Abstract
The U.S. Department of Energy's (DOE) Colorado East River Community Observatory (ER) in the Upper Colorado River Basin was established in 2015 as a representative mountainous, snow-dominated watershed to study hydrobiogeochemical responses to hydrological perturbations in headwater systems. The ER is characterized by steep elevation, geologic, hydrologic and vegetation gradients along floodplain, montane, subalpine, and alpine life zones, which makes it an ideal location for researchers to understand how different mountain subsystems contribute to overall watershed behaviour. The ER has both long-term and spatially-extensive observations and experimental campaigns carried out by the Watershed Function Scientific Focus Area (SFA), led by Lawrence Berkeley National Laboratory, and researchers from over 30 organizations who conduct cross-disciplinary process-based investigations and modelling of watershed behaviour. The heterogeneous data generated at the ER include hydrological, genomic, biogeochemical, climate, vegetation, geological, and remote sensing data, which combined with model inputs and outputs comprise a collection of datasets and value-added products within a mountainous watershed that span multiple spatiotemporal scales, compartments, and life zones. Within 5 years of collection, these datasets have revealed insights into numerous aspects of watershed function such as factors influencing snow accumulation and melt timing, water balance partitioning, and impacts of floodplain biogeochemistry and hillslope ecohydrology on riverine geochemical exports. Data generated by the SFA are managed and curated through its Data Management Framework. The SFA has an open data policy, and over 70 ER datasets are publicly available through relevant data repositories. A public interactive map of data collection sites run by the SFA is available to inform the broader community about SFA field activities. Here, we describe the ER and the SFA...
measurement network, present the public data collection generated by the SFA and partner institutions, and highlight the value of collecting multidisciplinary multiscale measurements in representative catchment observatories.

**KEYWORDS**
diverse watershed data, East River, hydrobiogeochemical processes, mountainous watershed observatory, watershed function science focus area, watershed function SFA data

1 | DATA SET NAME

The Colorado East River Community Observatory Data Collection.

2 | SITE DESCRIPTION

The East River community observatory (ER) in the Upper Colorado Basin, United States (39.033° N 107.12° W, 38.83° N 106.88° W) is a 300 square kilometre headwater catchment representative of watersheds in the Rocky Mountains of the western United States (Hubbard et al., 2018). The ER contains significant geological, hydrological, vegetation, and climatic gradients, and spans first-order mountain streams to higher-order meandering floodplains across four drainages— the East River, Washington Gulch, Slate River, and Coal Creek (Figure 1). The mean annual air temperature in the ER is ~2.4°C, with average daily temperatures of ~7.6°C and 13.4°C in December and July, respectively, as measured at the Butte SNOTEL station. The

**FIGURE 1** Map of ER site and measurements of the SFA and some collaborators. The yellow line indicates the East River community observatory domain. The red lines indicate the major drainage boundaries of the East River, Washington gulch (Wash. Gul.), Slate River, and Coal Creek. The blue lines show stream flow lines determined from the National Hydrography Dataset (U.S. Geological Survey, 2001). Measurements by community partners in the Slate River and Redwell basin are not shown. The white box shows the intensively sampled Pumphouse subregion, which includes measurements along a hillslope transect and the meandering floodplain of the East River.
average precipitation, which is mostly snowfall, is 1200 mm.yr\(^{-1}\). The watershed has an average elevation of 3266 m, with an average slope of 18.7 ± 10.9 degrees.

The ER lithology consists of igneous formations intruding into carbon-rich marine shale in the Mancos Formation, as well as sedimentary strata grading older (Permain) to younger (Tertiary) as one moves east to west across the ER domain with pockets of significant mineralization (Carroll, Bearup, et al., 2018; Carroll, Williams, et al., 2018; Gaskill, 1991). The watershed comprises montane, subalpine, and alpine life zones that collectively include aspen, meadow, mixed conifer, sagebrush, grasses, and sedges. Further details about the ER are provided in Hubbard et al. (2018) and Carroll, Bearup, et al. (2018).

