Abstract—In this work we briefly present Mag-Gripper, a novel robotic gripper specifically designed for autonomous clothing manipulation. It is capable of improving the grasp repeatability and precision, compensating uncertainties in the desired grasping locations by exploiting a proper magnetic force. It is an augmented jaw gripper, equipped with an electromagnet capable of attracting small metal parts suitably placed on the garment to be grasped. Mag-Gripper can find applications either in Research labs investigating Machine Learning-based clothing manipulation, either in companies having to manage a large amount of returns, either in home setting scenarios.

I. INTRODUCTION

A. Motivations

Continuously evolving robot generations are spreading out in the factories and in home settings as Service Robots. Adapting robots to perform tasks requiring complex dexterity (e.g., to manipulate deformable objects) poses new challenges. Garments are extremely challenging objects, with difficult perception and manipulation, due to the potentially infinite configurations that they can assume. To bring clothes in a desired configuration, the sequence of the intermediate movements is paramount: Each sub-movement causes a cloth configuration which, in turn, depends on the points where the cloth is grasped. Due to the deformable nature of the fabric, relatively small changes in the grasping points location can produce a significant change in the final configuration taken by the grasped garment, potentially causing a failure in the task accomplishment. On the contrary, grasping the garment in proper locations leads to a fast and effective task accomplishment, as shown in the video reported in [1] by a popular garment producer. Moreover, in the next future, assistant robots can help in our houses nicely folding our garments. As reported in the accurate taxonomy in [2], grippers usually involved in autonomous garments manipulation are not specifically thought for interacting with clothes, which are extremely deformable objects. We propose a novel approach to the problem, exploiting both grippers and garments specifically designed to be autonomously manipulated by robots. According to our vision, we developed Mag-Gripper, a novel type of jaw gripper augmented with an electromagnet. Small metal parts embedded in the garment as ornamental or brand elements are involved in the attractive gripper-clothing approach. Our long-term vision is a cooperation between researchers in robotics and producer of garment so to realize clothes that can be easily manipulated by our gripper. In the meanwhile, Mag-Gripper can have an immediate field of application in the robotic community: It is meant to be a support tool for the research in Machine Learning-based garment manipulation, where high repeatability in grasp location is a paramount issue during the data collection [3] [4].

II. THE MAG-GRIPPER

Mag-Gripper [5] has been designed to be lightweight, modular and with a limited encumbrance. The prototype has been designed via CAD and realized with additive manufacturing techniques (material used is ABS M30), which allowed small production cost and short production time. The gripper is similar to a jaw gripper, but the novelty we propose consists in having realized an augmented jaw gripper: in its central part, there is an electromagnet mounted on the top of a linear actuator. By activating the electromagnet, a magnetic field is generated, which causes a magnetic force attracting the metal part attached to the cloth. Due to the attractive motion of the metal part, a collision between the end-effector and the cloth occurs, and is detected by a small resistive force sensor (FSR), which is located near to the electromagnet. The contact is deemed to be occurred when the force measured by the sensor exceeds a given threshold, triggering the closing motion of the jaws. The proposed
gripper exploits the advantages of both the electromagnet and the jaws: the former allows to grasp the cloth in the desired point, while the latter allows a secure grasp maintenance during the cloth manipulation. In other words, the uncertainty brought by the soft fingertips of the jaws is tamed by the action of the electromagnet.

III. Experiments

Experiments with a Sawyer collaborative robotic arm (by Rethink Robotics) were performed to test the actual capabilities of the proposed gripper. To this aim, we investigated: i) how the performance are related to the size of the metal plate and the cloth weight; ii) which is the role played by the electromagnet on the configuration taken by the cloth after the grasp has occurred; and iii) how to compensate possible uncertainties on the estimate of the grasping points.

For the sake of simplicity, we assumed the desired location of the grasping point to be fixed on the garment (i.e., on a shoulder), and a fiducial marker located in that position had been used to retrieve an estimate of the desired pose with respect to the robot base. The trajectory planning was implemented in the MoveIt framework and was decomposed in three different steps: a) go 4 cm over the estimated location; b) go down until the contact between the gripper and the metal part has been detected; and c) lift the garment for 20 cm.

Concerning the aim of i), three different squared metal plates (of side 0.8, 1.8, 2.5 cm) were used. Moreover, 4 different garments were involved in the experiments (a YCB T-shirt, a mid-season pullover, an old bib and a terry guest towel). As it can be easily envisaged, the larger is the plate, the larger is the potential contacting area and the capability of compensating undesired uncertainties on the grasp location, thus increasing the grasp success rate. Experiments revealed also that the garment thickness is more relevant than the overall object weight: changing the thickness results in varying the local mass the electromagnet has to attract.

Regarding ii), E and WE experiments were conducted, activating and not activating the electromagnet, respectively. 10 grasping attempts were performed for each condition. What happens is that when the grasp execution relies on the presence of the electromagnet (E experiments), the distance between the jaws tips during the grasp execution is smaller than in the case where the electromagnet is not exploited (WE experiments). Moreover, from a qualitative point of view, the part of the cloth located between the jaws was significantly crinkled during WE experiments. Hence, the electromagnet exploitation allows a sort of extended point-like contact resulting in a more predictable configuration of the clothing, which is an high deformable object with potentially infinite ways of being deformed.

Concerning iii), an error of 1 cm on the x and y coordinates of the estimated grasping point was introduced by purpose, and 10 grasping attempts were performed. 7 grasps resulted to be successful. To increase the grasp success rate, the presence of the electromagnet suggested the possibility of performing a sort of partially-blind grasp, as a strategy to be applied when the vision system is not particularly reliable. According to this strategy, the robot is first commanded to reach the estimated grasping point and, if the contact between the object and the gripper is not detected, the robot starts spanning a small area around the estimated grasping point to exploit the magnetic attraction. However, the success of the blind grasping is highly dependent on the distance between electromagnet and garment which, in turn, depends on the thickness of the cloth. To get a more generalized planning strategy, further investigations are needed.

IV. Conclusions

In this extended abstract, we briefly presented Mag-Gripper, a novel augmented jaw designed for autonomous clothes manipulation. The only working assumption is to deal with garments provided with small metal parts. Mag-Gripper is equipped with an electromagnet: The electromagnet is exploited to establish an extended point-like contact with the garment, while the jaws allow a secure grasp maintenance during the manipulative motion. Experiments performed with a collaborative robotic arm showed that the exploitation of the magnetic force allows to perform a repeatable grasp execution and to compensate vision-based planar uncertainties on the estimation pose of the desired grasping point. Moreover, the extended point-like contact caused by the electromagnet allow to perform grasp without unnecessary wrinkles, achieving clothing configurations more suitable to vision-based Machine Learning techniques for autonomous manipulation. Future work will focus on testing the gripper in robotic setups for bimanual autonomous clothes manipulation. Moreover, the proposed blind grasp strategy will be further investigated, as a method to be applied when the vision system is not sufficiently reliable.
