INTRODUCTION

Rett syndrome (RTT), an X-linked postnatal neurodevelopmental disorder associated with intellectual disabilities, is primarily caused by mutations in methyl-CpG-binding protein 2 (MECP2), the gene encoding MeCP2, a transcriptional modulator that binds to methylated CpG sites in promoter regions of DNA (Nan et al., 1997; Amir et al., 1999; Percy and Lane, 2005). A number of genes including brain-derived neurotrophic factor (Bdnf) were identified to be regulated by MeCP2 and relevant to the pathogenesis of RTT (Bievenu and Chelly, 2006; Chahrour and Zoghbi, 2007). MeCP2 binds to the Bdnf promoter and directly modulates Bdnf expression in an activity-dependent manner (Chen et al., 2003; Martinowich et al., 2003; Zhou et al., 2006). Several studies have reported lower BDNF mRNA and protein levels in various brain regions of Mecp2 deficient mice and RTT individuals (Chang et al., 2006; Wang et al., 2006; Ogier et al., 2007; Li et al., 2012). Reduced overall neuronal activity caused by MeCP2 deficiency is thought to contribute to BDNF downregulation. Conditional Bdnf mutant mice showed similar RTT phenotypes as Mecp2 knockout mice, while Bdnf overexpression rescued some of the functional deficits observed in Mecp2 mutants and extended their lifespan (Chang et al., 2006; Chahrour and Zoghbi, 2007). These findings strongly indicate BDNF plays a critical role in neurological dysfunctions in RTT.

Prior to RTT, BDNF had been implicated in other neurological disorders due to its widespread function in neuronal development, plasticity, differentiation, and survival (Poo, 2001; Fahnestock et al., 2002; Gines et al., 2010; Hartmann et al., 2012). Common among these BDNF-related disorders, such as Alzheimer’s disease (AD), Huntington disease (HD), is the irregular trafficking of dense-core vesicles containing BDNF, as well as activity-dependent BDNF release from those vesicles (Gauthier et al., 2004; Chapleau et al., 2009; Poon et al., 2011). Intriguingly, the single nucleotide polymorphism Val66Met observed in the human BDNF gene resulted in more severe RTT symptoms and an increased risk of seizure onset, suggesting that in addition to BDNF expression levels, BDNF trafficking and release are altered in RTT (Zeev et al., 2009; Hartmann et al., 2012). Live BDNF-YFP imaging in cultured neurons offers the ability to investigate dynamic trafficking of BDNF, which was reported to be identical to that of endogenous BDNF in terms of its cellular localization, processing and secretion (Haubensak et al., 1998; Kohara et al., 2001; Lessmann and Brigadski, 2009; Hartmann et al., 2012). Here, we report that vesicular trafficking of BDNF, as well as...
its activity-dependent release are significantly impaired in hippocampal neurons of Mecp2 knockout mice, providing further support for the role of BDNF signaling in RTT pathophysiology.

Histone deacetylase-6 (HDAC6), a member of the class II histone deacetylases, is a unique cytosolic enzyme that regulates cell motility (Hubbert et al., 2002; Matsuyama et al., 2002; Zhang et al., 2003; Tran et al., 2007), endocytosis (Gao et al., 2007), vesicle transport (Dompierre et al., 2007), cell migration and degradation of misfolded proteins (Iwata et al., 2005; Valenzuela-Fernandez et al., 2008) and other cellular process by deacetylating α-tubulin, Hsp90 and cortactin (Fukuda et al., 2012). HDAC6 has emerged as an attractive target for pharmacological intervention in several CNS diseases. Selective inhibition of HDAC6 is thought to promote neuronal survival and regrowth after injury, offering a potential therapy for various neurodegenerative diseases (Kazantsev and Thompson, 2008; Rivieccio et al., 2009; Butler et al., 2010). For example, the non-selective HDAC inhibitor trichostatin A (TSA) improves microtubule (MT)-dependent transport of BDNF-GFP in cultured neurons expressing mutant Huntingtin; this effect was ascribed to increased α-tubulin acetylation through the inhibition of cytoplasmic HDAC6 (Dompierre et al., 2007). Indeed, Tubastatin-A (TBA), a more selective HDAC6 inhibitor, showed neuroprotective effects in a model of oxidative stress, and exhibited no toxicity compared to TSA (Butler et al., 2010). Furthermore, TBA rescued the impairment of mitochondrial transport in axons and mitochondrial elongation caused by Aβ exposure (Kim et al., 2012). We report that TBA improves BDNF-YFP trafficking and activity-dependent release in Mecp2 knockout hippocampal neurons to reach wildtype levels, suggesting that HDAC6 is a potential therapeutic target to restore BDNF-dependent neuronal function in the absence of functional MeCP2, which provides a novel approach for therapeutic intervention in RTT.