Since 2015, the ER has been the primary field site for the Watershed Function Scientific Focus Area (SFA; http://watershed.lbl.gov) led by Berkeley Lab, and is one of several U.S. Department of Energy testbeds conducting interdisciplinary research to gain a predictive understanding of watershed functioning and their response to perturbations using measurements and modelling from the bedrock through soil and vegetation to the atmospheric interface. The ER serves as a community testbed for over 30 collaborating institutions that collectively aim to understand the impacts of perturbations, such as drought and early snowmelt, on the hydro-biogeochemical dynamics of mountainous, headwater catchments at seasonal to decadal timescales.

3 | EAST RIVER MEASUREMENTS, FIELD AND DATA MANAGEMENT INFRASTRUCTURE

The SFA and collaborators have collected sample- and sensor-based measurements at several locations across the East River and adjacent drainages (Figure 1). Regions of particular emphasis include “SFA-intensive” sites located within representative meanders and a hillslope in a lower montane subregion (labelled ‘Pumphouse’) of the pristine East River drainage basin, where several cross-disciplinary, co-located measurements are being conducted. Additional “satellite” sites targeting specific research questions are located near the Brush Creek confluence floodplain, an elevation gradient of research meadows along Washington Gulch and on the flanks of Cinnamon Mountain and Mount Baldy, Snodgrass Mountain, and mining-impacted sites in both Coal Creek and the Redwell Basin.

The ER instrumentation network maintained by the SFA and collaborators includes 15 stream-gaging and water quality stations used to obtain paired concentration-discharge measurements, 6 weather stations with soil moisture and temperature probes, 18 instrumented groundwater wells (e.g. Figure 2(a)–(c)), and about ~40 piezometers, ~15 ecohydrological sensor stations, and ~40 digital phenocam locations (Varadharajan et al., 2020). An eddy flux tower is maintained in the East River floodplain by the National Center for Atmospheric Research (NCAR). Extensive measurements of depth-resolved snow density, snow water equivalent, whole snowpit and rain chemistry, and stable isotopes of snow, rain and snowmelt water have been conducted over multiple years to inform stream water sources (Fang et al., 2019). Snowmelt manipulation experiments in vegetation plots in different mountain life zones were used to study the impacts of snowmelt timing on vegetation phenology (Figure 2(d)). Metagenomic analyses of microbial communities have been conducted for soils and sediments representing various locations across the floodplain meanders and lower montane hillslopes that contribute water and solutes to the river (Lavy et al., 2020; Matheus Carnevali, Hobson, et al., 2020; Matheus Carnevali, Lavy, et al., 2020; Sorensen et al., 2020), resulting in over 5000 metagenome-assembled genomes. In addition, several multi-institutional remote sensing campaigns have been conducted at the ER which include a 2015 Light Detection and Ranging (LiDAR) survey led by the SFA (Wainwright & Williams, 2017), Airborne Snow Observatory (ASO) flights by the National Aeronautics and Space Administration’s Joint Propulsion Laboratory (NASA JPL) in 2016, 2018, and 2019 (Painter et al., 2016), a 2017 USGS Airborne Electromagnetic survey, and a 2018 National Ecological Observation Network (NEON) hyperspectral survey paired with an extensive ground-based campaign conducted in coordination with Stanford University (Chadwick et al., 2020). In 2021, a two-year deployment of the DOE’s Atmospheric Radiation Measurement (ARM) Program mobile Surface Atmosphere Integrated Field Laboratory (SAIL) will use more than three dozen instruments to collect a suite of meteorology, clouds, aerosol and other atmospheric measurements in the ER (http://sail.lbl.gov). The SFA’s ER measurement locations are viewable through a public, user-friendly field information portal (https://wfsfa-data.lbl.gov/watershed/).

The ER watershed also has infrastructure maintained by several federal, state, and local agencies that have different data systems (some of these are indicated in Figure 1). Notably, the Rocky Mountain Biological Laboratory (RMBL, https://www.rmbl.org/) is situated in the townsite of Gothic, and has over 90 years of data collection activities in the watershed. Snow measurements and associated meteorological data are available from the National Resources Conservation Service (NRCS) snow Telemetry (SNOTEL) sites ‘Butte’ and ‘Schofield Pass’, Crested Butte Cooperative Observer Network (COOP), and a number of Weather Underground stations. The USGS maintains gaging stations (located downstream of the SFA gages), and collects water quality measurements across the East-Taylor watersheds, and makes the data available through NWIS (HUC: 14020001). Additional water quality data are available from the National Water Quality Portal, which includes measurements by the U.S. Environmental Protection Agency (EPA), Colorado Department of Public Health and Environment (CDPHE), and local groups including the Coal Creek Watershed Coalition and the Rivers of Colorado Water Watch. The EPA also maintains a National Atmospheric Deposition Program (NADP) and Clean Air Status and Trends Network (CASTNET) station at Gothic.

