Abstract

Butyricimonas phoceensis strain AT9 (= CSUR P2478 = DSM 100838) was isolated from the faeces of a 57-year-old French woman living in Marseille using the culturomics approach. The genome of this Gram-negative-staining, anaerobic and non–spore forming rod bacillus is 4 736 949 bp long and contains 3947 protein-coding genes. Genomic analysis identified 173 genes as ORFans (4.5%) and 1650 orthologous proteins (42%) not shared with the closest phylogenetic species, Butyricimonas virosa. Its major fatty acid was the branched acid iso-C15:0 (62.3%).

Introduction

Butyricimonas phoceensis strain AT9 (= CSUR P2478 = DSM 100838) was isolated from the faeces of a 57-year-old French woman living in Marseille with class III morbid obesity (body mass index (BMI) 55.8 kg/m²). This isolate is part of an exploratory study of the gut flora from obese patients before and after bariatric surgery. Bariatric surgery is the most effective treatment for morbid obesity for sustainable weight loss and leads to an enrichment of the gut flora [1]. The goal of our study was to compare microbial diversity of the gut flora in obese patients before and after bariatric surgery by culturomics. The aim of culturomics is to exhaustively explore the microbial ecosystem of gut flora by using different culture conditions followed by matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS) identification [2].

The conventional approaches used in the delineation of bacterial species are 16S rRNA sequence identity and phylogeny [3], genomic (G+C content) diversity and DNA-DNA hybridization (DDH) [4,5]. However, these approaches present some difficulties, mainly as a result of their cutoff values, which change according to species or genera [6]. The accession of new technology tools, such as high-throughput sequencing, has made available nucleotide sequence libraries for many bacterial species [7]. We recently suggested incorporating genomic data in a polyphasic taxonogenomics approach to describe new bacteria. This procedure considers phenotypic characteristics, genomic analysis and the MALDI-TOF MS spectrum comparison [8,9].

Here we propose a classification and a set of characteristics for Butyricimonas phoceensis strain AT9, together with the description of complete genome sequencing, annotation and comparison as new species belonging to the genus Butyricimonas. The genus Butyricimonas was established in 2009 by

Sakamoto and encompasses four described species (B. faecihominis, B. synergistica, B. paravirosa and B. virosa). They were isolated from rat or human faeces and belong to the family Porphyromonadaceae [10,11]. The family Porphyromonadaceae contains 11 genera: Porphyromonas (type genus), Barnesiella, Butyririmonas, Dysgonomonas, Macellibacteroides, Odoribacter, Paludibacter, Parabacteroides, Petrimonas, Proteiniphilum and Tannerella [12]. Butyririmonas virosa bacteraemia has been described in patients with colon cancer [13,14] and in patients with posttraumatic chronic bone and joint infection [14].

Materials and Methods

Sample collection
A stool sample was collected from a 57-year-old obese French woman (BMI 55.8 kg/m²; 150 kg, 1.64 m tall) in June 2012. Written informed consent was obtained from the patient at the nutrition, metabolic disease and endocrinology service at La Timone Hospital (Marseille, France). The study and assent procedure were approved by the local ethics committee (IFR 48, no. 09-022, 2010). The stool sample was stored at −80°C after collection.

Isolation and identification of strain
Strain isolation was performed in May 2015. Stool extract was preincubated in blood culture bottles enriched with lamb rumen juice and sheep’s blood in anaerobic atmosphere as described elsewhere [2]. The culture was followed closely for 30 days. At different time points (days 1, 3, 7, 10, 15, 21 and 30), a seeding of the preincubated product was performed on sheep’s blood in anaerobic atmosphere as described elsewhere [2]. The culture was followed closely for 30 days. At different time points (days 1, 3, 7, 10, 15, 21 and 30), a seeding of the preincubated product was performed on sheep’s blood–enriched Columbia agar (bioMérieux, Marcy l’Etoile, France) during 48 hours of incubation in an anaerobic atmosphere at 37°C. Colonies that emerged were cultivated in the same isolated conditions.

