X} \) is generated by \((-1)\)-curves and \((-2)\)-curves. Now using the Riemann-Roch formula and Kawamata–Viehweg vanishing, we see that the linear system \( |\widetilde{D} + aK_{\widetilde{X}}| \) contains a divisor \( \widetilde{D}' \), so that

\[
\widetilde{D} \sim \widetilde{D}' - aK_{\widetilde{X}},
\]

where \( \widetilde{D}' \) and \(-K_{\widetilde{X}}\) are both decomposable in the required form. \( \square \)

Corollary 2.10. One has \#(X) \geq \rho(X). Moreover, if \#(X) = \rho(X), then Cl(X) is torsion free, and every line in X generates an extremal ray of the Mori cone \( \text{NE}(X) \).

Corollary 2.11. Suppose that \( d \leq 7 \), and \( X \) admits a faithful \( \mathbb{G}^2_a \) action. Then \#(X) = \rho(X). Moreover, the complement to the open orbit coincides with the union of lines.

Proof. Let \( U \) be the open \( \mathbb{G}^2_a \) orbit, let \( \widetilde{U} = \mu^{-1}(U) \), let \( \overline{U} = \varphi(\widetilde{U}) \), let \( B = X \setminus U \), let \( \overline{B} = \widetilde{X} \setminus \overline{U} \), and let \( B' = \mathbb{P}^2 \setminus \overline{U} \). Then

\[
U \cong \widetilde{U} \cong \overline{U} \cong \mathbb{A}^2,
\]

so that the curve \( \overline{B} \) must be a line. Then \( \overline{B} \) has \( \rho(\widetilde{X}) \) components, and \( B \) has \( \rho(X) \) components. Since all \((-1)\)-curves on \( \widetilde{X} \) are contained in \( \overline{B} \), we see that all the lines in \( X \) are contained in \( \overline{B} \). This gives \#(X) \leq \rho(X). But \#(X) \geq \rho(X) by Corollary 2.10. \( \square \)

Observe that a line \( L \) on the surface \( X \) generates an extremal ray of \( \text{NE}(X) \) \iff \( L^2 \leq 0 \).

Lemma 2.12 (Proposition 1.2, [27 § 7.1]). Let \( V \) be a surface that has Du Val singularities, and let \( \psi : V \to Y \) be an extremal Mori contraction. Then one of the following holds:

(i) either \( \psi \) is a weighted blow up of a smooth point in \( Y \) with weights \((1, n)\), the exceptional curve \( E \) is smooth and rational, one has \( E^2 = -\frac{1}{n} \), and \( E \cap \text{Sing}(V) \) consists of one point which is of type \( A_{n-1} \) on \( V \);
Corollary 2.14. Suppose there exists a birational morphism \( E \) and let \( \psi \) be the exceptional curve of the morphism \( E \). Then 2
\[ \psi(X) : \psi(Y) = \psi(X) - 1; \]
the point \( \psi(E) \) is a smooth point of the surface \( Y \);
\[ Y \text{ is a Du Val del Pezzo surface, } K_Y^2 = d + n \text{ and } \rho(Y) = \rho(X) - 1; \]
the point \( \psi(E) \) is not contained in a line in \( Y \).

Corollary 2.15. Let \( \psi : X \to Y \) be a contraction of a proper face of the cone \( \overline{NE}(X) \). Then
\[ \text{either the morphism } \psi \text{ is birational, } Y \text{ is a Du Val del Pezzo surface, and } \psi \text{ contracts a disjoint union of lines on the surface } X, \]
or the morphism \( \psi \) is a conic bundle and \( Y \simeq \mathbb{P}^1 \).

If a del Pezzo surface \( X \) is smooth and \( \rho(X) \geq 2 \), then \( X \) always admits a conic bundle contraction. However, this is not always the case if \( X \) has Du Val singularities.

Lemma 2.16. Let \( X \) be a Du Val del Pezzo surface of degree \( d \) with \( \rho(X) \geq 2 \).
(i) Assume that \( d = 3 \). Then there exists a conic bundle structure \( \psi : X \to \mathbb{P}^1 \) if and only if \( X \) contains a line \( L \) that is contained in \( X \setminus \text{Sing}(X) \).
(ii) Assume that \( d = 4 \). Then there exists a conic bundle structure \( \psi : X \to \mathbb{P}^1 \) if and only if there is a double cover \( \pi : X \to \mathbb{P}^1 \times \mathbb{P}^1 \) branched over a curve of degree \( (2, 2) \).

Proof. If \( d = 3 \), then \( X \) is a cubic surface in \( \mathbb{P}^3 \), so that every conic bundle \( \psi : X \to \mathbb{P}^1 \) is given by the linear projection from some line in \( X \) that does not contain singular points of the surface \( X \), so that \( X \) admits a conic bundle contraction if and only if such a line exists.
Assume that \( d = 4 \). If there is a double cover \( X \to \mathbb{P}^1 \times \mathbb{P}^1 \) branched over a curve of degree \( (2, 2) \), then composing it with a projection to one of the factors, we obtain the required conic bundle. Thus, we may assume that there exists a conic bundle \( \psi : X \to \mathbb{P}^1 \). Let \( C \) be its general fiber. Then \( | - K_X - C | \) is base point free and gives another conic bundle \( \psi' : X \to \mathbb{P}^1 \). Let \( \pi = \psi \times \psi' \). Then \( \pi : X \to \mathbb{P}^1 \times \mathbb{P}^1 \) is the required double cover.

3. The Fano–Weil index of Du Val del Pezzo surfaces

Recall from Section 1 that \( \tau(X) \) is the Fano–Weil index of a del Pezzo surface \( X \).

Lemma 3.1. Let \( X \) be a Du Val del Pezzo surface with \( \rho(X) = 1 \). Then \( \tau(X) = K_X^2 \).

Proof. Let \( d := K_X^2 \) and \( D := K_X + dL \), where \( L \) is a line on \( X \). If \( D \sim 0 \), then we are done. Suppose that \( D \not\sim 0 \). Since \( D \sim 0 \), the divisor \( D \) is a non-trivial torsion in \( \text{Cl}(X) \). Let \( n \) be its order. Then \( 2 \leq n \leq \frac{2}{d} \) by Lemma 2.9 so that either \( d = 3 \) or \( d = 4 \).

Suppose that \( d = 4 \). Then either \( \text{Type}(X) = A_32A_1 \) or \( \text{Type}(X) = D_5 \) by [7, Proposition 6.1]. In the former case, we see that \( 4L \) is a Cartier divisor, so that \( D \sim 0 \), since \( \text{Pic}(X) \) is torsion free. In the latter case, \( L \) is the unique line in \( X \) by [7, Proposition 6.1], so that \( D \sim 0 \) by Lemma 2.9.
Thus, in both cases we obtain a contradiction with our assumption that \( D \not\sim 0 \).
Thus, we see that $d = 3$. Then either $n = 2$ or $n = 3$. If $n = 2$, we have
\[ K_X + 3(L + D) \sim 4K_X + 12L \sim 4(K_X + 3D) \sim 0, \]
so that $\tau(X) = 3$. If $n = 3$, then $X \cong \mathbb{P}^2/\mu_3$ by Lemma 2.9, which implies that Type($X$) = 3A$_2$. In this case, the divisor $3L$ is Cartier, which gives $D \sim 0$, because Pic($X$) is torsion free. \hfill \square

The number $\tau(X)$ divides the degree $d$ of the del Pezzo surface $X$, so that $\tau(X) = 1$ if $d = 1$. If $d \geq 2$, then the Fano–Weil index $\tau(X)$ is closely related to the following notion:

**Definition 3.2.** A del Pezzo surface $X$ is said to be weakly minimal if $X$ does not contain lines that are contained in the smooth locus of the surface $X$.

**Remark 3.3.** If $X$ is a weakly minimal Du Val del Pezzo surface, and $\psi : X \to Y$ is a birational contraction, then $Y$ is a weakly minimal Du Val del Pezzo surface by Corollary 2.14.

Now, we prove the following result.

**Proposition 3.4.** Let $X$ be a Du Val del Pezzo surface and let $d := K^2_X$.

(i) If $\tau(X) = d$, then $d \leq 6$ and $X$ is a hypersurface in $\mathbb{P}(1, 2, 3, d)$ of degree 6 given by
\[ y_2^3 + y_1 y_3^2 + \lambda_1 y_1 y_2 + \lambda_2 y_1^6 + y_d \phi(y_1, y_2, y_d) = 0, \]
where $\phi$ is a polynomial of degree $6 - d$, and $\lambda_1$ and $\lambda_2 \in \mathbb{k}$ such that $4\lambda_1^3 + 27\lambda_2^2 \neq 0$.

(ii) If $\tau(X) = \frac{d}{2}$, then $X$ is a hypersurface in $\mathbb{P}(1, 1, 2, \frac{d}{2})$ of degree 4 given by
\[ y_2^2 + y_1 y_1(y_1 - y_0)(y_1 - \lambda y_0) + x_3 \phi(y_1, y_1, x_3) = 0, \]
where $\phi$ is a polynomial of degree $4 - \frac{d}{2}$, and $\lambda \in \mathbb{k}$ such that $\lambda \neq 0$ and $\lambda \neq 1$.

(iii) If $d = 6$ and $\tau(X) = 2$, then $X$ is a hypersurface in $\mathbb{P}(1, 1, 1, 2)$ of degree 3 given by
\[ \psi(y_1, y_1', y_1'') + y_2 \phi(y_1, y_1', y_1'') = 0, \]
where $\psi$ and $\phi$ are polynomials of degree 3 and 1, respectively.

**Proof.** Let us only prove the assertion (i), since the assertions (ii) and (iii) can be proved similarly. Let $C$ be a general curve in $| - K_X |$. Then $C$ is a smooth elliptic curve (see, for example, [8]). Suppose that $\tau(X) = d$. Then $-K_X \sim dA$, where $A$ is a Weil divisor on $X$. Consider the natural homomorphism of graded algebras
\[ \Phi : R(X, A) := \bigoplus_{n \geq 0} H^0(X, \mathcal{O}_X(nA)) \longrightarrow \bigoplus_{n \geq 0} H^0(C, \mathcal{O}_C(nA)) =: R(C, A) \]
By the Kawamata–Viehweg vanishing it is surjective. Note that $\mathcal{O}_C(A)$ is a line bundle of degree 1. It is well-known that $R(C, A)$ is generated by 3 elements $\bar{y}_1, \bar{y}_2, \bar{y}_3$ with deg $\bar{y}_i = i$ such that
\[ \bar{y}_3^2 + \bar{y}_2^2 + \lambda_1 \bar{y}_1^4 \bar{y}_2 + \lambda_2 \bar{y}_1^6 = 0 \]
for some $\lambda_1$ and $\lambda_2$ in $\mathbb{k}$ such that $4\lambda_1^3 + 27\lambda_2^2 \neq 0$. The kernel of $\Phi$ is generated by a homogeneous element $y_d$ of degree $d$. Take arbitrary elements $y_1, y_2$ and $y_3$ in $R(X, A)$ such that $\Phi(y_i) = \bar{y}_i$. Then $R(X, A)$ is generated by $y_1, y_2, y_3$ and $y_d$. This gives us an embedding
\[ X \cong \text{Proj} \left( R(X, A) \right) \hookrightarrow \text{Proj} \left( \mathbb{k}[y_1, y_2, y_3, y_d] \right) \cong \mathbb{P}(1, 2, 3, d) \]
whose image is given by an equation of the required form. \hfill \square

**Remark 3.5.** The embedding of the surface $X$ described in Proposition 3.4 is almost canonical. It only depends on the choice of the divisor class $A \in \text{Cl}(X)$ such that $-K_X \sim \tau(X)A$, which is uniquely defined modulo $\tau(X)$-torsion. Thus, this embedding is Aut$^0(X)$-equivariant.

Using Theorem 3.12 and Proposition 3.4, we can describe many del Pezzo surfaces:
Example 3.6. Suppose that $d = 3$, $\tau(X) = 3$, and $\text{Type}(X) = 2A_2$. Using Proposition 3.4, we see that $X$ is a hypersurface in $\mathbb{P}(1,2,3,3)$ of degree 3 that is given by
\[y_3y'_3 = y_2(y_2 - y'_1^2)(y_2 - \lambda y_1^2),\]
where $\lambda \in k \setminus \{0, 1\}$.

Example 3.7. Suppose that $d = 4$, $\tau(X) = 3$, and $\text{Type}(X) = 2A_1$. Using Proposition 3.4, we see that $X$ is a hypersurface in $\mathbb{P}(1,1,2,2)$ of degree 4 that is given by
\[y_2y'_2 = y_1(y'_1 - y_1)(y'_1 - \lambda y_1),\]
where $\lambda \in k \setminus \{0, 1\}$. This surface is known as the Iskovskikh surface (see [20]).