MATERIALS AND METHODS

ANIMALS

Breeding pairs of mice lacking exon 3 of the X chromosome-linked Mecp2 gene (B6.Cg-Mecp2tm1Jae, “jaenisch” strain in a pure C57BL/6 background) (Chen et al., 2001) were purchased from the Mutant Mouse Regional Resource Center at the University of California, Davis. A colony was established at The University of Alabama at Birmingham (UAB) by mating wildtype males with heterozygous Mecp2tm1Jae mutant females, as recommended by the supplier. Genotyping was performed by PCR of DNA sample from tail clips. Hemizygous Mecp2tm1Jae mutant males are healthy until 5–6 weeks of age, when they exhibit RTT-like motor symptoms, such as hypoactivity, hind limb clasping, and reflex impairments (Chen et al., 2001). Animals were handled and housed according to the Committee on Laboratory Animal Resources of the National Institutes of Health. All experimental protocols were annually reviewed and approved by the Institutional Animals Care and Use Committee of UAB.

PRIMARY CULTURES OF HIPPOCAPAL NEURONS AND TRANSFECTION

Both hippocampi were dissected from anesthetized postnatal day 0 or 1 (P0–1) male Mecp2 knockout mice and wildtype littermates, and dissociated in papain (20 U/ml) plus DNase I (Worthington, Lakewood, NJ) for 20–30 min at 37°C, as described (Amaral and Pozzo-Miller, 2007). The tissue was then triturated to obtain a single-cell suspension, and the cells were plated at a density of 50,000 cells/cm² on 12 mm poly-L-lysine/aminamin coated glass coverslips, and immersed in Neurobasal medium supplemented with 2% B27 and 0.5 mM glutamine (Life Technologies, Carlsbad, CA). Neurons were grown in 37°C, 5% CO2, 90% relative humidity incubators (Thermo-Forma), with half of the fresh medium changed every 3–4 days. After 11 days in vitro (DIV), neurons were transfected with cDNA encoding BDNF-YFP (a gift from M. Kojima) using Lipofectamine 2000 (Life Technologies) (0.8 μg DNA) according to the manufacturer’s protocol.