The colonies were then identified by MALDI-TOF MS as previously described [15]. Briefly, one isolated bacterial colony was picked up with a pipette tip from a culture agar plate and spread as a thin smear on a MTP 384 MALDI-TOF MS target plate (Bruker Daltonics, Leipzig, Germany). Measurement and identification were performed as previously described [16]. When a bacterium was unidentifiable, 16S rRNA gene amplification and sequencing were performed.

The 16S rRNA PCR coupled with sequencing were performed using GeneAmp PCR System 2720 thermal cyclers (Applied Biosystems, Bedford, MA, USA) and ABI Prism 3130xl Genetic Analyzer capillary sequencer (Applied Biosystems) respectively [17]. Chromas Pro 1.34 software (Technelysium, Tewantin, Australia) was used to correct sequences, and BLASTn searches were performed at the National Center for Biotechnology Information (NCBI) website (http://blast.ncbi.nlm.nih.gov/blast.cgi).

Phylogenetic analysis
A custom Python script was used to automatically retrieve all species from the same family of the new species and download 165 sequences from NCBI by parsing NCBI results and NCBI taxonomy page. The scripts also remove species that are not found on the List of Prokaryotic Names With Standing in Nomenclature (LPSN) website (http://www.bacterio.net/). The script retains the most appropriate 16S sequence (the longest sequence with the smallest number of degenerate nucleotides) whilst also retaining one sequence from another genus as an outside group. It then aligns and trims the extremities of the sequences. Sequences were aligned using Muscle v3.8.31 with default parameters, and phylogenetic inferences were obtained using neighbour-joining method with 500 bootstrap replicates within MEGA6 software.

Phenotypic and biochemical characterization
Growth conditions. Different growth temperatures (28, 37, 45 and 55°C) were tested on sheep’s blood–enriched Columbia agar (bioMérieux). Growth of this strain was tested under anaerobic conditions using the GENbag anaer system (bioMérieux), microaerophilic conditions using the GENbag microaer system (bioMérieux) and under aerobic conditions with or without 5% CO₂. The tolerance to salt of this strain over a range salt concentrations (0–100 g/L) on Schaedler agar with 5% sheep’s blood (bioMérieux) under anaerobic atmosphere was performed.

Microscopy. A heat shock at 80°C for 20 minutes was performed for the sporulation test. A fresh colony was observed between blades and slits using a photonic microscope Leica DM 1000 (Leica Microsystems, Nanterre, France) at 40× to assess the motility of the bacteria. Gram staining was performed and observed using a photonic microscope Leica DM 2500 with a 100× oil-immersion objective lens. Transmission electron microscopy using a Tecnai G20 device (FEI Company, Limeil-Brevannes, France) at an operating voltage of 60 kV was performed to observe strain AT9 after negative colouration.

Biochemical assays. Biochemical assays were performed using API Gallery systems (API ZYM, API 20A and API 50CH) according to the manufacturer’s instructions (bioMérieux). Detection of catalase (bioMérieux) and oxidase (Becton Dickinson, Le Pont de Claux, France) was also performed according to the manufacturer’s instructions.

Antibiotic susceptibility. The antibiotic susceptibility of the strain was tested using a disk diffusion method [18] for 21 antibiotics...
including the following: amoxicillin 25 μg/mL, amoxicillin–clavulanic acid 30 μg/mL, ceftriaxone 30 μg, ciprofloxacin 5 μg, clindamycin (DA15), colistin (CT50), Dalacin 15 μg/mL, doripenem 10 μg/mL, doxycycline 30 IU, erythromycin 15 IU, fosfomycin 10 μg, gentamicin 500 μg, gentamicin 15 μg, imipenem 10 μg/mL, metronidazole 4 μg/mL, oxacillin 5 μg, penicillin G 10 IU, rifampicin 30 μg, sulfamethoxazole 23.75 μg, trimethoprim 1.25 μg, teicoplanin (TEC30) and vancomycin 30 μg ([2], Montpellier, France). The 1200 scan was used for the interpretation of results (Interscience, Saint-Nom-La-Bretèche, France).