Similarly, we can use Proposition 3.4 to prove the following result:

**Theorem 3.8.** Let $X$ be a Du Val del Pezzo surface and let $d := K_X^2$. Suppose that $X$ is singular, $d \geq 3$ and $\tau(X) > 1$. Then $X$ is a hypersurface in a weighted projective space $\mathbb{P}$ such that one of the following possibilities holds:

| $\mathbb{N}$ | $d$ | $\rho$ | Type | $\tau$ | $\mathbb{P}$ | equation of $X$ |
|-------------|-----|--------|------|--------|-------------|-----------------|
| 23\(\bigcirc\) | 3   | 3      | 2A2  | 3      | $\mathbb{P}(1,2,3,3)$ | see Example 3.6 |

| 45\(\bigcirc\) | 3   | 1      | A1   | 2      | $\mathbb{P}(1,1,1,2)$ | $y'_1^2y_2 = y_1(y_1 - y'_1)$ |
| 41\(\bigcirc\) | 2   | 2      | A1   | 2      | $\mathbb{P}(1,1,1,2)$ | $y'_1^2y_2 = y_1^2y'_1$ |
| 43\(\bigcirc\) | 2   | 2      | A2   | 3      | $\mathbb{P}(1,1,2,3)$ | $y_1y_5 = y_2^2 - y'_1^4$ |
| 50\(\bigcirc\) | 8   | 1      | A1   | 4      | $\mathbb{P}(1,1,2)$ | — |
Proof. The required assertion follows from Proposition 3.4. Let us show this in the case $d = 3$. Suppose that $d = 3$ and $\tau(X) > 1$. By Proposition 3.4, $X$ is a surface in $\mathbb{P}(1, 2, 3, 3)$ given by

$$y_3^2 + y_1^3 + \lambda_1 y_1^4 y_2 + \lambda_2 y_1^6 + \lambda_3 x_1^2 + \lambda_4 x_1 y_1 y_2 + \lambda_5 x_3 y_1^3 = 0$$

for some $\lambda_1$, $\lambda_2$, $\lambda_3$, $\lambda_4$ and $\lambda_5$ in $\mathbb{k}$. If $\lambda_3 \neq 0$, then completing the square we reduce this equation to the defining equation of one the surfaces $16^o$, $21^o$ or $23^o$. Thus, we may assume that $\lambda_3 = 0$.

If $\lambda_4 \neq 0$, then we can use a coordinate change $x_3 \mapsto \alpha x_3 + \beta y_1^3$ and $y_2 \mapsto \gamma y_2 + \delta y_1^2$ for appropriate $\alpha$, $\beta$, $\gamma$ and $\delta$ in $\mathbb{k}$ to reduce our equation to

$$y_2^2 + y_3^2 + \lambda_2 y_1^6 + x_3 x_1 y_2 = 0.$$ 

If $\lambda_2 = 0$, this equation defines the surface $15^o$. On the other hand, if $\lambda_2 \neq 0$, we can scale the coordinates to get $\lambda_2 = 1$, so that we obtain the defining equation of the surface $18^o$.

We may assume that $\lambda_3 = \lambda_4 = 0$. If $\lambda_5 = 0$, then $X$ has a non-Du Val singularity at $(0 : 0 : 0 : 1)$, so that $\lambda_5 \neq 0$. Then we reduce our equation to the defining equation of the surface $14^o$. 

Remark 3.9. Using Theorem 3.8, we can easily obtain the anticanonical embedding of the surface $X \hookrightarrow \mathbb{P}^d$. For instance, if $d = 3$ and $\tau(X) = 3$, the map $\mathbb{P}(1, 2, 3, 3) \dashrightarrow \mathbb{P}^3$ given by

$$(y_1 : y_2 : y_3 : y_3') \mapsto (y_3^2 : y_1 y_2 : y_3 : y_3')$$

defines an embedding $X \hookrightarrow \mathbb{P}^3$, so that $X$ is a cubic in $\mathbb{P}^3$ given by

$$23^o x_0 x_2 x_3 = x_1 (x_1 - x_0) (x_1 - \lambda x_0), \text{ where } \lambda \in \mathbb{k} \setminus \{0, 1\};$$

$$21^o x_0 x_2 x_3 = x_1^3 + x_0 x_1^2;$$

$$16^o x_0 x_2 x_3 = x_1^3;$$

$$18^o x_0 x_3^2 = x_1^3 + x_0^3 + x_0 x_3 x_1;$$

$$15^o x_0 x_2^3 = x_1^3 + x_0 x_3 x_1;$$

$$14^o x_0 x_2^3 = x_1^3 + x_3 x_2^3. $$

If $X$ is not weakly minimal, then $\tau(X) = 1$. In particular, if the del Pezzo surface $X$ is smooth, then $\tau(X) = 1$ unless $X \cong \mathbb{P}^2$ or $X \cong \mathbb{P}^1 \times \mathbb{P}^1$. However, if $X$ is weakly minimal and $d \geq 2$, we cannot immediately conclude that $\tau(X) > 1$. Let us present two examples.

Example 3.10. Let $X$ be a quintic del Pezzo surface with $\rho(X) = 2$ admitting a conic bundle contraction $\psi_1 : X \rightarrow \mathbb{P}^1$. It is easy to see from Lemma 2.12 that $\text{Type}(X) = A_3$ and the second extremal contraction is a birational $(1, 4)$-contraction $\psi_2 : X \rightarrow \mathbb{P}^2$. Then $X$ is weakly-minimal.

We have a morphism $\psi = (\psi_1, \psi_2) : X \rightarrow \mathbb{P}^1 \times \mathbb{P}^2$ which is finite onto its image. In fact, one can show that $\psi$ is an $\text{Aut}(X)$-equivariant embedding. In suitable coordinates $(v_0 : v_1; u_0 : u_1 : u_2)$ the equation of the image is

$$u_2^2 v_0 + (u_0^2 + u_1 u_2) v_1 = 0,$$

so that $X$ is the surface $37^o$. Let $\tau = \tau(X)$, and let $A$ be a Weil divisor on $X$ such that $-K_X \sim \tau A$. Then $5 = K_X^2 \sim -\tau K_X \cdot A$ and $2 = -K_X \cdot C = \tau A \cdot C$, where $C$ is a general fiber $C$ of the conic bundle $\psi_1$. Since $K_X \cdot A$ and $A \cdot C$ are integers, we have $\tau = 1$.

Example 3.11. Let $X$ be a Du Val cubic surface in $\mathbb{P}^3$ with $\text{Type}(X) = A_4 A_1$. Then $\rho(X) = 2$, and it follows from $[6]$ that $X$ is unique up to isomorphism and can be given by the equation

$$x_0 x_2 x_3 + x_0^2 x_1 + x_1^2 x_3 = 0,$$

so that $X$ is the surface $19^o$. Observe that $X$ contains exactly four lines:

$$L_1 = \{x_0 = x_1 = 0\}, \quad L_2 = \{x_1 = x_3 = 0\}, \quad L_3 = \{x_1 = x_2 = 0\}, \quad L_4 = \{x_0 = x_3 = 0\}$$

and $-K_X \sim L_1 + L_2 + L_3 \sim 2L_1 + L_4 \sim 4L_1 - L_2$. Then $\text{Cl}(X) = \mathbb{Z}[L_1] \oplus \mathbb{Z}[L_2]$ and $\tau(X) = 1$. 

10
Thus, the surfaces $19^o$ or $37^o$ are weakly minimal and their Fano–Weil index is 1. On the other hand, we have the following result:

**Theorem 3.12.** Let $X$ be a Du Val del Pezzo surface and let $d := K_X^2$. Suppose $X$ is weakly minimal, $d \geq 3$, and $\tau(X) = 1$. Then $X$ is one of the surfaces $19^o$ or $37^o$.

**Proof.** Observe that $\rho(X) \geq 2$ by Lemma 3.1. First, let us consider the case where $\rho(X) = 2$. In this case, the Mori cone $\text{NE}(X)$ is generated by two lines $L_1$ and $L_2$ such that $L_1 \cap L_2 \neq \emptyset$. Without loss of generality, we may assume that $L_1^2 \geq L_2^2$. Then

$$-K_X \sim_{\mathbb{Q}} \alpha_1 L_1 + \alpha_2 L_2$$

for some $\alpha_1 \in \mathbb{Q}_{>0}$ and $\alpha_2 \in \mathbb{Q}_{>0}$. Since $-K_X \cdot L_1 = -K_X \cdot L_2 = 1$ and $K_X^2 = d$, we get

$$\begin{cases} 
\alpha_1 + \alpha_2 = d, \\
\alpha_1 L_1^2 + \alpha_2 L_1 \cdot L_2 = 1, \\
\alpha_1 L_1 \cdot L_2 + \alpha_2 L_2^2 = 1.
\end{cases}$$

(3.13)

Let $\psi_1 : X \to Y_1$ and $\psi_2 : X \to Y_2$ be the contractions of the extremal rays that are generated by the lines $L_1$ and $L_2$, respectively.

Assume that $\psi_1$ is a conic bundle. Since $X$ is weakly minimal, by Lemma 2.11(i) we have $d \geq 4$. In particular, the anticanonical model of $X$ is an intersection of quadrics. Then for a general fiber $C_1$ of $\psi_1$ we have $C_1 \cdot L_2 = 1$ and $C_1 \sim 2 L_1$. Hence, $L_1 \cdot L_2 = 1/2$ and $L_2^1 = 0$. Then (3.13) gives $\alpha_2 = 2$, $\alpha_1 = d - 2$, $L_2^2 = 1 - d/4$. Clearly, we may assume that $d \leq 6$. If $d = 5$, then $L_2^2 = -1/4$ and $\psi_2$ is an $(1,4)$-contraction by Lemma 2.12. Thus $X$ is the surface $37^o$ in this case. If $d = 6$, then $\alpha_1 = 4$, $L_2^2 = -1/2$ and $\psi_2$ is an $(1,2)$-contraction. Hence, $2L_1 + 4L_2$ is a Cartier divisor, so that

$$-K_X \sim 2L_1 + 4L_2 = 2(L_1 + 2L_2),$$

which is impossible, since $\tau(X) = 1$. Finally, if $d = 4$, then $L_2^2 = 0$ and $\psi_2$ is also a conic bundle. Since $2L_1 + 2L_2$ is Cartier, we have $-K_X \sim 2L_1 + 2L_2$ and so $\tau(X) > 1$, a contradiction.

Thus, we may assume that both $\psi_1$ and $\psi_2$ are birational.

Each line $L_1$ and $L_2$ contains exactly one singular point of the surface $X$ by Lemma 2.12. Let $P_1$ be the singular point contained in $L_1$, and let $P_2$ be the singular point contained in $L_2$. By Lemma 2.12, the points $P_1$ and $P_2$ are singular points of types $A_{n_1}$ and $A_{n_2}$ for some positive integers $n_1$ and $n_2$. Then

$$-1 \quad \frac{1}{n_1 + 1} = \frac{1}{L_1^2} \geq \frac{1}{L_2^2} = -1 \quad \frac{1}{n_2 + 1},$$

by Lemma 2.12, so that $n_1 \geq n_2 \geq 1$.

Suppose that $P_1 \neq P_2$. Then $L_1 \cap L_2$ is a smooth point of the surface $X$, so that $L_1 \cdot L_2 = 1$. Then (3.13) gives

$$\begin{cases} 
\alpha_1 + \alpha_2 = d, \\
-\alpha_1 + \alpha_2(n_1 + 1) = n_1 + 1, \\
\alpha_1(n_2 + 1) - \alpha_2 = n_2 + 1.
\end{cases}$$

Note also that $d + n_1 + n_2 \leq 8$, since $\rho(\tilde{X}) = 10 - d$. Eliminating $\alpha_1$ and $\alpha_2$, we get

$$d(n_1 n_2 + n_1 + n_2) = 2n_1 n_2 + 3n_1 + 3n_2 + 4$$

This gives us the following solutions:

- $d = 4$, $n_1 = n_2 = 1$, $\alpha_1 = \alpha_2 = 2$, $-K_X \sim_{\mathbb{Q}} 2(L_1 + L_2)$,
- $d = 3$, $n_1 = n_2 = 2$, $\alpha_1 = \alpha_2 = 3/2$, $-K_X \sim_{\mathbb{Q}} \frac{3}{2}(L_1 + L_2)$,
- $d = 3$, $n_1 = 4$, $n_2 = 1$, Type($X$) = $A_4A_1$, $\alpha_1 = \frac{5}{3}$, $\alpha_2 = \frac{4}{3}$, $-K_X \sim_{\mathbb{Q}} \frac{1}{3}(5L_1 + 4L_2)$.
If \( d = 4 \), then \( 2(L_1 + L_2) \) is a Cartier divisor, which gives
\[
-K_X \sim 2(L_1 + L_2),
\]
which is impossible. If \( d = 3 \) and \( n_1 = n_2 = 2 \), then \( X \) is a cubic surface in \( \mathbb{P}^3 \), so that \( X \) contains a line \( L \) such that \( L \) passes through \( P_1 \) and \( P_2 \) and
\[
-K_X \sim L + L_2 + L
\]
which gives \( -K_X \sim_q 3L \), because \( -K_X \sim_q \frac{1}{3}(5L_1 + 4L_2) \). In this case, the divisor \( 3L \) is Cartier, so that \( -K_X \sim 3L \), which contradicts \( \tau(X) = 1 \). Thus, we conclude that \( d = 3, n_1 = 4 \) and \( n_2 = 1 \). Then \( X \) is the surface \([19] \). Hence, to proceed, we may assume that \( P_1 = P_2 \).