IMMUNOCYTOCHEMISTRY

All experiments were performed at 12–14 DIV. For localization of endogenous native BDNF, neurons were fixed with 4% (wt/vol) paraformaldehyde/sucrose in phosphate buffer (PB; 23 mM NaH2PO4, 2 mM Na2HPO4 pH 7.4) for 10 min, and incubated in 0.25% (vol/vol) Triton X-100 for 10 min, then washed with PBS saline (PBS). After blocking with 10% (vol/vol) goat serum in PBS, cells were incubated with anti-BDNF antibody (2μg/g/ml, Santa Cruz Biotechnology #SC-546) overnight at 4°C, rinsed in PBS, and incubated with Alexa Fluor-488 secondary antibody (Life Technologies) for 1 h; coverslips were then mounted with Vectashield (Vector Laboratories). Images were acquired in a laser-scanning confocal microscope using a solid-state 488 nm laser for excitation, and a 60 X 1.4 NA oil immersion lens, and standard FITC dichroic and emission filters (FluoView-300, Olympus; Center Valley, PA). For dual immunocytochemistry, BDNF-YFP-expressing neurons were fixed with 3% formaldehyde in PB at 0°C for 20 min, permeabilized for 10 min at room temperature with 3% formaldehyde containing 0.25% Triton X-100, and blocked with 10% bovine serum albumin (BSA) for 1 h at 37°C. Primary goat anti-chromogranin B (1:100; Santa Cruz) and rabbit anti-BDNF (1:100, Santa Cruz) antibodies, as well as fluorescein-conjugated anti-goat and anti-rabbit secondary antibodies (Molecular Probes) were diluted in 1X PBS and 3% horse serum. Coverslips were mounted with Vectashield (Vector Laboratories), and fluorescence images were acquired with a cooled CCD camera (CoolSnap HQ2, Photometrics) on a wide-field fluorescence microscope (Eclipse TE2000-U, Nikon Instruments); BDNF-YFP was imaged with a standard FITC filter, and fluorescein-conjugated secondary antibodies with standard FITC and TRITC filters. Images were deconvolved using Metamorph (Molecular Devices).

TIME-LAPSE FLUORESCENCE IMAGING

Time-lapse imaging was performed 24–48 h after BDNF-YFP transfection. For mitochondria trafficking, neurons were incubated for 15 min with MitoTracker Red (200 nM; Life Technologies) prior to live imaging. Individual coverslips with cultured neurons were transferred to a recording chamber mounted on a fixed-stage upright microscope (Leica DM-LFS with either a 63 x 0.9 NA or a Zeiss 63 x 1.0 NA water-immersion objective), and continuously perfused (1 ml/min) with HEPES buffered artificial CSF (aCSF) at 32–34°C,
containing (mM): 119 NaCl, 5 KCl, 2 CaCl₂, 1.3 MgCl₂, 10 glucose, 10 HEPES (pH 7.4). YFP was excited with 490 ± 12 nm light using a galvanometric monochromator (Polychrome-Il, TILL Photonics; Germany), and its emission (>510 nm, FITC-LP cube) was filtered and detected with an electron-multiplying cooled CCD camera operating in frame-transfer mode (QuantEM: 512SC, Photometrics, Tucson AZ). MitoTracker Red was excited with 560 ± 12 nm and imaged through a standard TRITC cube. Digital images were acquired every 5 s (50–100 ms exposures for ∼100 × 200 pixel sub-arrays, 1 × 1 binning) for a total time of 10 min. The position of fluorescent puncta was tracked as a function of time using the Particle Tracking module of Imaris (Bitplane).

**DRUG TREATMENTS AND CELL VIABILITY ASSAYS**

BDNF-YFP-transfected neurons were treated with the HDAC6 inhibitor Tubastatin A (1 μM, prepared in 0.01% DMSO vehicle) for 48 h; 0.01% DMSO was used as control. Cell viability was assessed by trypan blue exclusion. Cells were rinsed with HBSS, and incubated with 0.4% trypan blue solution (Gibco) for 2 min at room temperature. After washing with HBSS, dead and live cells were counted in ten random fields per coverslip.