Fatty acid analysis. Fresh colonies from a plate of Columbia agar with 5% sheep’s blood were collected after 48 hours’ incubation at 37°C for fatty acid analysis. Cellular fatty acid analysis was performed by gas chromatography/mass spectrometry (GC/MS). Two samples were prepared with approximately 100 mg of bacterial biomass each collected from a culture plate. Cellular fatty acid methyl esters were prepared as described by Sasser [19]. GC/MS analyses were carried out as previously described [20]. Briefly, fatty acid methyl esters were separated using an Elite S-MS column and monitored by a Clarus 500 gas chromatograph equipped with a SQBS MS detector (PerkinElmer, Courtaboeuf, France). Fatty acid methyl esters were identified by using the spectral database search using MS Search 2.0 operated with the Standard Reference Database 1A (National Institute of Standards and Technology, Gaithersburg, MD, USA) and the FAMES mass spectral database (Wiley, Chester, UK).

Genome sequencing and assembly
Genomic DNA (gDNA) of strain AT9 was sequenced using MiSeq Technology (Illumina, San Diego, CA, USA) with the mate-pair strategy. The gDNA was barcoded so it could be mixed with 11 other projects with the Nextera Mate Pair sample prep kit (Illumina). The gDNA was quantified by a Qubit assay with the high-sensitivity kit (Thermo Fisher Scientific Life Sciences, Waltham, MA, USA) to 325 ng/μL. The mate-pair library was prepared with 1.5 μg of genomic DNA using the Nextera mate pair Illumina guide. The genomic DNA sample was simultaneously fragmented and tagged with a mate-pair junction adapter. The pattern of the fragmentation was validated on an Agilent 2100 BioAnalyzer (Agilent Technologies, Santa Clara, CA, USA) with a DNA 7500 lab chip. The DNA fragments ranged in size from 1.5 to 11 kb with an optimal size at 4.8 kb. No size selection was performed, and 600 ng of fragmented fragments were circularized. The circularized DNA was mechanically sheared to small fragments with an optimal at 966 bp on the Covaris S2 device in T6 tubes (Covaris, Woburn, MA, USA). The library profile was visualized on a High Sensitivity Bioanalyzer LabChip (Agilent Technologies), and the final concentration library was measured at 24.3 nmol/L. The libraries were normalized at 2 nM and pooled. After a denaturation step and dilution at 15 μL, the pool of libraries was loaded onto the reagent cartridge and then onto the instrument along with the flow cell. Automated cluster generation and sequencing run were performed in a single 39-hour run at a 2 × 151 bp read length. Total information of 8.9 Gb was obtained from a 1009K/mm² cluster density, with a cluster passing quality control filters of 91.5% (17 486 000 passing filter-paired reads). Within this run, the index representation for strain AT9 was determined to be 8.38%. The 1 465 998 paired reads were trimmed then assembled in six scaffolds using Spades software [21].

Genome annotation and comparison
Open reading frames (ORFs) were predicted using Prodigal [22] with default parameters. Nevertheless, the predicted ORFs were excluded if they spanned a sequencing gap region (contains N). The predicted bacterial protein sequences were searched against the GenBank and Clusters of Orthologous Groups (COGs) databases using BLASTP (E value 1e-03 coverage). If no hit was found, it searched against the nr (nonredundant) database using BLASTP with an E value of 1e-03, coverage 70% and identity 30%. If the sequence length was smaller than 80 amino acids, we used an E value of 1e-05. The tRNAs and rRNAs were predicted using the tRNA Scan-SE and RNAmmer tools respectively [23,24]. Phobius was used to foresee the signal peptides and number of transmembrane helices respectively [25]. Mobile genetic elements were foretold using PHAST and RAST [26,27]. ORFans were identified if none of the BLASTP runs provided positive results (E value lower than 1e-03 for an alignment length greater than 80 amino acids. If alignment lengths were smaller than 80 amino acids, we used an E value of 1e-05). Artemis and DNA Plotter were used for data management and visualization of genomic features respectively [28,29]. Genomes were automatically retrieved from the 16S rRNA tree using Xegen software (PhyloPattern) [30]. For each selected genome, complete genome sequence, proteome genome sequence and Orfeome genome sequence were retrieved from the NCBI FTP site. All proteomes were analysed with proteinOrtho [31]. Then for each couple of genomes, a similarity score was computed. This score is the mean value of nucleotide similarity between all couple of orthologous genes between the two genomes studied (average genomic identity of orthologous gene sequences (AGIOS)) [7]. For the genomic comparison of strain AT9, we used Butyrivimonas virosa (type) strain JCM15149T (Genbank project number: JAEW00000000), Odoribacter laneus strain YT12061 (ADMC00000000), Bacteroides plebeius strain DSM17135