Let \( n = n_1 = n_2 \). Then \( L_1 = L_2 = -\frac{1}{n+1} \). Moreover, we have \( L_1 \cdot L_2 = \frac{k}{n+1} \) for some \( k \in \mathbb{Z}_{>0} \). Then \((3.13)\) gives \( \alpha_2 = \frac{d}{3} \) and \( 2(n+1) = d(k-1) \), so that
\[
-K_X \sim_q \frac{d}{3}(L_1 + L_2).
\]

Note also that \( d + n \leq 8 \), since \( \rho(\tilde{X}) = 10 - d \). Then \( d \neq 5 \) and \( d \neq 7 \), because \( 2(n+1) = d(k-1) \). Likewise, if \( d = 6 \), then \( n = 2 \), so that \( -K_X \sim_q 3(L_1 + L_2) \) and \( \text{Cl}(X) \) is torsion free by Lemma \([2,9] \) which gives \( -K_X \sim 3(L_1 + L_2) \), which contradicts \( \tau(X) = 1 \). Hence, either \( d = 3 \) or \( d = 4 \).

Suppose that \( d = 4 \). Then \( n = 3 \), because \( 2(n+1) = d(k-1) \) and \( d + n \leq 8 \). Since \( \rho(X) = 2 \), we see that \( X \) has a singular point of type \( A_1 \). On the other hand, we have \( -K_X \sim_q 2(L_1 + L_2) \). Since \( \tau(X) = 1 \), we have \( -K_X \not\sim 2(L_1 + L_2) \), so that \( -K_X + 2(L_1 + L_2) \) is a non-trivial torsion element in \( \text{Cl}(X) \). Now, applying Lemma \([2,9] \), we obtain a double cover \( \pi: Y \rightarrow X \) that is étale outside of the point \( L_1 \cap L_2 \). Then \( Y \) is a del Pezzo surface of degree \( 8 \) such that it contains two singular points of type \( A_1 \), which is absurd. This shows that \( d \neq 4 \).

Therefore, we see that \( d = 3 \). Since \( 2(n+1) = d(k-1) \) and \( d + n \leq 8 \), we have \( n = 2 \) or \( n = 5 \). Since \( X \) is a cubic surface in \( \mathbb{P}^3 \), it contains a line \( L \) such that
\[
-K_X \sim L + L_2 + L,
\]
so that \( L \sim_q \frac{1}{2}(L_1 + L_2) \), because \( -K_X \sim_q \frac{2}{3}(L_1 + L_2) \). This gives \( -K_X \sim_q 3L \). But \( -K_X \not\sim 3L \). In particular, we have \( n \neq 2 \), because \( 3L \) is a Cartier divisor if \( n = 2 \). We conclude that \( n = 5 \).

Now, using Lemma \([2,9] \), we conclude that there is a finite Galois cover \( \pi: Y \rightarrow X \) of degree \( r \geq 2 \), which is étale outside of the point \( L_1 \cap L_2 \). Here, \( r \) be the order of the torsion divisor \( K_X + 3L \). By construction, the surface \( Y \) is a del Pezzo surface of degree \( rd \), so that either \( r = 2 \) or \( r = 3 \). If \( r = 3 \), then \( Y \cong \mathbb{P}^2 \), which is impossible, since \( \rho(Y) \geq \rho(X) = 2 \). Thus, we have \( r = 2 \). Then
\[
-K_X \sim 3L - (K_X + 3L) \sim 3L - (K_X + 3L) + 4(K_X + 3L) \sim 3L + 3(K_X + 3L) \sim 3(K_X + 4L),
\]
which is impossible, since \( \tau(X) = 1 \). The obtained contradiction shows that \( \rho(X) \neq 2 \).

We see that \( \rho(X) \geq 3 \) and \( X \) is singular. Then \( d \leq 6 \).

Let \( \psi: X \rightarrow Y \) be an extremal Mori contraction. Since \( \rho(X) \geq 3 \), the morphism \( \psi \) is birational, so that \( \psi \) is a \((1, m)\)-contraction of a line \( L \subset X \) by Lemma \([2,12] \). Then \( Y \) is a weakly minimal Du Val del Pezzo surface such that \( K_Y^2 = d + m \) with \( \rho(Y) = \rho(X) - 1 \geq 2 \) (see Remark \([3,3] \)). In particular, we have \( d + m \neq 7 \), because a Du Val del Pezzo surface of degree \( 7 \) is not weakly minimal (see Example \([2,3] \)). Note that \( m \geq 2 \), since \( X \) is weakly minimal.

Consider the case \( d = 6 \). Using the Noether formula, we see that \( \rho(X) = 3 \) and \( \text{Type}(X) = A_1 \). Then \( m = 2 \), \( K_Y^2 = 8 \), \( \rho(Y) = 2 \), so that \( Y \cong \mathbb{P}^1 \times \mathbb{P}^1 \). Then \( K_X \sim \psi^*K_Y + 2L \) is divisible by \( 2 \), which is a contradiction. Thus, we have \( d \neq 6 \).

Consider the case \( d = 5 \). Since \( d + m \neq 7 \), we have \( m > 2 \). Then \( \rho(X) = 3 \) and \( \text{Type}(X) = A_2 \) by the Noether formula, so that \( X \) is not weakly minimal by \([7, \text{Proposition 8.5}] \). This contradicts our assumption.
Consider the case $d = 4$. Then $m \neq 3$, since $d + m \neq 7$. If $m > 3$, it follows from the Noether formula that $m = 4$, $\rho(X) = 3$ and Type($X$) = $A_3$, so that $Y \cong \mathbb{P}^1 \times \mathbb{P}^1$, which gives

$$-K_X \sim 2(\tilde{F}_1 + \tilde{F}_2),$$

where $\tilde{F}_1$ and $\tilde{F}_2$ are proper transforms on $X$ of the curves in $Y$ of bi-degree $(1,0)$ and $(0,1)$ that contains $\psi(L)$, respectively. $\tilde{F}_1 \tilde{F}_2$. This contradicts our assumption $\tau(X) = 1$. So, we see that all extremal contractions on $X$ are birational $(1,2)$-contractions. Then $\tau(Y) > 1$, since we already dealt with sextic del Pezzo surfaces. By Theorem 3.8, we see that $Y$ is one of the surfaces $\text{45}^0$, $\text{44}^0$, $\text{43}^0$. If $Y$ is the surface $\text{43}^0$, then it has a birational $(1,3)$-contraction, so that $X$ also has a birational $(1,3)$-contraction by Corollary 2.14, which is a contradiction. Then $Y$ is one of the surfaces $\text{45}^0$ or $\text{44}^0$. By Lemma 2.9(iii) we have

$$-K_Y \sim 2 \sum_{i=1}^s a_i M_i$$

for some lines $M_1, \ldots, M_s$ on the surface $Y$ and some integers $a_1, \ldots, a_s$. Since $\psi(L)$ is a smooth point of $Y$ that does not lie on a line by Corollary 2.14, we obtain

$$-K_X \sim 2 \sum_{i=1}^s a_i \tilde{M}_i - 2L \sim 2 \left( \sum_{i=1}^s a_i \tilde{M}_i - L \right),$$

where $\tilde{M}_i$ is a proper transform on $X$ of the line $M_i$. This contradicts our assumption $\tau(X) = 1$.

Finally, we consider the case $d = 3$. Then $m \neq 4$, since $d + m \neq 7$. Moreover, since $X$ is weakly minimal, there exists no dominant morphisms from $X$ to a curve by Lemma 2.10(iii) and the same holds for $Y$. Using this, we conclude that $m \neq 5$. Thus, we have the following possibilities:

- either $K_Y^2 = 5$ and $m = 2$,
- or $K_Y^2 = 6$ and $m = 3$.

Moreover, if $K_Y^2 = 5$, then $Y$ is not the surface $\text{37}^0$, because del Pezzo surface $\text{37}^0$ admits a dominant morphism to $\mathbb{P}^1$ (see Example 3.10). Therefore, we conclude that $\tau(Y) > 1$, because we already dealt with weakly minimal Du Val del Pezzo surfaces of degree 5 and 6.

Now, using Theorem 3.8, we see that $K_Y^2 \neq 5$, because $\rho(Y) > 1$. Therefore, we have $K_Y^2 = 6$. Then $Y$ is the surface $\text{43}^0$, $\text{44}^0$, or $\text{45}^0$ again by Theorem 3.8. If $Y$ is one of the surfaces $\text{44}^0$ or $\text{45}^0$ then the map $Y \to \mathbb{P}^1$ given by

$$(y_1 : y_1' : y_2') \mapsto (y_1 : y_1')$$

is a morphism, which is a contradiction. Thus, we see that $Y$ is the surface $\text{43}^0$. Then $X$ is a cubic surface such that Type($X$) = $2A_2$. Now, using [6], we conclude that $X$ is one of the surfaces $\text{23}^0$ so that $\tau(X) = 3$ by Theorem 3.8 which contradicts our assumption.

4. THE PROOF OF MAIN THEOREM: HIGHER DEGREE CASES

Let $X$ be a Du Val del Pezzo surface of degree $d$ whose automorphism group $\text{Aut}(X)$ is infinite. If $d \geq 8$, then $X$ is either $\mathbb{P}^2$, $\mathbb{P}^1 \times \mathbb{P}^1$ or $F_1$. In each of this case, the corresponding automorphism group is well-known and listed in Big Table (cases $\text{53}^0$, $\text{52}^0$, $\text{50}^0$ respectively).

If $d \leq 7$, we have an $\text{Aut}^0(X)$-equivariant diagram (2.1). If $d = 7$, then $X$ is one of the del Pezzo surfaces $\text{48}^0$ and $\text{49}^0$ and the morphism $\varphi$ in (2.1) is a blow up of two (possibly infinitely near) points. From this we obtain the following

**Lemma 4.1.** Let $X$ be a Du Val del Pezzo surface of degree 7, and let $U$ be the complement in the surface $X$ to the union of all lines. Then Main Theorem holds for $X$, the subset $U$ is the open orbit of the group $\text{Aut}^0(X)$, and $U \cong \mathbb{A}^2$. 

13
All del Pezzo surfaces of degree 6 have infinite automorphism groups, so that all of them appear in our Big Table. These are the del Pezzo surfaces $42^\circ$, $43^\circ$, $44^\circ$, $45^\circ$, $46^\circ$ and $47^\circ$. Going through these six cases one by one, we obtain

**Lemma 4.2.** Let $X$ be a Du Val del Pezzo surface of degree 6, and let $U$ be the complement in the surface $X$ to the union of all lines. Then Main Theorem holds for $X$, the subset $U$ is the open orbit of the group $\text{Aut}^0(X)$, and $U \cong \mathbb{A}^2$ in the cases $42^\circ$, $43^\circ$, $44^\circ$ and $45^\circ$.

**Proof.** If $X$ is the surface $47^\circ$ then $\varphi$ in (2.1) is a blow up of three distinct non-collinear points, so that $X$ is toric and $\text{Aut}^0(X) \cong \mathbb{G}_m^2$.

Likewise, if $X$ is the surface $45^\circ$ then $\varphi$ is the blow up of three distinct collinear points in $\mathbb{P}^2$. Using this, it is not hard to see that $\text{Aut}^0(X) \cong \mathbb{G}_m^2 \rtimes \mathbb{G}_m$ in this case.

For infinitely near points we use the notation of $11$.

If $X$ is the surface $42^\circ$ then the morphism $\varphi$ is the blow up of three infinitely near collinear points $P_1 \prec P_2 \prec P_3$ in the plane $\mathbb{P}^2$ in the notations of $11$, which implies that $\text{Aut}^0(X) \cong \mathbb{B}_3$.

Similarly, if $X$ is the surface $43^\circ$ then $\varphi$ is the blow up of three infinitely near non-collinear points $P_1 \prec P_2 \prec P_3$, which implies that $\text{Aut}^0(X) \cong \mathbb{B}_2 \times \mathbb{B}_2$.

Finally, if $X$ is the surface $44^\circ$ then $\varphi$ is the blow up of three non-collinear points $P_1 \prec P_2 \prec P_3$, so that $P_1$ and $P_2$ are distinct, but $P_3 \succ P_1$. Hence, in this case, we have $\text{Aut}^0(X) \cong \mathbb{B}_2 \times \mathbb{G}_m$.

The last assertions follow from Corollary 2.11 in the cases $42^\circ$, $43^\circ$, $44^\circ$ and $45^\circ$, and it follows from Lemma 4.1 in the cases $46^\circ$ and $47^\circ$. $\square$

Similarly, all singular del Pezzo surfaces of degree 5 also have infinite automorphism groups. These are the surfaces $36^\circ$, $37^\circ$, $38^\circ$, $39^\circ$, $40^\circ$ and $41^\circ$ in Big Table.