Thus collectively, the SFA and its collaborators generate diverse, multiscale datasets at the ER including hydrological, (bio)geochemo-cal, climate, vegetation, geophysical, microbiological, and remote sensing data. Additionally, several model datasets, including inputs,
outputs and preprocessing codes are generated from numerical simulations of different watershed subsystems and their aggregated behaviour.

Detailed descriptions of the data types, data variables collected, and methods used are listed in Table 1. The most commonly available data types from the ER during 2015–2020 are biogeochemistry and hydrology data.

The SFA has a Data Management Framework component that provides services and infrastructure to support the project’s data lifecycle. The framework comprises systems, workflows and scripts to acquire and store data in a queryable database, conduct QA/QC, integrate project data with external data for real-time queries, discover and download data, and to publish data with digital object identifiers (DOIs) in the DOE’s Environmental Systems Science Data Infrastructure for a Virtual Ecosystem (ESS-DIVE) repository (Varadharajan et al., 2019). Additionally, the SFA has developed an integrated field-data workflow to acquire critical metadata from these diverse data streams, and to manage data at each stage of the scientific process. The field-data workflow outlines guidelines for managing metadata and identifiers for field locations, samples, sensors, and data package creation and publication. While developed by the SFA, the workflow is available to other collaborating organizations, and is built based on community feedback and established data management best practices.

4 | SCIENTIFIC IMPACT OF ER DATASETS

The multidisciplinary data from the ER have advanced the understanding of hydrological processes in mountainous catchments, and the simultaneous collection of diverse data types across the watershed allows researchers across institutions to share knowledge and draw conclusions. Examples of datasets collected through periodic sampling or from sensor instrumentation that are frequently used in analysis and modelling include daily river stage observations and discharge estimates (dataset 43 in Table S1; observed measurement errors ranging from ~2–15%), weekly-daily surface and groundwater geochemistry (e.g., datasets 3, 5, 9, 15, 21, 41; measurement uncertainties in Table S1), and instantaneous groundwater elevations and temperature in the hillslope and floodplain (e.g., datasets 30, 46). Examples of research topics that ER datasets are used for include water partitioning as a function of hydrological perturbations such as drought and early snowmelt (e.g., datasets 18, 26, 39–44), surface-groundwater interactions (e.g., datasets 63–68), nitrogen cycling and export to the river (e.g., datasets 15, 20, 21, 27, 31–32, 52, 56), the impact of weathering and other processes on river water composition (e.g. datasets 10, 28, 32), and more broadly an aggregated understanding of watershed hydrobiogeochemical processes given their variation over space and different watershed functional zones and compartments (e.g. datasets 49–54).
### Table 1

ER data types, variables, and methods of data generation. Methods and instruments used, and uncertainties (if available) are described in the published datasets on the repositories. Several time series measurements are ongoing; see Varadharajan et al. (2020) for location and instrumentation metadata associated with these measurements. Table S1 has the full list of 71 East River datasets spread across different repositories; some datasets are listed under multiple data types.

| Data type                  | Data variables                                                                 | Methods/instrumentation                                                                 | Datasets                                                                                                                                                     |