**SURFACE STAINING OF BDNF-YFP IMMUNOFLUORESCENCE**

The procedure for BDNF-YFP immuno-staining on the surface of cultured neurons was as described (Sadakata et al., 2012). Twenty-four hours after BDNF-YFP transfection, cultured neurons were stimulated with 50 mM KCl for 10 min in the absence or presence of the voltage-gated Ca²⁺ channel blocker nifedipine (50 μM), the ionotropic glutamate receptor antagonists CNQX (10 μM) and D-APV (50 μM), the GABAAR antagonist bicuculline (10 μM), or the voltage-gated Na⁺ channel blocker TTX (0.5 μM), fixed with 4% (wt/vol) paraformaldehyde/sucrose for 5 min, and then washed with PBS. After blocking with 10% (vol/vol) goat serum in PBS, cells were incubated with anti-GFP antibody (which also recognized YFP; Abcam) overnight at 4°C, rinsed in PBS, and incubated with anti-rabbit secondary antibody conjugated to Cy3 (Millipore) for 1 h; coverslips were then mounted with Vectashield medium (Vector Laboratories). Images were acquired in a laser-scanning confocal microscope using a solid-state 488 nm laser for YFP excitation, a 543 nm HeNe green laser for Cy3 excitation, a 60 × 1.4 NA oil immersion lens, and standard FITC and TRITC dichroic and emission filters (Fluoview-300, Olympus). Quantification of co-localized pixels was performed using Colocalization module in Imaris. The ratio of surface-bound BDNF-YFP to total BDNF-YFP was estimated as volumetric percentage of co-localized signals over the threshold.

**WESTERN IMMUNOBLOTTING**

For biochemical measurements of the levels of acetylated and total α-tubulin, total cell lysates were obtained by rinsing 4 × 10^5 treated hippocampal neurons with cold PBS followed by lysis in NP-40 lysis buffer (20 mM Tris at pH 8.0, 137 mM NaCl, 10% glycerol, 1% Nonidet P-40, 2 mM EDTA) containing protease inhibitor. The cell lysates were maintained with constant agitation for 30 min at 4°C and centrifuged at 12,000 g for 20 min. The supernatants were aspirated and protein concentrations were quantified by the Lowry method. Fifteen micrograms of total lysate were subjected to SDS-PAGE (Bio-Rad) and Western blot analysis with primary antibodies against acetylated α-tubulin (1:1000; Sigma) and total α-tubulin (1:2000; Life Technologies). Immunodetection was performed using Odyssey infrared imaging system (Li-Cor Bioscience).

**STATISTICAL ANALYSES**

All the experiments were performed at least 3 different times, from at least 3 different neuronal culture preparations. Data are presented as mean ± standard error of the mean (SEM), and were compared using unpaired Student’s t-test for two groups or One Way ANOVA with Tukey post test for more than three groups; percentages were compared using Chi-square test. All analyses were performed using Prism software (GraphPad Software, San Diego, CA). P < 0.05 was considered significant.