**Lemma 4.3.** Let $X$ be a Du Val del Pezzo surface of degree 5, and let $U$ be the complement in the surface $X$ to the union of all lines. Then Main Theorem holds for $X$, the subset $U$ is the open orbit of the group $\text{Aut}^0(X)$ in the cases $36^\circ$, $37^\circ$, $38^\circ$, $39^\circ$, $40^\circ$ and $41^\circ$, and $U \cong \mathbb{A}^2$ in the cases $36^\circ$, $37^\circ$.

**Proof.** If $X$ is weakly minimal and $\tau(X) > 1$, then $X$ is the surface $36^\circ$ by Theorems 3.12 and 3.8. The group $\text{Aut}(X)$ contains the following three elements

\[
(y_1 : y_2 : y_3 : y_5) \rightarrow (y_1 : y_2 + y_1^2 : y_3 : y_5 - y_1^2 - 3y_1y_2 - 3y_1y_3)
\]
\[
(y_1 : y_2 : y_3 : y_5) \rightarrow (y_1 : y_2 + y_1y_3 : y_3 - y_1y_2 - 2y_2y_3)
\]
\[
(y_1 : y_2 : y_3 : y_5) \rightarrow (y_1 : y_2 + y_1y_3 : y_3 - 2y_2y_3)
\]

generating a subgroup isomorphic to $U_3$ and an one-dimensional torus

\[
(y_1 : y_2 : y_3 : y_5) \rightarrow (y_1 : y_2 : \lambda y_3 : \lambda^{-1}y_5).
\]

From this we can conclude that $\text{Aut}^0(X) \cong U_3 \rtimes \mathbb{G}_m$ (cf. Corollary 2.2, see also Corollary 3.8).

If $X$ is weakly minimal and $\tau(X) = 1$, then $X$ is the del Pezzo surface $37^\circ$ by Theorem 3.12 and its $\text{Aut}^0(X)$-equivariant embedding $X \hookrightarrow \mathbb{P}^1 \times \mathbb{P}^2$ is described in Example 3.10. In this case, the group $\text{Aut}(X)$ contains a two-dimensional unipotent subgroup

\[
(v_0 : v_1; u_0 : u_1 : u_2) \rightarrow (v_0 - (a_1^2 + a_2)v_1 ; v_1; u_0 + a_1u_2 : u_1 - 2a_1u_0 + a_2u_2 : u_2)
\]

and a one-dimensional torus

\[
(v_0 : v_1; u_0 : u_1 : u_2) \rightarrow (v_0 : t^{-2}v_1; tu_0 : t^2u_1 : u_2),
\]

where $a_1, a_2 \in \mathbb{K}$ and $t \in \mathbb{K}^*$. This implies that $\text{Aut}(X) \cong \mathbb{G}_m^2 \rtimes \mathbb{G}_m$ as required.

We may assume that $X$ is not weakly minimal. Then there is a birational morphism $\psi : X \rightarrow Y$ such that $Y$ is one of the surfaces $42^\circ$, $43^\circ$, $44^\circ$, $45^\circ$ and $\psi$ is a blow up of a smooth point $P \in Y$. 

14
By Corollary 2.14 and Lemma 4.2, the point $P$ is contained in the open orbit of the group $\text{Aut}^0(Y)$. Since $\text{Aut}^0(X)$ is the connected component of the stabilizer in $\text{Aut}^0(Y)$ of the point $P$, this gives the required description of the group $\text{Aut}^0(X)$ in Big Table.

The last assertions follow from Corollary 2.11 in the cases 36, 37, and it follows from Lemma 4.2 in the cases 38, 39, 40.

Let us conclude this section by proving Main Theorem for Du Val del Pezzo surfaces of degree 4.

**Proposition 4.4.** Main Theorem holds for Du Val del Pezzo surfaces of degree 4.

**Proof.** Let $X$ be Du Val del Pezzo surface of degree 4 such that the group $\text{Aut}(X)$ is infinite. Suppose that $X$ is not weakly minimal. Then there exists a birational morphism $\psi : X \to Y$ such that $Y$ is a singular quintic Du Val del Pezzo surface, and $\psi$ is a blow up of a smooth point $P \in Y$, which is not contained in a line by Corollary 2.14. Observe that the group $\text{Aut}(Y)$ is the connected component of the stabilizer in $\text{Aut}^0(Y)$ of the point $P$. Using Lemma 4.3 we see that $Y$ must be one of the surfaces 36, 37, 38 and $P$ must be contained in the open orbit of the group $\text{Aut}^0(Y)$.

This implies that $X$ is one of the surfaces 27, 32, 33 respectively. Now, it is not hard to check that $\text{Aut}^0(X) \cong \mathbb{G}_m$ in the cases 32 and 33, and $\text{Aut}^0(X) \cong \mathbb{B}_2$ in the case 27.

Hence, we may assume that the surface $X$ is weakly minimal. Then $\tau(X) > 1$ by Theorem 3.12. Using Theorem 3.8 we see that $X$ is one of the surfaces 24, 25, 26, 28, 29, 30, 31, 34, 35, 36. Let us show that $X$ is infinite, and $\text{Aut}^0(X)$ is described in Big Table.

Let $X$ be the surface 24. Then $X$ is embedded into $\mathbb{P}(1,2,3,4)$ as a hypersurface that is given by the equation $y_3^2 = y_1^3 + y_2^2 y_4$. This embedding is $\text{Aut}^0(X)$-equivariant by Remark 3.5. Observe that $\text{Aut}^0(X)$ contains transformations

$$(y_1 : y_2 : y_3 : y_4) \mapsto (y_1 : y_2 + a y_1 : y_3 + b y_1 : y_4 + 3 a y_2 + 3 a^2 y_1^2 y_2 + 2 b y_1 y_3 + (a^3 + b^2) y_1^3),$$

where $a \in \mathbb{k}$ and $b \in \mathbb{k}$. These transformations generates a subgroup in $\text{Aut}^0(X)$ isomorphic to $\mathbb{G}_a^2$. Moreover, the surface $X$ also admits an action of a one-dimensional torus which acts diagonally:

$$(y_1 : y_2 : y_3 : y_4) \mapsto (t^2 y_1 : t^2 y_2 : t^3 y_3 : t^2 y_4),$$

where $t \in \mathbb{G}_m$. The described transformations generate a subgroup that is isomorphic to $\mathbb{G}_a^2 \times \mathbb{G}_m$. Since $X$ has a singularity of type $D_5$, it is not toric, so that $\text{Aut}^0(X) \cong \mathbb{G}_a^2 \times \mathbb{G}_m$ (cf. Corollary 3.8).

Now we suppose that $X$ is the surface 25. Then $\text{Aut}(X)$ contains transformations

$$\gamma(a) : (y_1 : y_2 : x_2 : x_3) \mapsto (y_1 : y_2 : x_2 + a y_1 y_2 : x_3 + 2 a y_1 x_2 + a^2 y_1^2 y_2)$$

for every $a \in \mathbb{k}$. These transformations generates a proper subgroup in $\text{Aut}^0(X)$ isomorphic to $\mathbb{G}_a^2$. Moreover, the surface $X$ also contains transformations

$$\delta(t_1, t_2) : (y_1 : y_2 : x_2 : x_3) \mapsto (t_1^2 t_2 y_1 : t_1 t_2^2 y_2 : t_1^3 t_2^2 x_2 : t_1^2 t_2 x_3)$$

for every $t_1 \in \mathbb{k}^*$ and $t_2 \in \mathbb{k}^*$. They generates a subgroup isomorphic to $\mathbb{G}_m^2$. Observe that

$$\gamma(a) \circ \delta(t_1, t_2) = \delta(t_1, t_2) \circ \gamma_{a t_2}.$$  

Therefore, all described transformations generate a subgroup in $\text{Aut}^0(X)$ isomorphic to $\mathbb{B}_2 \times \mathbb{G}_m$. Then $\text{Aut}^0(X) \cong \mathbb{B}_2 \times \mathbb{G}_m$, because $X$ does not admit an effective $\mathbb{G}_a^2$-action by Corollary 2.11.

Now we suppose that 28. Then the group $\text{Aut}(X)$ contains transformations

$$(y_1 : y_2 : x_2 : x_3) \mapsto (t y_1 : t^2 y_2 : t^3 x_2 + a t^3 y_1 y_2 : t^3 x_3 + 2 a t^3 y_1 x_2 + a^2 t^3 y_1^2 y_2)$$

for any $a \in \mathbb{k}$ and $t \in \mathbb{k}^*$. These transformations generate a subgroup in $\text{Aut}^0(X)$ isomorphic to $\mathbb{B}_2$. Since all three lines on $X$ pass through one point, $X$ is not toric. Hence, $\text{rk Aut}^0(X) = 1$. The surface $X$ does not admit an effective $\mathbb{G}_a^2$-action by Corollary 2.11, so that $\dim \text{Aut}^0(X) = 2$, which implies $\text{Aut}^0(X) \cong \mathbb{B}_2$. 

15
Let $X$ be one of the surfaces $29^o$ or $30^o$. Then $\#(X) = 4$. Let $L_1, L_2, L_3, L_4$ be the lines in $X$. Recall that $X$ is an intersection of two quadrics in $\mathbb{P}^4$. We have

$$L_1 + L_2 + L_3 + L_4 \sim -K_X,$$

so that $L_1 + L_2 + L_3 + L_4$ is cut out by a hyperplane $H \subset \mathbb{P}^4$. On the other hand, this curve form a combinatorial cycle. Thus, if $L$ exists an exact sequence of groups $X$, then this action is trivial on each line among $L_1, L_2, L_3$ and $L_4$, so that it is trivial on $H$, which implies that the closure of any one-dimensional $\mathbb{G}_a$-orbit is a line. The latter is impossible, since $X$ contains finitely many lines. Therefore, we conclude that the surface $X$ does not admit an effective action of the group $\mathbb{G}_a$. On the other hand, the equations of $X$ are binomial. This implies that $X$ admits a diagonal action of two-dimensional torus. Hence, $\text{Aut}^0(X) \cong \mathbb{G}_m^2$.

Let $X$ be one of the surfaces $35^o$ or $34^o$. Then $X$ contains two lines $L_1$ and $L_2$ such that the intersection $L_1 \cap L_2$ is a smooth point of $X$, and there exist an $\text{Aut}^0(X)$-equivariant diagram

$$\begin{array}{ccc}
X & \xrightarrow{\alpha} & \widehat{X} \\
\downarrow & & \downarrow \\
Y & \xrightarrow{\beta} & Y
\end{array}$$

where $\alpha$ is a blow up of the point $L_1 \cap L_2$, and $\beta$ is the birational contraction of the proper transforms of the lines $L_1$ and $L_2$. Then we have the following possibilities:

- if $X$ is the surface $35^o$, then $Y$ is a cubic surface such that $\text{Type}(Y) = A_4 A_1$;
- if $X$ is the surface $34^o$, then $Y$ is a cubic surface such that $\text{Type}(Y) = 2A_2$.

Hence, it follows from Corollary 7.4 that $Y$ does not admit an effective action of the group $\mathbb{G}_a$. Since $X$ contains three lines passing through one point, it is not toric. One the other hand, it is easy to see that $X$ admits an effective diagonal action of a one-dimensional torus.

To complete the proof, we may assume that $X$ is one of the surfaces $26^o$ or $31^o$. By Lemma 2.10(ii) there is a double cover $\pi: X \to \mathbb{P}^1 \times \mathbb{P}^1$ branched over a curve $B$ of degree $(2, 2)$. By construction, this double cover is $\text{Aut}^0(X)$-equivariant, and the curve $B$ is $\text{Aut}^0(X)$-invariant. Therefore, there exists an exact sequence of groups

$$1 \longrightarrow \mu_2 \longrightarrow \text{Aut}(X) \longrightarrow \text{Aut}(\mathbb{P}^1 \times \mathbb{P}^1, B).$$

If $X$ is the surface $26^o$, then $B$ is a union of irreducible smooth curves of degrees $(1, 1)$, $(1, 0)$, $(0, 1)$, which intersect in one point, which implies that

$$\text{Aut}(\mathbb{P}^1 \times \mathbb{P}^1, B) \cong \mathbb{B}_2 \rtimes \mu_2.$$  

This can be shown by taking linear projection $\mathbb{P}^1 \times \mathbb{P}^1 \dashrightarrow \mathbb{P}^2$ from the singular point $\text{Sing}(B)$, where we consider $\mathbb{P}^1 \times \mathbb{P}^1$ as a quadric in $\mathbb{P}^3$. Thus, in this case, we have $\text{Aut}^0(X) \cong \mathbb{G}_a \rtimes (\mathbb{G}_m^2)$, since $\text{Aut}(X)$ contains a subgroup isomorphic to $\mathbb{G}_a \rtimes \mathbb{G}_m$, generated by transformations

$$(y_1 : y_1' : y_2 : y_2') \longmapsto (y_1 : ty_1' : t^2 y_2 + at^2 y_1' : t^4 y_2' + 2at^4 y_2 + a^2 t^4 y_1'),$$

where $a \in \mathbb{k}$ and $t \in \mathbb{k}^*$. Similarly, if $X$ is the surface $31^o$ then

$$\text{Aut}(\mathbb{P}^1 \times \mathbb{P}^1, B) \cong \mathbb{G}_a \rtimes \mu_2,$$

because $B$ is a union of two irreducible smooth curves of degree $(1, 1)$, which intersect in one point. In this case, we have $\text{Aut}^0(X) \cong \mathbb{G}_a$, since the $\mathbb{G}_a$-action lifts from $\mathbb{P}^1 \times \mathbb{P}^1$ to the surface $X$.  