(ABQC00000000), Paraprevotella clara strain YIT11840 (AFFY00000000), Parabacteroides merdae ATCC43184 (AAXE00000000), Porphyromonas catoniae ATCC 51270 (JDF00000000) and Odoribacter splanchnicus strain DSM20712 (CP002544). An annotation of the entire proteome was performed to define the distribution of functional classes of predicted genes according to the clusters of orthologous groups of proteins (using the same method as for the genome annotation). The genome of strain AT9 was locally aligned pairwise using the BLAT algorithm [28,29] against each of the selected genomes previously cited, and DDH values were estimated from a generalized model [32]. Annotation and comparison processes were performed in the multiagent software system DAGOBAH [33], which includes Figenix [34] libraries that provide pipeline analysis.

Results

Phylogenetic analysis
The spectrum generated from clean strain AT9 spots did not match with those identified from the Bruker database even when two strains of Butyricimonas virosa, including the type strain (JCM15149T), were included in the database (Fig. 1a). The phylogenetic analysis, performed using 16S rRNA gene sequences, showed that our strain AT9 exhibited 98.3, 97.8, 97.5 and 94.2% similarity with Butyricimonas virosa JCM 15149T, Butyricimonas faecihominis JCM 18676T, Butyricimonas paravirosa JCM 18677T and Butyricimonas synergistica JCM 15148T respectively [9,10] (Table 1). However, this percentage remains lower than the 98.7% 16S rRNA gene sequence threshold recommended by Kim et al. [35] to delineate a new species. The neighbour-joining phylogenetic tree (Fig. 2), based on 16S rRNA gene sequences, shows the relationships between strain AT9 and some related taxa. The 16S rRNA sequence of strain AT9 was deposited in European Molecular Biology Laboratory—European Bioinformatics Institute (EMBL-EBI) under accession number LN881597. A gel view was performed in order to see the spectra differences of strain AT9 with other related bacteria. Eleven discordant peaks were found when we compared strain AT9 and the B. virosa JCM15149T profile (Fig. 1b).

Phenotypic and biochemical characterization
The growth of strain AT9 occurred between 28 to 37°C, but optimal growth was observed at 37°C after 48 hours' incubation in anaerobic atmosphere. It is an anaerobic bacillus, but it

can also grow in microaerophilic atmospheres at 28°C. The colonies were ~1 to 2 mm in diameter and opalescent on 5% sheep’s blood–enriched Columbia agar. Growth of this isolate was observed using 5 g of salt on Schaedler agar with 5% sheep’s blood but not with 10 g/L of salt. This bacterium is not able to form spores. It is a Gram-negative stain (Fig. 3a); it is a motile rod-shaped bacterium that is catalase positive and oxidase negative. Cell diameter ranges 0.5 to 1.5 μm, with a mean diameter of 1 μm by electron microscopy (Fig. 3b). Table 2 summarizes the classification and main features of strain AT9.