**RESULTS**

**BDNF-YFP TRAFFICKING IS IMPAIRED IN MECP2 KNOCKOUT NEURONS**

The cellular localization, processing and secretion of exogenously expressed BDNF-xFP have been reported to be identical to those of endogenous native BDNF, including its co-localization to secretory granule cargoes like chromogranin-B and SGA2 (Haubensak et al., 1998; Kohara et al., 2001; Lessmann and Brigadski, 2009; Hartmann et al., 2012) (Supplemental Figure 1). To evaluate whether the dynamics of dendritic BDNF trafficking is altered by Mecp2 deletion, time-lapse fluorescence imaging of BDNF-YFP was performed in primary cultures of hippocampal neurons (12–14 days in vitro, DIV) from male Mecp2 knockouts and wildtype littersmates. BDNF-YFP puncta are widely distributed and move bi-directionally in live neurons (Figures 1A,B), as previously described (Park et al., 2008; Matsuda et al., 2009). The average velocity of BDNF-YFP puncta was significantly slower in Mecp2 knockout neurons (0.10 ± 0.01 μm/s, n = 261 puncta from 8 cells) compared to wildtype cells (WT 0.25 ± 0.01 μm/s, n = 225 puncta from 8 cells; p < 0.001). Analyses of the distributions of the velocity of BDNF-YFP puncta revealed that the number of fast moving puncta (velocity >0.4 μm/s) is significantly smaller in Mecp2 knockout neurons (Mecp2 1.30 % vs. WT 16.77 %; p < 0.001; Figures 1C,D). To quantify BDNF transport efficiency, we compared the persistence of each BDNF-YFP puncta, estimated as the ratio of total distance traveled during an image sequence over the minimum displacement between image frames (Gauthier et al., 2004). Consistent with impaired and slower BDNF trafficking, the persistence of BDNF-YFP puncta was higher in Mecp2 knockout neurons (Mecp2 7.14 ± 0.98 vs. WT 3.91 ± 0.43; p < 0.05; Figure 1E). Then, we tested whether the transport of other organelles such as mitochondria is also affected by Mecp2 deletion. Intriguingly, time-lapse imaging of MitoTracker-Red puncta revealed a lower percentage of fast moving mitochondria in Mecp2 knockout neurons (Mecp2 6.08 % vs. WT 12.39 %; p < 0.01; Figure 1F), but no significant differences in their average velocity or persistence between Mecp2 knockout (n = 410 puncta from 13 cells) and wildtype neurons (n = 359 puncta from 14 cells; p > 0.05; Figures 1G,H).
FIGURE 1 | BDNF-YFP trafficking is impaired in MeCP2 knockout neurons. (A) Representative example of a cultured pyramidal neuron expressing BDNF-YFP; scale bar = 10 μm. The white square is enlarged in (B). (B) Movement of BDNF-YFP puncta (a, b, and c); scale bar = 5 μm. Each image was taken at the time point indicated at bottom left. (C) Distributions of velocities of BDNF-YFP puncta in wildtype and MeCP2 knockout neurons. (D) Cumulative frequency of velocities of BDNF-YFP puncta from the histograms shown in (C). (E) Cumulative frequency of persistence of BDNF-YFP puncta. (F) Distributions of velocities of MitoTracker-Red puncta in wildtype and MeCP2 knockout neurons. (G) Cumulative frequency of velocities of MitoTracker-Red puncta from the histograms shown in (F). (H) Cumulative frequency of persistence of MitoTracker-Red puncta.

THE IMPAIRMENT OF BDNF-YFP TRAFFICKING IN MECP2 KNOCKOUT NEURONS IS BI-DIRECTIONAL

Anterograde BDNF transport from somata to dendrites and axon terminals is important for activity-dependent BDNF release to participate in synaptic plasticity, while retrograde BDNF transport back to the soma is critical for neurotrophin recycling and nuclear signaling (Egan et al., 2003; Park et al., 2008). When BDNF-YFP puncta were separated by their trafficking direction, MeCP2 knockout neurons showed significantly fewer BDNF puncta moving in both anterograde and retrograde directions than wildtype neurons, with a significantly shorter total distance traveled in either direction in MeCP2 knockout cells (p < 0.001; Figures 2A,B). Consistently, the average velocity of BDNF-YFP puncta moving in both anterograde and retrograde directions was significantly slower (p < 0.001; Figure 2C), and their persistence higher (p < 0.05 in retrograde direction; Figure 2D), in MeCP2 knockout neurons.

THE HDAC6-SELECTIVE INHIBITOR TBA IMPROVES BI-DIRECTIONAL BDNF-YFP TRAFFICKING IN MECP2 KNOCKOUT NEURONS

HDAC6 removes acetyl groups from α-tubulin (Hubbert et al., 2002; Matsuyama et al., 2002; Zhang et al., 2003), which makes microtubules less stable. Since BDNF is transported along microtubules (Gauthier et al., 2004), inhibiting HDAC6 is expected to improve BDNF trafficking by stabilizing microtubules (Dompiere et al., 2007). We tested whether treatment with the selective HDAC6 inhibitor enhances BDNF-YFP trafficking in cultured hippocampal neurons. Treatment with Tubastatin A for 48 h (TBA, 1 μM, prepared in 0.01% DMSO) was not neurotoxic, as determined by trypan blue exclusion (p > 0.05;
Supplemental Figure 2A). Then, we confirmed that TBA affected the acetylation state of α-tubulin under our experimental conditions. Western immunoblots of cultured hippocampal neurons (DIV12) treated with TBA showed that the levels of acetylated tubulin were significantly increased in wildtype neurons ($p < 0.01$; Supplemental Figure 2B), and elevated by two times in Mecp2 knockout neurons ($p < 0.001$; Supplemental Figure 2B).