**Corollary 4.5.** Main Theorem holds del Pezzo surfaces of degree $\geq 4$.  

---
5. Del Pezzo Surfaces of Degree 1

In this section, we prove Main Theorem for del Pezzo surfaces of degree 1.

Proposition 5.1. Main Theorem holds for del Pezzo surfaces of degree 1.

We start with

Lemma 5.2. Let $X$ be a Du Val del Pezzo surface of degree 1. Then $X$ does not admit effective actions of the group $\mathbb{G}_a$.

Proof. Suppose that $X$ admit an effective $\mathbb{G}_a$-action. Let $\Phi: X \dashrightarrow \mathbb{P}^1$ be the anticanonical map. It is $\text{Aut}(X)$-equivariant, and all its fibers are reduced irreducible curves of arithmetic genus 1. Since $\mathbb{G}_a$ cannot effectively act on a smooth elliptic curve, we conclude that $\mathbb{G}_a$ acts non-trivially on the base of $\Phi$. Thus, there is exactly one $\mathbb{G}_a$-invariant fiber, say $C$. Any fiber of $\Phi$ different from $C$ is a smooth elliptic curve. Thus we have

$$\rho(X) + 2 = \chi(X) = \chi(C) - 1,$$

so that $\chi(C) = \rho(X) + 3 \geq 4$. But $\chi(C) \leq 2$, because $C$ is a curve of arithmetic genus 1. \hfill \Box

Our next step in proving Main Theorem for del Pezzo surfaces of degree 1 is the following

Lemma 5.3. If $X$ is one of the surfaces $\mathbb{1}$, $\mathbb{2}$, $\mathbb{3}$, $\mathbb{4}$ then $\text{Aut}^0(X) \cong \mathbb{G}_m$.

Proof. By Lemma 5.2 these surfaces do not admit a $\mathbb{G}_a$-action and they are not toric because their singularities are not cyclic quotient. On the other hand, it is easy to see that each of these surfaces admits a $\mathbb{G}_m$-action. \hfill \Box

We also need the following easy local fact.

Lemma 5.4. Let $(X \ni P)$ be a Du Val singularity that contains a reduced irreducible curve $C$ such that $C$ is a Cartier divisor on $X$, and the singularity $(C \ni P)$ is a simple cusp.

(i) If $(X \ni P)$ is of type $A_n$, then $n \leq 2$.

(ii) If $(X \ni P)$ is of type $D_n$ with $n \geq 5$, then $(X \ni P)$ can be given by the equation

$$x^2 + y^2z + z^{n-1} = 0,$$

so that $C$ is cut out by $z = y + \phi(x, y, z)$, where $\text{mult}_0(\phi) \geq 2$.

Corollary 5.5. Let $X$ be a surface admitting an effective $\mathbb{G}_m$-action, let $C$ be a $\mathbb{G}_m$-invariant reduced irreducible curve in $X$ that is a Cartier divisor on $X$, and let $P$ be its singular point. Suppose that $X$ has Du Val singularity of type $D_n$ at $P$, and $C$ has a simple cusp at $P$. Then $n = 4$.

Now, we are ready to prove Proposition 5.1

Proof of Proposition 5.1. Let $X$ be a Du Val del Pezzo surface of degree 1. Then $X$ does not admit an effective $\mathbb{G}_a$-action by Lemma 5.2. Thus, the group $\text{Aut}(X)$ is infinite if and only if $X$ admits an effective action of the group $\mathbb{G}_m$.

Suppose that $X$ admits an effective $\mathbb{G}_m$-action. By Lemma 5.3 to complete the proof, it is enough to show that $X$ is one of the surfaces $\mathbb{1}$, $\mathbb{2}$, $\mathbb{3}$, $\mathbb{4}$.

Let $\Phi: X \dashrightarrow \mathbb{P}^1$ be the anticanonical map. It is $\mathbb{G}_m$-equivariant, and all its fibers are reduced irreducible curves of arithmetic genus 1. Since $\mathbb{G}_m$ cannot effectively act on a smooth elliptic curve, we conclude that $\mathbb{G}_m$ acts non-trivially on the base of $\Phi$. There are exactly two $\mathbb{G}_m$-invariant fibers. Denote them by $C_1$ and $C_2$. Any fiber of $\Phi$ different from $C_1$ and $C_2$ is a smooth elliptic curve. Thus we have

$$\rho(X) + 2 = \chi(X) = \chi(C_1) + \chi(C_2) - 1,$$
so that \( \chi(C_1) + \chi(C_2) = \rho(X) + 3 \geq 4 \). Since \( \chi(C_i) \leq 2 \), we have \( \rho(X) = 1 \) and \( \chi(C_1) = \chi(C_2) = 2 \). This means in particular that \( C_1 \) and \( C_2 \) are cuspidal curves of arithmetic genus 1.

Let \( P_1 \) be the singular point of \( C_i \). Then

\[ \emptyset \neq \text{Sing}(X) \subset \{ P_1, P_2 \} \]

The singularity of the surface \( X \) at the point \( P_1 \) is of type \( A_{n_1}, D_{n_1} \) or \( E_{n_1} \) for some \( n_1 \geq 1 \). Likewise, if \( X \) is singular at \( P_2 \), then \( P_2 \) is a singular point of type \( A_{n_2}, D_{n_2} \) or \( E_{n_2} \) for some \( n_2 \geq 0 \), where \( n_0 = 0 \) simply means that the point \( P_1 \) is the only singular point of the del Pezzo surface \( X \). Without loss of generality, we may assume that \( n_1 \geq n_2 \). Since \( \rho(X) = 1 \), \( n_1 + n_2 = 8 \) and \( n_1 \geq 4 \).

Now, using Corollary 5.5 we obtain the following possibilities for \( \text{Type}(X) \): \( E_8 \), \( E_7 A_1 \), \( E_6 A_2 \), \( 2D_4 \). But \( X \) is uniquely determined by \( \text{Type}(X) \) and the fact that \( | - K_X | \) has two singular curves that are both cuspidal. This follows from [31, Theorem 1.2] and [31, Table 4.1], see also Remark B.5. Thus, we conclude that \( X \) is one of the surfaces \( 2^* 3^* 4^* \) and \( 3^* 4^* \) (see e.g. [31 Satz 2.11]).

Let us conclude this section by an observation that the surfaces \( 2^* 3^* 4^* \) can be obtained as finite quotients of other surfaces in Big Table. The surface \( 2^* \) is the quotient of the surface \( 11^* \) by \( \mathbf{\mu}_2 \). The surface \( 3^* \) is the quotient of the cubic surface \( 22^* \) by \( \mathbf{\mu}_3 \), and \( 4^* \) is the quotient of a special member of the family \( 35^* \) by \( \mathbf{\mu}_2 \times \mathbf{\mu}_2 \). In all the cases the action of the group is free outside the singular locus. This observation can be used to obtain the description of the surfaces \( 2^* 3^* 4^* \) and \( 3^* 4^* \).

To show this one can look at the exact sequence

\[ 0 \longrightarrow \text{Pic}(X) \xrightarrow{\alpha} \text{Cl}(X) \xrightarrow{\beta} \bigoplus_{P \in X} \text{Cl}(X, P), \]

where \( \text{Cl}(X, P) \) is the local Weil divisor class group of the point \( P \in X \). The map \( \alpha \) is a primitive embedding. Hence, we have \( \text{Cl}(X) = \text{Pic}(X) \oplus \text{Cl}(X)_{\text{tors}} \). By Corollary B.6, we have

\[ \text{Cl}(X)_{\text{tors}} \neq 0. \]

By Lemma 2.9(b), the group \( \text{Cl}(X)_{\text{tors}} \) defines a Galois abelian cover \( \pi: X' \rightarrow X \) which is étale outside of the locus \( \text{Sing}(X) \) and whose degree is \( | \text{Cl}(X)_{\text{tors}} | \). Using the local description of such covers (see [28, 31]), we see that \( \text{Type}(X') = E_6, D_4, 2A_1 \) in the cases \( 2^*, 3^*, 4^* \) respectively.

### 6. Del Pezzo surfaces of degree 2

In this section, we prove Main Theorem for del Pezzo surfaces of degree 2. To do this, we need one (probably known) result about singular cubic and quartic curves (cf. [19, 30]).

**Proposition 6.1.** Let \( C \) be a reduced cubic or quartic curve in \( \mathbb{P}^2 \) such that \( \text{Aut}(\mathbb{P}^2, C) \) is infinite. Then the curve \( C \) and the group \( \text{Aut}^0(\mathbb{P}^2, C) \) are given in the following table:

| Equation of the curve \( C \) up to the action of \( \text{PGL}_3(\mathbb{k}) \) | \( \text{Aut}^0(\mathbb{P}^2, C) \) |
|---|---|
| \( x_0 x_1(x_0 + x_1) = 0 \) | \( \mathbb{G}_m \times \mathbb{G}_m \) |
| \( x_0 x_1 x_2 = 0 \) | \( \mathbb{G}_m \) |
| \( x_0(x_0 x_2 + x_1^2) = 0 \) | \( \mathbb{B}_2 \) |
| \( x_0^2 x_2 + x_1^3 = 0 \) | \( \mathbb{G}_m \) |
| \( x_2(x_0 x_2 + x_1^2) = 0 \) | \( \mathbb{G}_m \) |
| \( x_0 x_1(x_0 - x_1)(x_0 - \lambda x_1) = 0 \) for \( \lambda \in \mathbb{k} \setminus \{0, 1\} \) | \( \mathbb{B}_2 \) |
| \( x_0(x_0^2 x_2 + x_1^3) = 0 \) | \( \mathbb{G}_m \) |
If $C$ is one of the curves in the table, we can explicitly describe $\text{Aut}^0(\mathbb{P}^2, C)$ by finding all elements in $\text{Aut}(\mathbb{P}^2) \cong \text{PGL}_3(\mathbb{k})$ that leaves every irreducible component of the curve $C$ invariant. For example, if $C$ is given by $x_0x_1(x_0 + x_1) = 0$, then $\text{Aut}^0(\mathbb{P}^2, C)$ consists of the transformations

$$(x_0 : x_1 : x_2) \mapsto (tx_0 : tx_1 : x_2 ± tx_0 + bx_1)$$

for any $t \in \mathbb{k}^*$, $a \in \mathbb{k}$ and $b \in \mathbb{k}$. Thus, in this case, we have $\text{Aut}^0(\mathbb{P}^2, C) \cong \mathbb{G}_a \times \mathbb{G}_m$ as required.

Similarly, if $C$ is given by $x_0(x_0x_2 + x_1^2) = 0$, then $\text{Aut}^0(\mathbb{P}^2, C)$ consists of the transformations

$$(x_0 : x_1 : x_2) \mapsto \left(t^2x_0 : tx_1 + ax_0 : x_2 ± \frac{2a}{t}x_1 ± \frac{a^2}{t^2}x_0\right)$$

for any $t \in \mathbb{k}^*$ and $a \in \mathbb{k}$, so that $\text{Aut}^0(\mathbb{P}^2, C) \cong \mathbb{G}_a \times (\eta(1))\mathbb{G}_m$. Likewise, if $C$ is the cubic $x_0^2x_2 + x_1^3 = 0$, then $\text{Aut}^0(\mathbb{P}^2, C)$ consists of the transformations $(x_0 : x_1 : x_2) \mapsto (t^3x_0 : t^2x_1 : x_2)$, where $t \in \mathbb{k}^*$. Thus, in this case, we have $\text{Aut}^0(\mathbb{P}^2, C) \cong \mathbb{G}_m$.

The computations are very similar in all remaining cases. For instance, if $C$ is the quartic curve that is given by $(x_0x_2 + x_1^2)^2 - x_4^4 = 0$, then $\text{Aut}(\mathbb{P}^2, C)$ consists of the transformations

$$(x_0 : x_1 : x_2) \mapsto \left(\zeta^2x_0 : \zeta x_1 ± \frac{\zeta a}{2} : x_2 ± ax_1 ± \frac{a^2}{4}x_0\right)$$

where $\zeta \in \{±1, ±i\}$ and $a \in \mathbb{k}$, which implies that $\text{Aut}(\mathbb{P}^2, C) \cong \mathbb{G}_a \times \mathbb{G}_m$, so that $\text{Aut}^0(\mathbb{P}^2, C) \cong \mathbb{G}_a$.

We leave the computations in the remaining cases to the reader.

