Are intangibles really a source of future economic benefits? Evidence from the technology sector

Ilídio Tomás Lopes

Abstract
Purpose – The purpose of this paper is to identify the impact of intangibles as drivers of economic future benefits, in the top technological companies in the world. It also aims to identify whether the distribution of those intellectual capital (IC) drivers depends on the region and on the accounting standards, used in the preparation of firms’ financial reporting.

Design/methodology/approach – Using information from the major technological firms for a range of time of five years, a set of IC proxies were identified and regressed. Three linear models were used, and hypotheses were performed toward the identification of significant impacts on firms’ turnover prediction.

Findings – A set of intangibles was identified as significant drivers of firms’ turnover. Results suggest that the distribution of those proxies differ among regions and depend on the accounting standards. Firms from North-American evidence higher levels of intangibles, their boards composition is differentiated, additionally tending to increasingly invest in research and development activities.

Research limitations/implications – In spite of the limitations, the authors underline the sample size. However, the current approach can be replicated over time, and based in other rankings, applicable to other activity sectors and using different metrics.

Practical implications – Based on the major technological firms worldwide, the research adds value to the already known scope of intangibles, by providing additional and complimentary outcomes. A new direction, based on the scope of intangibles accounting standards used in the preparation of financial statements, was flagged toward theory and practice alignment.

Originality/value – This research adds value to the current literature by exploring the effects of intangibles in the major technological companies in the world. Focused in a sector strongly marked by innovative strategies, it provides a new and complimentary overview.

Paper type Research paper

1. Scope and research objective

The gap between theory and practice in the field of intellectual capital (IC) still remains one of the most unsolved paradigms. Firms tend to capitalize their intangible resources and include them in the statement of financial position, according the international accounting rules. Those resources, whenever capitalized, are associated with future economic benefits, such as operational revenues (turnover) and firms’ market valuation.

This research embodies an accounting approach about intangibles in the technology sector and aims to contribute to the literature by increasing the knowledge of intangibles and certify whether those intangibles are effectively associated with expected future benefits. Furthermore, it complements the research developed by Ferreira (2018), in the scope of the technological sector, which is represented by the major technological firms in the world, however following a strict accounting approach. Hence, it would be an original insight to
assess whether the results for this sector corroborate or refute the literature regarding the key role of intangibles on expected future returns, as stated in the main international accounting standards, such as the research studies carried out by Lev and Zarowin (1999), Dumay (2016) and Lopes et al. (2016).

This paper provides an accounting perspective about intangibles and their impact on turnover prediction, in particular in a sector strongly marked by technological research activities. Broadly, intangibles were selected as proxies of IC to conclude about its contribution to economic returns, in particular turnover, as the most direct indicator stated in the international accounting standards. The specific objectives consist on:

- investigating the effect of intangibles recognized in the statement of financial position (e.g. goodwill, trademarks, patents, software, etc.) on firms’ turnover; and
- evaluating on what extent some characteristics of the board of directors as a representation of human capital, contribute to predict future economic benefits.

Furthermore, it will be determined whether the distribution of those IC drivers depend on the region and on the accounting standards [e.g. international financial and reporting standard (IFRS), statement of financial accounting standards (SFAS), etc.] used in the preparation of the financial reporting.

2. Theoretical background

IC was traditionally split into several dimensions (Edvinsson and Malone, 1997; Marr et al., 2004; Zéghal and Maaloul, 2010; Kianto et al., 2014; Salehi et al., 2014; Tudor et al., 2014; Shakina and Molodchik, 2014) and introduced in the body of knowledge as the most intangible drivers, neither always measured nor internally and externally reported to stakeholders (Cañibano, 2018; Dumay, 2016; Guthrie et al., 2012). Over the past decades, the existing models have been reviewed and improved (Cañibano, 2018; Bini et al., 2016; Yousre et al., 2016; Lentjusenkova and Lapina, 2016; Ferenhof et al., 2015; Giuliani, 2015; Guthrie et al., 2012; Marr et al., 2004), exploring their structural pillars (classification, measuring and reporting), based on the main objective of linking IC theory and practice. The IC meta model provided by Ferenhof et al. (2015) probably represents the newest holistic aggregation and consolidation of IC frameworks, capturing several dimensions of IC (innovation capital; processes capital; technological capital; organizational capital; personal motivations; interpersonal relationships; knowledge, skills and attitudes; agility; customer capital; business capital; social actions; social interactions) through 83 new models over the period 2004-2014, however all of them typically aligned around the approaches traditionally consolidated and disseminated by Edvinsson and Malone (1997) and by Schiuma et al. (2008), such as structural capital, human capital, relational capital and social capital.