The ER datasets have been used in numerous publications of which a select few are highlighted here. For example by combining measurements of river, rain, groundwater and snow chemistry, stream discharge, remote sensing (LIDAR, ASO), Carroll, Bearup, et al. (2018), Carroll, Williams, et al. (2018), Carroll, Manning, et al. (2019) found that groundwater recharge, an important contributor to streamflow, is dependent on elevation and vegetation (datasets 42–44, 51, 70–72). Specifically, groundwater recharge increases in higher elevations such as the upper subalpine zone, where there is greater snow accumulation and lower canopy cover. Through analyses of data on groundwater chemistry, water table depth, and rock mineralogy, Wan, Tokunaga, Williams, Brown, et al. (2019), Wan, Tokunaga, Williams, Dong, et al. (2019) found that the seasonal water table depth determines the weathering zone and weathering front in sedimentary bedrock, and that the Mancos shale can be a significant contributor to river nitrogen exports (datasets 30–32). Combining snow measurements with metagenome analysis, Sorensen et al. (2020) found that snowmelt triggers a pulse of nitrogen in hillslope soils concomitant with a collapse in microbial biomass, and changes in microbial community composition (datasets 17, 20). Using model simulations of floodplain meanders and regions of hyporheic exchange, Dwivedi et al. (2017, 2018) found these subsystems exert critical controls on nitrogen cycling and other solute exports to the river (datasets 29, 46–47).

The interdisciplinary data from the ER can also be used in future investigations that address science questions identified by the broader community such as the impacts of climate change and extreme events on the critical zone, and the scale dependence of hydrology (Blöschl et al., 2019). These data along with future measurements from the SAIL campaign will provide integrated observational datasets for benchmarking atmospheric and hydrological models in mountainous watersheds, thus addressing an identified data gap in modelling mountain rain and snow (Lundquist et al., 2019). More broadly the data from the ER will help understand the impacts of hydrological perturbations on water availability and quality in mountainous watersheds of the Western United States.

### Table 1 (Continued)

| Data type | Data variables | Methods/instrumentation | Datasets |

designing multidisciplinary watershed observatories using open science by design principles, and publishing data generated in open, public repositories (Stegen et al., 2019).

ACKNOWLEDGEMENTS

This research is supported as part of the Watershed Function Scientific Focus Area funded by the U.S. Department of Energy, Office of Science, Office of Biological and Environmental Research under Contract No. DE-AC02-05CH11231. This research used resources of the National Energy Research Scientific Computing Center (NERSC) and the U.S. Department of Energy's Joint Genome Institute (JGI), which are U.S. Department of Energy Office of Science user facilities operated under Contract No. DE-AC02-05CH11231. Support to Subsurface Insights for development of some of the core abilities used here under awards DE-SC0009732 and DE-SC0018447 is gratefully acknowledged. We also acknowledge the members of the Watershed SFA community who provided information about their datasets for this paper, including Erica Woodburn, Max Berkelhammer, Rich Wanty, Curtis Beutler, Heidi Steltzer, Amanda Henderson, Brian Enquist, Baptiste Dafflon, Li Li, Qina Yan, Kamini Singh, Martin Briggs, Reed Maxwell, David Cochis, Anna Ryken, Bhavna Arora, Sebastian Uhlemann, Michael Wilkins, Amelia Nelson, Ulas Karaoz, Janice Brahney, Yuxin Wu, Dana Chadwick, Boris Faybishenko, John Christensen, Wendy Brown, Nick Bouskill, Pat Sorensen, Jiancong Chen, Jiamin Wan, James St. Clair, Savannah (Bryant) Scott, Matthew Winnick, Anna Chovanes, Xiaoqin Wu, Ate Visser, Mark Raleigh, Jeffrey Deems, Joel Rowland, Michelle Newcomer, and Mariah Carbone.

DATA AVAILABILITY STATEMENT

Datasets generated by the SFA and collaborators at the ER are publicly available in online repositories, including ESS-DIVE, NCBI, United States Geological Survey (USGS), NASA DAAC: National Snow and Ice Data Center, Figshare, and HydroShare (as listed in Table 1 of the Supplementary Information). The SFA alone has several public datasets with associated metadata available on ESS-DIVE that include many of the long-term monitoring and spatially-extensive remote sensing and associated ground campaign datasets. A majority of the ER data collection can be accessed on ESS-DIVE through the East River watershed portal (https://data.ess-dive.lbl.gov/portals/east-river-watershed). Users must be logged into ESS-DIVE with their ORCID credentials to download the public data packages. Large datasets such as the remote sensing or model products are stored and distributed through public data transfer nodes on the DOE’s National Energy Scientific Computing Center (NERSC) usage policies. The usage license, measurement uncertainties, quality checking process, and dataset metadata are specific to each dataset and should be obtained directly from the published data in the listed repositories.