Therefore, to complete the proof, we must show that $C$ is one of the curves listed in the table. If $C$ is the cubic curve, then $C$ must be singular. On the other hand, all singular cubic curves are already listed in the table except for the nodal one that is given by

$$x_2(x_0^2 + x_1^2) + x_1^2 = 0.$$ 

However, if $C$ is this curve, then $\text{Aut}(\mathbb{P}^2, C)$ is finite. Therefore, we may assume that $\deg(C) = 4$. Then we may have the following five cases:

(i) the curve $C$ is irreducible;  
(ii) $C = C_1 + C_2$, where $C_1$ is a line and $C_2$ is an irreducible cubic;  
(iii) $C = C_1 + C_2$, where $C_1$ and $C_2$ are irreducible conics;  
(iv) $C = C_1 + C_2 + C_3$, where $C_1$ and $C_2$ are lines, and $C_2$ is irreducible conic;  
(v) $C = C_1 + C_2 + C_3 + C_4$, where $C_1$, $C_2$, $C_3$ and $C_4$ are lines.

Moreover, by our assumption, the group $\text{Aut}(\mathbb{P}^2, C)$ contains a subgroup isomorphic to either $\mathbb{G}_a$ or $\mathbb{G}_m$ (or both). We deal with these two (slightly overlapping) possibilities separately.
Suppose that $\text{Aut}(\mathbb{P}^2, C) \supset \mathbb{G}_a$. Since each irreducible component is $\mathbb{G}_a$-invariant, we conclude that the case (ii) is impossible. Likewise, if $C$ is irreducible, then $C$ has a $\mathbb{G}_a$-open orbit $U \cong \mathbb{A}^1$. Hence the curve $C$ must be rational and its normalization morphism must be a homeomorphism, and the complement $C \setminus U$ is a single point, say $P$. The projection $C \rightarrow \mathbb{P}^1$ from $P$ must be $\mathbb{G}_a$-equivariant, so it is an isomorphism on $U$. This implies that $P$ is a triple point and there is exactly one line $L \subset \mathbb{P}^2$ such that $C \cap L = P$. We may assume that $P = (0 : 0 : 1)$ and $L$ is given by $x_0 = 0$. Then the equation of $C$ has the form $x_0^3x_2 + x_1^4 = 0$. But then $\text{Aut}^0(\mathbb{P}^2, C) \cong \mathbb{G}_m$, which is a contradiction. Hence, we conclude that case (i) is also impossible.

If we are in case (iii), then the $\mathbb{G}_a$-action of each irreducible conic $C_1$ and $C_2$ is effective, so that the intersection $C_1 \cap C_2$ consists of one point. In this case, in appropriate projective coordinates, the curve $C$ is given by

$$(x_1x_2 + x_0^2 + x_1^2)(x_1x_2 + x_0^2 - x_1^2) = 0,$$

so that $C$ is listed in the table as required.

If we are in case (iv) or case (v), then the closure of any one-dimensional $\mathbb{G}_a$-orbit is a line in the pencil generated by $C_1$ and $C_2$, which implies that $C$ is a union of four lines passing through one point. Hence, we are in case (v) and the curve $C$ can be given by

$$x_0x_1(x_0 - x_1)(x_0 - \lambda x_1) = 0$$

for some $\lambda \in \mathbb{k} \setminus \{0, 1\}$, so that $C$ is in the table as well.

To complete the proof, we may assume that $\text{Aut}(\mathbb{P}^2, C) \supset \mathbb{G}_m$. If $C$ is irreducible, then it can be given as the closure of the image of the map $t \mapsto (1 : t : t^4)$, so that $C$ is the curve $x_0^3x_2 - x_1^4 = 0$ in the table. Hence, we may assume that $C$ is reducible, i.e. we are not in case (i).

Suppose that $\mathbb{G}_m$ acts trivially on some irreducible component of the curve $C$. This component must be a line, so that we are in one of the cases (ii) (iv) or (v). Without loss of generality, we may assume that $\mathbb{G}_m$ acts trivially on the line $C_1$. Then there exists a $\mathbb{G}_m$-fixed point $O \in \mathbb{P}^2 \setminus C_1$, so that the closure of any $\mathbb{G}_m$-orbit in $\mathbb{P}^2$ is a line connecting $O$ and a point in $C_1$. This implies that we are in case (v) and the lines $C_2$, $C_3$, $C_4$ all pass through $O$, so that $C$ is given by

$$x_0x_1x_2(x_1 + x_2) = 0$$

in appropriate projective coordinates. This curve is in the table. Therefore, to complete the proof, we may assume that $\mathbb{G}_m$ acts effectively on each irreducible component of the curve $C$.

If we are in case (v), then each line among $C_1$, $C_2$, $C_3$ and $C_4$ meet the union of the remaining lines in at most two points. This implies that all these four lines must pass through one point. Such curve is in the table and we already met it earlier in the proof. Hence, case (v) is done.

Suppose that we are in case (iii), so that $C = C_1 + C_2$, where both $C_1$ and $C_2$ are irreducible conics. Then the intersection $C_1 \cap C_2$ consists of at most two points. Moreover, the intersection cannot consists of one point, since otherwise we would have $\text{Aut}(\mathbb{P}^2, C) \cong \mathbb{G}_a$. Hence, we see that the intersection $C_1 \cap C_2$ consists of exactly two points. Then the curve $C$ can be given by

$$(x_2^2 + x_0x_1)(x_2^2 + \lambda x_0x_1) = 0$$

for some $\lambda \in \mathbb{k} \setminus \{0, 1\}$. This curve is also in the table. Thus, case (iii) is also done.

Now we suppose that we are in case (iv). Then $C_1$ and $C_2$ are lines, and $C_3$ is a conic. Then

$$\#(C_3 \cap (C_1 \cup C_2)) \leq 2,$$

so that at least one of the lines $C_1$ and $C_2$ must be tangent to $C_3$. If only one of them is tangent, then $C$ can be given by $x_0x_1(x_0x_2 + x_1^2) = 0$. Similarly, if both lines are tangent to the conic $C_3$, then $C$ can be given by $x_0x_1(x_0x_1 + x_2^2) = 0$. In both subcases, the curve $C$ is in the table.
Finally, we suppose that we are in case (ii). Then $C_2$ is a cuspidal cubic curve. Now, choosing appropriate coordinates on $\mathbb{P}^2$, we may assume that $C_2$ is given by $x_0^2x_2 - x_1^3 = 0$, and the $\mathbb{G}_m$-action on $\mathbb{P}^2$ is described earlier in the proof. Then the $\mathbb{G}_m$-action on $C_2$ has exactly two fixed points: the points $(0 : 0 : 1)$ and $(1 : 0 : 0)$. If $C_1$ passes through both of them, then $C$ is given by

$$x_0x_1(x_0x_2 + x_1^2) = 0.$$ 

Similarly, if $(1 : 0 : 0) \in C_1$ and $(0 : 0 : 1) \notin C_1$, then the curve $C$ is given by $x_2(x_0^2x_2 + x_1^3) = 0$. Vice versa, if $(1 : 0 : 0) \notin C_1$ and $(0 : 0 : 1) \in C_1$, then the curve $C$ is given by $x_0(x_0^2x_2 + x_1^3) = 0$. In every subcase, we see that the quartic curve $C$ is listed in the table as required. □

Using Proposition 6.1, we immediately obtain

**Corollary 6.2.** **Main Theorem holds for del Pezzo surfaces of degree 2.**

**Proof.** Let $X$ be a Du Val del Pezzo surface of degree 2. Then $X$ is a hypersurface in $\mathbb{P}(1,1,1,2)$ that is given by $w^2 = \phi_4(x_0, x_1, x_2)$, where $\phi_4(x_0, x_1, x_2)$ is a homogeneous polynomial of degree 4. The natural projection to $\mathbb{P}^2$ gives a double cover $\pi: X \rightarrow \mathbb{P}^2$. Let $B$ be the branch curve of this double cover. Then $B$ is the quartic curve in $\mathbb{P}^2$ that is given by $\phi_4(x_0, x_1, x_2) = 0$.

Since the double cover $\pi$ is $\text{Aut}(X)$-equivariant, it gives a homomorphism $\text{Aut}^0(X) \rightarrow \text{Aut}^0(\mathbb{P}^2, B)$, whose kernel is either trivial or isomorphic to $\mathbb{G}_m$. Thus, the curve $B$ must be one of the quartic curves listed in the table in Proposition 6.1 except for the quartic curve consisting of four lines passing through one point, because $X$ has Du Val singularities. Now, going through the equations listed in the table in Proposition 6.1, we obtain all possibilities for the polynomial $\phi_4(x_0, x_1, x_2)$. This shows that if $\text{Aut}(X)$ is infinite, then

- either $\text{Aut}(X) \cong \mathbb{G}_a$ and $X$ is the surface $\Box$
- or $\text{Aut}(X) \cong \mathbb{G}_m$ and $X$ is one of the surfaces 5, 6, 8, 9, 10, 11, 12, 13

Vice versa, if $X$ is the surface 7 then the group $\mathbb{G}_a$ acts on $X$ as follows:

$$(x_0 : x_1 : x_2 : w) \mapsto (x_0 + tx_1 : x_1 : x_2 - 2tx_0 - t^2x_1 : w),$$

where $t \in \mathbb{G}_a$. Thus, in this case, we have $\text{Aut}(X) \cong \mathbb{G}_a$. Similarly, if $X$ is one of the del Pezzo surfaces 5, 6, 8, 9, 10, 11, 12, 13, then $X$ admits an effective action of the group $\mathbb{G}_m$, so that $\text{Aut}(X) \cong \mathbb{G}_m$ as listed in Big Table. □

7. **Cubic surfaces**

Now, we prove Main Theorem for del Pezzo surfaces of degree 3, which easily follows from [29]. Nevertheless, we prefer to give an independent proof here.

**Lemma 7.1.** **Let $X$ be a Du Val cubic surface in $\mathbb{P}^3$.**

(i) If $X$ contains three lines $L_1$, $L_2$, $L_3$ that meet each other at three distinct points (a triangle), then $X$ does not admit an effective action of the group $\mathbb{G}_a$.

(ii) If $X$ is toric, then $\rho(X) = 1$, $\#(X) = 3$, and the toric boundary is composed of three lines forming a triangle.

**Proof.** If $X$ contains a triangle and admits an effective $\mathbb{G}_a$-action, then the $\mathbb{G}_a$-action is trivial on the triangle, so that this action is trivial on the hyperplane in $\mathbb{P}^3$ that passes through the triangle, which implies that the closure of any $\mathbb{G}_a$-orbit in $X$ is contained in a line. The latter is impossible, since $X$ contains finitely many lines. This proves (i)

To prove (ii) suppose that the surface $X$ is toric. Let $D = D_1 + \cdots + D_r$ be the toric boundary. Then $r = \rho(X) + 2$. Since every line on $X$ is torus-invariant and $D \sim -K_X$, we have

$$3 = \sum_{i=1}^r (-K_X) \cdot D_i \geq r.$$
Therefore, we conclude that $\rho(X) = 1$, $r = 3$ and $-K_X \cdot D_1 = -K_X \cdot D_2 = -K_X \cdot D_3 = 1$. Moreover, the lines $D_1$, $D_2$, $D_3$ form a triangle, because the pair $(X, D)$ has log canonical singularities. □

Now, we are ready to prove

**Proposition 7.2.** Main Theorem holds for weakly minimal cubic surfaces.

**Proof.** Let $X$ be a weakly minimal Du Val cubic surface. If $\tau(X) = 1$, then Theorem 3.12 implies that $X$ is the surfaces $[19]$ and its basic properties are described in Example 3.11. In this case, the surface $X$ admits an algebraic torus action

$$(x_0, x_1, x_2, x_3) \mapsto (x_0, tx_1, t^2x_2, t^{-1}x_3)$$

Since $X$ contains three lines passing through one point, it is not toric. Since $X$ contains a triangle, it does not admit an unipotent group action by Lemma 7.1 so that $\text{Aut}^0(X) \cong \mathbb{G}_m$ as required.

Thus, to complete the proof, we may assume that $\tau(X) > 1$. By Theorem 3.8, we have only the following possibilities: $[14^\circ]$, $[15^\circ]$, $[16^\circ]$, $[18^\circ]$, $[21^\circ]$, $[22^\circ]$, $[23^\circ]$.

Consider the cases $[16^\circ]$, $[21^\circ]$, $[23^\circ]$. From the equations in Theorem 3.8, we see that $X$ contains a triangle that is cut out by $y_1y_2 = 0$. Then by Lemma 7.11, we conclude that the unipotent radical of $\text{Aut}^0(X)$ is trivial. The surface $[16^\circ]$ is a toric cubic surface because its equation is binomial, and the surfaces $[21^\circ]$ and $[23^\circ]$ are not toric by Lemma 7.11(ii). Therefore, if $X$ is the surface $[16^\circ]$ then $\text{Aut}^0(X) \cong \mathbb{G}_m^2$. Similarly, if $X$ is one of the surfaces $[21^\circ]$ or $[23^\circ]$ then we have $\text{Aut}^0(X) \cong \mathbb{G}_m$, because $X$ admits a diagonal effective action of the group $\mathbb{G}_m$.