Using the API ZYM strip, we observed that strain AT9 possesses alkaline phosphatase, esterase (C4), esterase lipase (C8), naphthol-AS-BI-phosphohydrolase, phosphatase acid and N-acetyl-β-glucosaminidase activities; there were no activities for the other enzymes tested. Using API 20A strip, positive reactions were obtained for indole, D-glucose, D-lactose, glycerol and D-mannose. Using the API 50 CH strip, positive reactions were observed only with esculin ferric citrate and potassium 2-ketogluconate. The differences of characteristics compared to other representatives of the genus Butyricimonas are detailed in Table 3.

Of the 21 antibiotics tested, strain AT9 was susceptible to gentamicin 500 μg, vancomycin, doxycycline, trimethoprim–sulfamethoxazole, rifampicin, amoxicillin 25 μg/mL, metronidazole 4 μg/mL, amoxicillin–clavulanic acid 30 μg/mL, imipenem 10 μg/mL, penicillin G, teicoplanin and doripenem 10 μg/mL and was resistant to erythromycin, oxacillin, gentamicin 15 μg, colistin, ceftriaxone, ciprofloxacin, clindamycin, dalacin 15 μg/mL and fosfomycin. Analysis of the total cellular fatty acid composition demonstrated that the major fatty acid detected was the branched iso-C15:0 acid (62.3%). Hydroxy and cyclo fatty acids were also detected (Table 4).

**Genome properties**

The draft genome of strain AT9 (Fig. 4) (accession no. FBYB00000000) is 4 736 949 bp long with 42.51% G+C content (Table 5). It is composed of six scaffolds comprising seven contigs. Of the 4007 predicted genes, 3947 were protein-coding genes and 60 were RNAs (four genes 5S rRNA, one 16S rRNA, one 23S rRNA and 54 tRNA). A total of 2386 genes (60.45%) were assigned as putative functions (by COGs or by NR BLAST), 178 genes (4.51%) were identified as ORFans and ten genes were associated with polyketide synthase or non-ribosomal peptide synthetase [36]. Using ARG-ANNOT [37], three genes associated with resistance were found, including TetQ, TetX (which confers resistance to tetracycline) and ErmF (which confers resistance to erythromycin). This could represent the in silico/in vitro discordance for antibiotic resistance prediction, as strain AT9 was resistant to erythromycin but susceptible to doxycycline. The remaining 1316 genes (33.34%) were annotated as hypothetical proteins. Genome statistics are provided in Table 5. Table 6 lists the distribution of genes into COGs functional categories of strain AT9.
**Genome comparison**

The draft genome (4.74 Mb) sequence of strain AT9 is smaller than those of *Butyricimonas synergistica* (4.77 Mb), but larger than those of *Butyricimonas virosa, Porphyromonas catoniae, Bacteroides plebeius, Paraprevotella clara, Butyricimonas syngentica and Porphyromonas catoniae* (4.65, 4.34, 4.43, 4.48, 45.3, 48.1, 46.4 and 51.0% respectively) but larger than those of *Odoribacter laneus* (40.55). Fig. 5 shows that the distribution of genes into COGs categories was similar in all genomes compared. In addition, strain AT9 shared 2297, 1535, 742, 1720, 999, 1173, 2108 and 960 orthologous genes with *B. virosa, O. laneus, P. catoniae, O. splanchnicus, B. plebeius, P. merdae, B. syngentica and P. clara* respectively (Table 6). Accordingly, strain AT9 has 1650 (42%) of 3947 orthologous proteins not shared with its closest phylogenetic neighbour, *B. virosa*. The AGIOS values ranged from 53.3 to 76.2% among the compared closest species except strain AT9. When strain AT9 was compared to other close species, the AGIOS values ranged from 53.5% with *P. catoniae* to 97.7% with *B. virosa* (Table 7).

**TABLE 3. Differential characteristics of strain Butyricimonas phoceensis strain AT9 with Butyricimonas species**

| Property                          | Strain AT9 | B. virosa | B. faecihominis | B. paravirosa | B. synergistica |

Number are percentages. NA, not available; TR, trace amounts <1%.
The DDH value was 80.2% ± 2.7 with *B. virosa*, 17.7% ± 2.2 with *O. laneus*, 21.4% ± 2.3 with *B. plebeius*, 20.2% ± 2.3 with *P. clara*, 19.1% ± 2.2 with *P. merdae*, 18.3% ± 2.2 with *P. catoniae* and 17.3% ± 2.2 with *O. splanchnicus* (Table 8).