Next, we tested the effect of HDAC6 inhibition on BDNF-YFP trafficking. Compared to vehicle-treated neurons (162 puncta from 7 cells), TBA increased the proportion of retrogradely moving BDNF puncta (159 puncta from 7 cells; $p < 0.01$; Figure 3A), as well as the average velocity of puncta moving anterogradely and retrogradely in Mecp2 knockout neurons ($p < 0.001$; Figure 3B). However, TBA did not affect the persistence of BDNF puncta in Mecp2 knockout neurons ($p > 0.05$; Figure 3C). On the other hand, TBA had no effect in any of these BDNF-YFP trafficking parameters in wildtype neurons (DMSO 106 puncta from 5 cells; TBA 149 puncta from 7 cells; $p > 0.05$; Figures 3A–C).

ACTIVITY-DEPENDENT BDNF RELEASE WAS IMPAIRED IN MECP2 KNOCKOUT NEURONS, AND IMPROVED BY INHIBITING HDAC6

Improving BDNF transport to release sites could in principle also enhance its activity-dependent release. To estimate activity-dependent BDNF secretion, BDNF-YFP-expressing neurons were depolarized with 50 mM KCl, followed by immunostaining with anti-YFP antibody before cell permeabilization. The degree of co-localization between immunopositive puncta (labeled with red-conjugated anti-YFP secondary antibody), and native YFP fluorescent puncta after fixation is directly proportional to BDNF-YFP secreted during neuronal depolarization (Figure 4A), as described (Sadakata et al., 2012). KCl-induced postsynaptic secretion of BDNF depends on Ca^{2+} influx (Hartmann et al., 2001; Kolarow et al., 2007), mainly through L-type voltage-gated Ca^{2+} channels (Wang et al., 2002). Here, we confirmed that elevated KCl-induced BDNF secretion was absent in a Ca^{2+} free solution ($n = 18$ cells), or in the presence of the L-type Ca^{2+} channel blocker nifedipine (50 μM; $n = 16$; $p < 0.05$; Figure 4B). Ca^{2+} channels can also be activated by depolarization from GABA<sub>A</sub> receptor activity in immature neurons with high intracellular Cl<sup>−</sup> concentration (Fiorentino et al., 2009; Porcher et al., 2011). Indeed, the GABA<sub>A</sub> receptor antagonist bicuculline also prevented KCl-induced BDNF secretion (10 μM; $n = 15$; $p < 0.05$; Figure 4B). In addition, KCl-induced BDNF secretion required functional ionotropic glutamate receptor activity (10 μM CNQX, 50 μM D-APV; $n = 17$; $p < 0.01$), and voltage-sensitive Na<sup>+</sup> channels (0.5 μM TTX; $n = 19$; $p < 0.05$; Figure 4B), as previously described (Lessmann et al., 2003). Figure 5 illustrates the different mechanisms leading to Ca^{2+}-dependent BDNF release during KCl-induced depolarization. Consistent with reports of impaired activity-dependent BDNF release using different assays (Li et al., 2012), the
How did HDAC6 inhibition produce these effects? It is known that acetylation of $\alpha$-tubulin at Lys-40 promotes axonal transport of amyloid precursor protein (App) without affecting its mRNA and protein levels (Roux et al., 2012). Also, we showed here that MeCP2 knockout neurons have fewer fast-moving mitochondria than wildtype neurons, suggesting that MeCP2 deficiency affects microtubule-dependent transport in general. Whether and how the molecular motors responsible for anterograde (kinesin-1), and retrograde transport (dynein/dynactin) are affected in RTT needs to be further explored.