Now, we suppose that $X$ is the surface $[18^\circ]$ Then Type$(X) = A_5$, and it follows from Theorem 3.8 that $X$ is a hypersurface in $\mathbb{P}(1, 2, 3, 3)$ that is given by

$$y_3^2 = y_1^3 + y_0^6 + y_1y_2y_3.$$ 

Let $L_1$, $L_2$, $L_3$ be the curves $y_1 = y_3^2 - y_2 = 0$, $y_2 = y_3 - y_1^3 = 0$, $y_2 = y_3 + y_3^3 = 0$, respectively. Then $L_1$, $L_2$ and $L_3$ are lines meeting at one point. If $X$ admits an effective action of the group $\mathbb{G}_m$, then $L_3$ contains a $\mathbb{G}_m$-fixed point $P \notin \text{Sing}(X)$, and there exists a $\mathbb{G}_m$-equivariant diagram

$$\begin{array}{ccc}
X & \overset{\alpha}{\longrightarrow} & \hat{X} \\
\downarrow & & \downarrow \\
Y & \overset{\beta}{\longrightarrow} & Y
\end{array}$$

where $\alpha$ is the blow up of the point $P$, the morphism $\beta$ is the birational contraction of the proper transform of the line $L_3$, and $Y$ is a singular del Pezzo surface of degree 2 such that Type$(X) = A_6$. The latter contradicts Corollary 6.2 so that $X$ does not admit an effective action of the group $\mathbb{G}_m$. Then $\text{Aut}^0(X)$ is unipotent. By Corollary 2.11, the surface $X$ does not admit an effective $\mathbb{G}_m^2$-action. Then $\dim \text{Aut}^0(X) \leq 1$. On the other hand, the group $\text{Aut}(X)$ contains the element

$$(y_1 : y_2 : y_3 : y'_3) \mapsto (y_1 : y_2 : y_3 + y_1y_2 : y'_3 + 2y_3 + y_1y_2),$$

which acts on the lines $L_1$, $L_2$ and $L_3$ as a translation. Thus, we have $\text{Aut}^0(X) \cong \mathbb{G}_a$ as required. Let $X$ be the surface $[15^\circ]$. As in the previous case, the surface $X$ is a sextic hypersurface in the weighted projective space $\mathbb{P}(1, 2, 3, 3)$. But now the surface $X$ is given by $y_3^2 = y_2^3 + y'_3y_1y_2$. Observe that the group $\text{Aut}(X)$ contains transformations

$$(y_1 : y_2 : y_3 : y'_3) \mapsto (y_1 : t^2y_2 : t^3y_3 + at^3y_1y_2 : t^4y'_3 + 2at^4y_3 + a^2t^4y_1y_2)$$

for any $a \in \mathbb{k}$ and $t \in \mathbb{k}^*$. They generate a group isomorphic to $\mathbb{B}_2$. This implies that $\text{Aut}^0(X) \cong \mathbb{B}_2$, because $X$ is not toric by Lemma 7.11(ii) and $X$ admits no effective $\mathbb{G}_m^2$-action by Corollary 2.11.

Finally, if $X$ is the surface $[14^\circ]$ then the group $\text{Aut}^0(X)$ consists of transformations

$$(y_1 : y_2 : y_3 : y'_3) \mapsto (y_1 : t^2y_2 : t^3y_3 + ay'_3 : t^6y'_3 + a^2y_3 + 2at^3y_3),$$

where $a \in \mathbb{k}$ and $t \in \mathbb{k}^*$. Thus, we have $\text{Aut}^0(X) \cong \mathbb{G}_a \times (3) \mathbb{G}_m$ (cf. Corollary B.8). □
Lemma 7.3. Let $X$ be a non-weakly minimal Du Val cubic surface such that $\text{Aut}^0(X)$ is infinite. Then $\text{Aut}^0(X) \cong \mathbb{G}_m$ and $X$ is one of the surfaces 17, 20, or 22.

Proof. The surface $X$ contains a line $L$ such that $L \subset X \setminus \text{Sing}(X)$. By Lemma 2.1(i) there is a conic bundle $\psi : X \to \mathbb{P}^1$ such that $L$ is its double section. If $X$ admits an effective $\mathbb{G}_a$-action, then the group $\mathbb{G}_a$ fixes the ramification points of the double cover $L \to \mathbb{P}^1$ induced by $\psi$, so that the group $\mathbb{G}_a$ acts trivially on $L$, which implies that it also acts trivially on the fibers of the conic bundle $\psi$, so that the $\mathbb{G}_a$-action on $X$ is trivial, which is a contradiction. Hence, we conclude that the group $\text{Aut}^0(X)$ contains no unipotent subgroups. Then $\text{Aut}^0(X)$ must be a torus, which implies that $\text{Aut}^0(X) \cong \mathbb{G}_m$, because $X$ is not toric by Lemma 7.1(ii).

Let $\psi' : X \to X'$ be the contraction of the line $L$. Then $X'$ is a quartic Du Val del Pezzo surface such that $\rho(X') = \rho(X) - 1$ and $\text{Type}(X') = \text{Type}(X')$. Note that the group $\text{Aut}(X')$ is infinite, and $\text{Aut}^0(X)$ is the stabilizer in $\text{Aut}^0(X')$ of the point $\psi'(L)$. Let $U'$ be the complement in $X'$ to the union of all lines. Then $\psi'(L) \in U'$ by Corollary 2.14.

Suppose that $\rho(X) = 2$. Then $\psi$ is an extremal contraction. By Lemma 2.12(ii), the singular points of the surface $X$ can be of types $D_4$, $D_5$, $A_3$, and $A_1$, where $A_1$ appears even number of times. We have two possibilities: $\text{Type}(X) = D_5$ and $A_2A_1$, so that $X'$ is one of the surfaces 24 or 25. In both cases, the subset $U'$ is the open $\text{Aut}^0(X')$-orbit (cf. Remark 3.4), which immediately implies that $\text{Aut}^0(X) \cong \mathbb{G}_m$ and $X$ is one of the surface 17 or 20.

Now, we assume that $\rho(X) > 2$. If $\text{Type}(X) = D_4$, then $X'$ is the surface 26. Arguing as above, we see that $\text{Aut}^0(X) \cong \mathbb{G}_m$ and $X$ is the surface 22. Thus, to complete the proof, we may assume that $\rho(X) > 2$ and all the singularities of $X$ are of type $A_n$.

We claim that the action of $\text{Aut}^0(X)$ on $L$ is trivial. Indeed, suppose that this is not the case. Let us seek for a contradiction. Let $P_1$ and $P_2$ be the ramification points of the double cover $L \to \mathbb{P}^1$, let $F_1$ and $F_2$ be the fibers of the conic bundle $\psi$ passing through the points $P_1$ and $P_2$, respectively. Then $P_1$ and $P_2$ are fixed by $\text{Aut}^0(X)$, and these are all $\text{Aut}^0(X)$-fixed points on $L$, so that all fibers of the conic bundle $\psi$ other than $F_1$ and $F_2$ are smooth. Since $\rho(X) > 2$, there exists at least one reducible fiber. Thus, we may assume that $F_1$ is reducible. Then

$$F_1 = F'_1 + F''_1,$$

where $F'_1$ and $F''_1$ are lines. Then $P_1 = F'_1 \cap F''_1 \cap L$ and the surface $X$ is smooth along $F_1$, which implies that $\text{Sing}(X) \subset F_2$ and $F_2$ is irreducible (but multiple). In particular, we have $\rho(X) = 3$. On the other hand, using Lemma 2.12(ii) we see that either $\text{Type}(X) = 2A_1$ or $\text{Type}(X) = A_3$. This contradicts the Noether formula. Therefore, the action of $\text{Aut}^0(X)$ on the line $L$ is trivial, so that the action of the group $\text{Aut}^0(X)$ on the base of the conic bundle $\psi$ is trivial as well.

Let $M'$ be a line in $X'$ (it does exist since $\rho(X') > 1$), and let $M$ be its proper transform on $X$. Then $\psi'(L) \not\subset M'$ by Corollary 2.14 so that $M$ is a line on $X$, which is disjointed from the line $L$. Then $M$ is an $\text{Aut}^0(X)$-invariant curve, which is not contained in the fibers of the conic bundle $\psi$, since $\psi$ is given by the projection from $L$. Therefore, if $C$ is a general fiber of $\psi$, then $C$ contains at least three $\text{Aut}^0(X)$-fixed points $C \cap (L \cup M)$, so that the $\text{Aut}^0(X)$-action on $C$ must be trivial. This implies that the action of $\text{Aut}^0(X)$ on $X$ is also trivial, which is a contradiction.

Combining Proposition 7.2 and Lemma 7.3, we obtain

Corollary 7.4. Main Theorem holds for del Pezzo surfaces of degree 3.

Thus Main Theorem holds for Du Val del Pezzo surface of degrees 1, 2, 3, 4, 5, 6. This follows from Proposition 5.1 and Corollaries 4.5, 5.2, 7.4. This completes the proof of Main Theorem.
8. Big Table

Let $X$ be a Du Val del Pezzo surface such that $\text{Aut}(X)$ is infinite. Then the type $\text{Type}(X)$, the degree $K_X^2$, the Picard rank $\rho(X)$, the number of lines $\#(X)$, the Fano–Weil index $\tau(X)$, the group $\text{Aut}^0(X)$, and the equation of the surface $X$ are given below. The column No indicates a del Pezzo surface from which $X$ can be obtained by blowing up a smooth point that does not lie on a line.

Appendix A. Lines and dual graphs

In this appendix, we present equations of the lines on del Pezzo surfaces that appear in Big Table. We also present the dual graphs of all the curves with negative self-intersection numbers on their minimal resolutions. As in the paper [7], we will denote a \((-1)\)-curve by \(\bullet\), and we will denote a \((-2)\)-curve by \(\circ\). We will exclude surfaces 48\textsuperscript{o}, 49\textsuperscript{o}, 50\textsuperscript{o}, 51\textsuperscript{o}, 52\textsuperscript{o}, 53\textsuperscript{o}.

Let \(X\) be a del Pezzo surface of degree \(d\) in Big Table. Take the equation of \(X\) from Big Table. The lines on \(X\) and the dual graphs of all the curves with negative self-intersection numbers on its minimal resolution can be described as follows.

1. One has \(d = 1\) and \(\text{Type}(X) = E_8\). The dual graph is

\[

(22o) One has $d = 3$ and $\text{Type}(X) = D_4$. The dual graph is

Then $X$ is not weakly-minimal. The lines on $X$ are cut by $x_0 = 0$ and $x_3 = 0$.

(23o) One has $d = 3$ and $\text{Type}(X) = 2A_2$. The dual graph is

The surface $X$ is weakly-minimal. The lines are cut out by $x_1 = 0$, $x_2 = 0$ and $x_3 = 0$.

(24o) One has $d = 4$ and $\text{Type}(X) = D_5$. The dual graph is

The surface $X$ is weakly-minimal. The line is $x_2^2 - x_1^3 = x_0 = 0$.

(25o) One has $d = 4$ and $\text{Type}(X) = A_32A_1$. The dual graph is

The surface $X$ is weakly-minimal. The lines are $x_1 = x_2 = 0$ and $x_2^2 - x_1^3 = x_0 = 0$.

(26o) One has $d = 4$ and $\text{Type}(X) = D_4$. The dual graph is

The surface $X$ is weakly-minimal, and the lines are $x_2 \pm x_1^2 = x_0 = 0$.

(27o) One has $d = 4$ and $\text{Type}(X) = A_4$. The dual graph is

Then $X$ is not weakly-minimal. The lines are cut out by $x_0 = 0$ and $x_1 = 0$.

(28o) One has $d = 4$ and $\text{Type}(X) = A_3A_1$. The dual graph is

The surface $X$ is weakly-minimal. The lines are $x_2^2 - x_1x_3 = x_0 = 0$ and $x_1 = x_2 \pm x_0^3 = 0$.

(29o) One has $d = 4$ and $\text{Type}(X) = A_22A_1$. The dual graph is

The surface $X$ is weakly-minimal. The lines are cut out by $x_2 = 0$ and $x_3 = 0$. 

29
One has $d = 4$ and Type($X$) = 4A. The dual graph is

![Graph](image)

The surface $X$ is weakly-minimal. The lines in $X$ are cut by $x_4 = 0$.

One has $d = 4$ and Type($X$) = A$_3$ and $#(X) = 4$. The dual graph is

![Graph](image)

The surface $X$ is weakly minimal. The lines are $x_2 \pm x_1^2 = x_0 = 0$ and $x_2 \pm x_0^2 = x_1 = 0$.

One has $d = 4$ and Type($X$) = A$_3$ and $#(X) = 5$. The dual graph is

![Graph](image)

Then $X$ is not weakly-minimal. The lines are cut out by $x_0 = 0$ and $x_1 = 0$.

One has $d = 4$ and Type($X$) = A$_2$A$_1$. The dual graph is

![Graph](image)

Then $X$ is not weakly-minimal. The lines are cut out by $x_1 = 0$ and $x_0 = 0$.

One has $d = 4$ and Type($X$) = 3A$_1$. The dual graph is

![Graph](image)

The surface $X$ is weakly-minimal. The lines are cut out by $x_2 = 0$ and $x_3 = 0$.