**Discussion**

Strain AT9 is part of an exploratory culturomics study of the gut flora from obese patients before and after bariatric surgery. The aim of culturomics is to exhaustively explore the microbial ecosystem of gut flora by using different culture conditions followed by MALDI-TOF MS identification [2]. The phylogenetic analysis, performed using 16S rRNA sequences, showed that strain AT9 exhibited 98.3% similarity with *Butyricimonas virosa*. However, this percentage remains lower than the 98.7% 16S rRNA gene sequence threshold recommended to delineate a new species [3,38].

The genus *Butyricimonas* was established in 2009 by Sakamoto and includes four described species [9–11]. All the species of the genus *Butyricimonas* are anaerobic. These bacteria are isolated in human or rat faeces. To evaluate the genomic similarity with other closest species, we determined two parameters: DDH [39] and AGIOS [7]. Although the values of DDH (80.2%) and AGIOS (97.7%) were very high between strain AT9 and *Butyricimonas virosa* (type strain JCM15149T), we found several discrepancies justifying the description of a new species, including motility, D-mannose utilization (absent in...
B. virosa but present in B. paravirosa, B. synergistica and B. faecihominis), MALDI-TOF MS spectrum (11 different peaks), different GC% (42.5 vs. 46.5% for B. virosa), high proportion of orthologous proteins not shared between the two species (1650/3947 (42%)) and different COGs repartition ((D) cell cycle control 110 vs. 124, (P) transport of inorganic ions 32 vs. 20 for strain AT9 and B. virosa respectively).

**Conclusion**

On the basis of phenotypic, chemotaxonomic, phylogenetic and genomic information, a novel species belonging to the genus Butyricimonas is proposed with the name *Butyricimonas phoceensis* sp. nov. The type strain is AT9. This bacterium was isolated from the faeces of a 57-year-old obese French woman living in Marseille after bariatric surgery. The isolation of this new species demonstrates that microbial culturomics extends the repertoire of human gut anaerobes, which are of critical importance to decipher the links among gut microbiota, health and disease, including obesity.

**Taxonomic and nomenclatural proposals**

Description of strain AT9 sp. nov. *Butyricimonas phoceensis* (pho-ce-en-sis, N.L. gen. n. phoceensis, based on the acronym of the Phocean city where the type strain was isolated). Cells are Gram-negative-staining, non–spore forming, motile, rod-shaped bacilli, with a size of 0.5 to 1.5 μm in diameter. Colonies are opalescent with a diameter of 1 to 2 mm on 5% sheep blood–enriched Columbia agar. The strain is oxidase negative and catalase positive. It has an optimum growth temperature of 37°C and is anaerobic, but it is able to grow in microaerophilic condition at 28°C. Using API Gallery systems, positive reactions were observed for alkaline phosphatase, esterase (C4), esterase lipase (C8), naphthol-AS-BI-phosphohydrolase, phosphatase acid, N-acetyl-β-glucosaminidase, indole, D-glucose, D-lactose, glycogen and D-mannose, esculin ferric citrate and potassium 2-ketoglucenate. Cells are susceptible to gentamicin 500 μg, vancomycin, doxycycline, trimethoprim–sulfamethoxazole, rifampicin, penicillin G and teicoplanin. The major fatty acid detected was iso-C15:0. The length of the genome is 4 736 949 bp with 42.51% G+C content. The 16S rRNA gene sequence and whole-genome shotgun sequence of *B. phoceensis* strain AT9 were deposited in EMBL-EBI under accession numbers LN881597 and FBY600000000, respectively. The type strain AT9 (= CSUR P2478 = DSM 100838) was isolated from the stool sample of a French obese woman. The habitat of this microorganism is the human digestive gut.