We showed that the selective HDAC6 inhibitor TBA improves BDNF trafficking in MeCP2 knockout neurons by increasing the proportion of moving BDNF puncta and their average velocity in both anterograde and retrograde directions. TBA also restored activity-dependent BDNF release in MeCP2 knockout neurons to levels comparable to those of wildtype neurons. How did HDAC6 inhibition produce these effects? It is known that acetylation of $\alpha$-tubulin at Lys-40 promotes axonal transport of cargo proteins by increasing microtubule stability (Reed et al., 2006; Bulinski, 2007), and that inhibition of HDAC6 is responsible for such increased $\alpha$-tubulin acetylation that leads to enhanced axonal transport of lysosomes and other secretory vesicles (Dompierre et al., 2007). Consistently, in vivo treatment with TBA improves axonal trafficking in a mouse model of Charcot-Marie-Tooth disease by increasing $\alpha$-tubulin acetylation and enhancing microtubule rigidity (d’Yde, 2011).
Activity-dependent release of BDNF-YFP is impaired in Mecp2 knockout neurons. (A) Representative examples of BDNF release in wildtype and Mecp2 knockout neurons: no treatment, stimulated with KCl, stimulated with KCl in the absence of extracellular Ca\(^{2+}\) and stimulated with KCl upon TBA treatment; scale bar = 10 \(\mu\)m. BDNF-YFP is shown in green, while YFP immunoreactivity is shown in red. Yellow pixels represent colocalization of green and red pixels, i.e., secreted BDNF. (B) Proportion of released BDNF per total BDNF upon KCl stimulation in wildtype neurons and Mecp2 knockout neurons in the absence or presence of extracellular Ca\(^{2+}\), nifedipine (50 \(\mu\)M), CNQX (10 \(\mu\)M) /D-APV (50 \(\mu\)M), Bicuculline (10 \(\mu\)M), TTX (0.5 \(\mu\)M) or TBA (1 \(\mu\)M). The proportion of released BDNF per total BDNF was normalized to that in non-stimulated neurons (Ctl), and expressed as % of Ctl. *\(p<0.01\); wildtype vs. Mecp2 knockout; **\(p<0.01\) compared to Mecp2 knockout Ctl group stimulated with KCl; \#\(p<0.05\); ##\(p<0.01\) compared to wildtype Ctl group stimulated with KCl.

Therefore, HDAC6 inhibitors represent a potential therapeutic strategy for neurodegenerative disorders in which microtubule-dependent intracellular transport is impaired (Dompierre et al., 2007; Kim et al., 2012). Our results also showed that TBA increased \(\alpha\)-tubulin acetylation in wildtype neurons, but not as much as in Mecp2 knockout neurons. However, we didn’t find any effect of TBA in wildtype neurons. This might be because BDNF trafficking is in the optimal state in wildtype neurons. TBA restored impaired BDNF trafficking in Mecp2 knockout neurons to wildtype levels.

In the present study with BDNF-YFP transfected in hippocampal neurons, we cannot exclude an artifact of BDNF overexpression to endogenous levels. However, the intracellular localization of BDNF-YFP is similar to that of endogenous BDNF, including its co-localization to secretory granule cargoes like chromogranin-B and SGA2 (Haubensak et al., 1998; Kohara et al., 2001; Lessmann and Brigadski, 2009; Hartmann et al., 2012) (Supplemental Figure 1), suggesting that the trafficking properties of BDNF-YFP can be comparable to those of endogenous BDNF. Even though BDNF expression is higher, we cannot ignore the differences of BDNF trafficking and release between wildtype and Mecp2 knockout neurons.

In conclusion, our findings revealed that bi-directional trafficking of BDNF and its activity-dependent release are significantly impaired in hippocampal neurons of Mecp2 knockout mice, and that this deficit can be improved by enhancing tubulin acetylation with a selective HDAC6 inhibitor, which should improve microtubule-based transport. Targeting molecular components responsible for microtubule-based trafficking of BDNF-containing dense core vesicles is a potential strategy to reverse cellular and synaptic impairments in RTT.