One has $d = 4$ and Type($X$) = 2A$_1$ and $#(X) = 8$. The dual graph is

![Graph](image)

The surface $X$ is weakly-minimal. The lines are cut out by $x_2 = 0$ and $x_3 = 0$.

One has $d = 5$ and Type($X$) = A$_4$. The dual graph is

![Graph](image)

The surface $X$ is weakly minimal. The line is given by $x_2^2 + x_1^4 = x_0 = 0$. 

One has \(d = 5\) and \(\text{Type}(X) = A_3\). The dual graph is

\[
\begin{array}{c}
\bullet \\
\end{array}
\begin{array}{c}
\circ \\
\circ \\
\circ \\
\circ \\
\circ \\
\bullet \\
\end{array}
\]

Then \(X\) is weakly minimal. The lines are \(x_0 = x_2 = 0\) and \(y_1 = x_2 = 0\).

One has \(d = 5\) and \(\text{Type}(X) = A_2A_1\). The dual graph is

\[
\begin{array}{c}

\bullet \\
\end{array}
\begin{array}{c}
\bullet \\
\bullet \\
\bullet \\
\bullet \\
\bullet \\
\bullet \\
\bullet \\
\end{array}
\]

Then \(X\) is not weakly minimal. The lines are cut out by \(x_0 = 0, x_1 = 0, y_0 = 0, y_1 = 0\).

One has \(d = 6\) and \(\text{Type}(X) = A_2A_1\). The dual graph is

\[
\begin{array}{c}
\bullet \\
\circ \\
\bullet \\
\bullet \\
\bullet \\
\bullet \\
\bullet \\
\end{array}
\begin{array}{c}
\bullet \\
\circ \\
\bullet \\
\bullet \\
\bullet \\
\bullet \\
\bullet \\
\end{array}
\]

Then \(X\) is weakly minimal. The line is \(x_0 = 0\).

One has \(d = 6\) and \(\text{Type}(X) = A_2\). The dual graph is

\[
\begin{array}{c}
\bullet \\
\circ \\
\bullet \\
\bullet \\
\bullet \\
\bullet \\
\bullet \\
\end{array}
\]

The surface \(X\) is weakly minimal. The lines are \(x_0 = x_1 = 0\) and \(x_0 = x_2 = 0\).
One has \( d = 6 \) and \( \text{Type}(X) = 2A_1 \). The dual graph is

\[
\begin{array}{c}
\bullet \\
\circ \\
\bullet \\
\end{array}
\]

The surface \( X \) is weakly minimal. The lines are cut out by \( x_2 = 0 \).

One has \( d = 6 \) and \( \text{Type}(X) = A_1 \). The dual graph is

\[
\begin{array}{c}
\bullet \\
\circ \\
\bullet \\
\end{array}
\]

The surface \( X \) is weakly minimal. The lines are cut out by \( x_2 = 0 \).

One has \( d = 6 \) and \( \text{Type}(X) = A_1 \) and \( \#(X) = 4 \). The dual graph is

\[
\begin{array}{c}
\bullet \\
\circ \\
\bullet \\
\end{array}
\]

The surface \( X \) is not weakly minimal. The lines are cut out by \( x_0 = 0 \).

One has \( d = 6 \) and \( X \) is smooth. The dual graph is

\[
\begin{array}{c}
\bullet \\
\circ \\
\bullet \\
\end{array}
\]

Then \( X \) is not weakly minimal. The lines are cut out by \( x_0 = 0, y_0 = 0 \) and \( z_0 = 0 \).

**Appendix B. Del Pezzo surfaces of homology type of \( \mathbb{P}^2 \)**

In this section, we recall classification of Du Val del Pezzo surfaces whose Weil divisor class group is cyclic \([23, 14, 31]\). By Lemma 2.9(iii), each such surface except \( \mathbb{P}^2 \) and \( \mathbb{P}(1, 1, 2) \) contains a unique line that generated its class group.

**Proposition B.1.** Let \( X \) be a Du Val del Pezzo surface such that \( \text{Cl}(X) \cong \mathbb{Z} \), and let \( d := K_X^2 \). Then \( d \neq 7 \). If \( d \leq 6 \), then there is an embedding \( X \hookrightarrow \mathbb{P}(1, 2, 3, d) \) such that \( X \) is given by

\[
\phi(y_1, y_2, y_3, y_d) = 0,
\]

where \( \phi \) is a homogeneous polynomial of weighted degree 6. If \( 2 \leq d \leq 6 \), then

\[
\phi = y_3^2 + y_2^3 + y_1^{6-d} y_d,
\]

so that \( X \) is uniquely determined by its degree. If \( d = 1 \), there are exactly two possibilities:

(B.2) \[
\phi = y_3^2 + y_2^3 + y_1^5 y_d,
\]

(B.3) \[
\phi = y_3^2 + y_2^3 + y_1^5 y_d + y_1^2 y_2^2,
\]

which give us two non isomorphic surfaces. The only line \( L \subset X \) is cut out by \( y_1 = 0 \).

**Proof.** The proof is similar to the proof of Theorem 3.8 \( \square \)

Thus, if \( d = 9, 8, 6 \), then \( X \cong \mathbb{P}^2, \mathbb{P}(1, 1, 2), \mathbb{P}(1, 2, 3) \), respectively.

**Remark B.4.** In the notation and assumptions of Proposition B.1, one can show that \( X \setminus L \cong A^2 \). Moreover, there is cell decomposition \( X = A^2 \cup A^1 \cup A^0 \). In particular, we have

\[
H_q(X, \mathbb{Z}) \cong H_q(\mathbb{P}^2, \mathbb{Z})
\]

for all \( q \) (cf. [3]). In the case \( d = 1 \), we can say even more: \( H^*(X, \mathbb{Z}) \cong H^*(\mathbb{P}^2, \mathbb{Z}) \) as rings.

**Remark B.5.** Suppose that \( X \) is a Du Val del Pezzo surface of degree 1 such that \( \text{Cl}(X) \cong \mathbb{Z} \).

By Proposition B.1 \( X \) is a hypersurface in \( \mathbb{P}(1, 1, 2, 3) \) that is given

(i) either by \( y_3^2 + y_2^3 + y_1^5 y'_1 = 0 \),

(ii) or by \( y_3^2 + y_2^3 + y_1^5 y'_1 + y_1^2 y_2^2 = 0 \).
These possibilities are distinguished by the collection of singular curves in the pencil $| - K_X|$. Indeed, in the first case, the pencil $| - K_X|$ contains two singular curves $y_1 = 0$ and $y'_1 = 0$, which are both cuspidal. In the second case, it has three singular curves $y_1 = 0$, $y'_1 = 0$ and $4y_1 + 27y'_1 = 0$. One of them is cuspidal, and the remaining two curves are nodal.

**Corollary B.6.** Let $X$ be a Du Val del Pezzo surface, let $d := K_X^2$. If $\text{Cl}(X) \cong \mathbb{Z}$, then Type$(X)$ is

(B.7) \[
E_8, \ E_7, \ E_6, \ D_5, \ A_4, \ A_2A_1, \ A_1, \ \varnothing \]

in the case when $d = 1, 2, 3, 4, 5, 6, 8, 9$, respectively. Vice versa, if $\rho(X) = 1$ and Type$(X)$ is one of the types (B.7), then $\text{Cl}(X) \cong \mathbb{Z}$.

**Proof.** The first assertion easily follows from Proposition [B.1] To prove the second one, we may assume that $d \leq 5$, since the remaining cases are easy. Let $\text{Cl}(X, P)$ be the local Weil divisor class group of the (unique) singular point $P \in X$. Then in the cases (B.7) we have

$\text{Cl}(X, P) \cong \mathbb{Z}/d\mathbb{Z},$

see e.g. [5, Satz 2.11]. Therefore, for any line $L \subset X$ the divisor $dL$ is Cartier. Since $dL \sim \mathbb{Q} - K_X$, we have $dL \sim -K_X$. Now, the assertion follows from Lemma 2.4[iii] and Proposition 3.4 \(\square\)

For every $d \in \{2, \ldots, 6\}$, let $X_d$ be the Du Val del Pezzo surface of degree $d$ such that $\text{Cl}(X_d) \cong \mathbb{Z}$. As we already mentioned earlier, the surface $X_d$ contains exactly one line $L_d$ and $\text{Cl}(X_d) = \mathbb{Z}[L_d]$. Take a point $P_d \in L_d \setminus \text{Sing}(X_d)$. Let $\sigma_d : \tilde{X}_d \to X_d$ be the blow up of the point $P_d$, and let $\tilde{L}_d$ be the proper transform on $\tilde{X}_d$ of the line $L_d$. Then

$$\tilde{L}_d^2 = -1 + \frac{1}{d} < 0,$$

and $K_{\tilde{X}_d}. \tilde{L}_d = 0$. Therefore, there exists a crepant contraction $\varphi_d : \tilde{X}_d \to X'_{d-1}$ of the curve $\tilde{L}_d$, where $X'_{d-1}$ is a singular Du Val del Pezzo surface such that $\text{Cl}(X'_{d-1}) \cong \mathbb{Z}$ and $K_{\tilde{X}_d}^2 = K_{X'}^2 = d - 1$. Thus, if $d \neq 2$, then $X'_{d-1} \cong X_{d-1}$ by Proposition [B.1] If $d = 2$, then $X'_1$ is one of the two surfaces described in Remark [B.5] so that we also let $X_1 = X'_1$. Hence, we obtain the following diagram:

$$
\begin{array}{cccccccc}
X_6 & \xleftarrow{\sigma_6} & \tilde{X}_6 & \xleftarrow{\varphi_6} & \tilde{X}_5 & \xleftarrow{\sigma_5} & \tilde{X}_4 & \xleftarrow{\varphi_5} & \tilde{X}_3 & \xleftarrow{\sigma_4} & \tilde{X}_2 & \xleftarrow{\varphi_4} & X_1 \\
X_5 & \xleftarrow{\sigma_5} & \tilde{X}_5 & \xleftarrow{\sigma_4} & \tilde{X}_4 & \xleftarrow{\varphi_4} & \tilde{X}_3 & \xleftarrow{\varphi_3} & \tilde{X}_2 & \xleftarrow{\varphi_3} & \tilde{X}_1 & \xleftarrow{\varphi_2} & X_1 \\
X_4 & \xleftarrow{\sigma_4} & \tilde{X}_4 & \xleftarrow{\varphi_4} & \tilde{X}_3 & \xleftarrow{\varphi_3} & \tilde{X}_2 & \xleftarrow{\varphi_2} & \tilde{X}_1 & \xleftarrow{\varphi_2} & X_1 & \\
X_3 & \xleftarrow{\sigma_3} & \tilde{X}_3 & \xleftarrow{\varphi_3} & \tilde{X}_2 & \xleftarrow{\varphi_2} & \tilde{X}_1 & \xleftarrow{\varphi_2} & X_1 & \\
X_2 & \xleftarrow{\sigma_2} & \tilde{X}_2 & \xleftarrow{\varphi_2} & \tilde{X}_1 & \xleftarrow{\varphi_2} & X_1 & \\
X_1 & \xleftarrow{\sigma_1} & \tilde{X}_1 & \xleftarrow{\varphi_1} & X_1 & \\
\end{array}
$$

It allows us to reconstruct all surfaces in Proposition [B.1] starting from $X_0 = \mathbb{P}(1, 2, 3)$.

Each birational transformation $X_{d-1} \dashrightarrow X_d$ is $\text{Aut}^0(X_{d-1})$-equivariant, so that it gives a natural embedding $\text{Aut}^0(X_{d-1}) \hookrightarrow \text{Aut}^0(X_d)$ such that $\text{Aut}^0(X_{d-1})$ is just the stabilizer of the point $P_d$. Moreover, there following two assertions hold:

- if $d \geq 3$, then $\text{Aut}^0(X_d)$ transitively acts on $L_d \setminus \text{Sing}(X_d)$;
- if $d = 2$, then $\text{Aut}^0(X_2) \cong \mathbb{G}_m$ has two orbits in $L_2 \setminus \text{Sing}(X_2)$, an open orbit and a closed orbit that consists of a single point, which explains two possibilities in Remark [B.5].

The construction also to compute $\text{Aut}^0(X)$ in the cases 10, 5, 14, 24, 36 of Big Table.

**Corollary B.8.** Let $X$ be a Du Val del Pezzo surface such that $\text{Cl}(X) \cong \mathbb{Z}$, and let $d := K_X^2$. Then the group $\text{Aut}^0(X)$ is isomorphic to

$$\mathbb{B}_3, \ \mathbb{B}_2 \times \mathbb{G}_m, \ \mathbb{G}_a \rtimes \mathbb{G}_m, \ \mathbb{G}_a \rtimes (\mathbb{G}_m)^2, \ \mathbb{G}_m$$

in the case when $d = 6, 5, 4, 3, 2$, respectively. If $d = 1$, then $\text{Aut}^0(X) \cong \mathbb{G}_m$ if $X$ is given by (B.2), and $\text{Aut}^0(X) = \{1\}$ if $X$ is given by (B.3).