According to accounting standards, intangibles are expected to generate future economic benefits for the organization, which can be expected to positively contribute to the turnover generation and subsequent financial inflows. The literature broadly supports their positive and significant effect on organizational performance, considering intangible assets (IA) as the main source of competitive advantage for the firms (Ferreira, 2018; Cañibano, 2018; Grimaldi et al., 2017; Erikson and Rotheberg, 2016; Slack and Munz, 2016; Nadeem et al., 2016; Sharma and Dhami, 2016; Lopes et al., 2016; Lopes and Fraz, 2016; Bubic and Susak, 2015; Chahal and Bakshi, 2015; Shakina and Molodchik, 2014; Guo et al., 2012; Omil et al., 2011). These studies support the contribution of intangibles to profitability and performance, and their importance has been the main focus of the research in the field of accounting and finance in the past two decades, which emphasizes the relevance of this topic.

Intangibles are strongly linked with IC and corporate governance literature, in particular the importance of the board of directors as an expression of competence, professionalism, skills, knowledge, experience, culture and management abilities, to conduct the business
Board size is an important attribute of board structure and has been widely used as a proxy for human capital, complementary to other boards' characteristics, which represent the expertise and tacit knowledge of employees and management players. Uadiale (2010) conducted a study to examine the impact of board structure on corporate financial returns, investigating the composition of boards of directors in Nigerian listed firms. The findings evidence that there is a strong positive association between board size and financial returns, encouraging the companies to have a large board size (expertise consolidation) to improve corporate financial performance.

The research of Guo et al. (2012) was based on the influence of IC on the performance of biotech firms listed in the US market, discussing the relationship between intellectual human capital, technology innovation and financial performance. Research and development (R&D) expenditures and patents were also considered as part of technology innovation. The results evidence that human capital (measured by chief executive officer’s (CEO) or Vice President’s compensation and their academic background) and R&D expenses significantly support the current earnings disclosed in financial reports, decreasing performance in terms of cash flow and return on assets. Nonetheless, results evidence that R&D expenses and human capital, increase future stock returns, leveraging performance in the long term. Li and Wang (2014) examined the effect of R&D expenses, sales training and employee benefits Information Technology firms’ return on assets. The results support the assumption that only R&D expenditure and sales training have a positive relationship with return on assets, with employee expenses not being significantly correlated.

Ruiqi et al. (2017) examined the relationship between R&D expenditures and future performance in Chinese companies listed on the main board of Shanghai and Shenzhen stock exchanges and concluded that those expenditures are essential to improve firms' returns through the reduction of production costs and through the creation of new products, which constitutes a competitive advantage in a volatile market.

Relating other structural disbursements, a research carried out by Hanssens and Joshi (2010) reinforces the importance of advertising, providing conceptual and empirical evidence of a positive relationship between advertising expenditures and the market value of firms. Advertising has, simultaneously, a direct and indirect impact on firm value, which contributes to market capitalization. By allowing the firm to create its brand image, advertising helps guarantee firm’s reputation (Tanfous, 2013). The indirect impact of advertising is because of the consequent increase in the level of sales and services (turnover), which will ultimately be reflected in the company's returns. It can be argued that in sectors in which IA such as patents, software, trademarks, brands, in-progress R&D, etc., have an important influence in the total value of IA, there is a higher degree of uncertainty and a strong vulnerability to market conditions. In comparison, sectors in which IA are protected by formal mechanisms (such as customer contracts, licensing and franchising agreements and legal rights protection) tend to suffer less from the market’s fluctuations.

Diversity has not always been observed in regard to the relation between IA and the performance of the firm across countries. Nevertheless, Sharma and Dharni’s (2016) observed that the majority of research studies conducted in the USA, UK and France establish a negative relationship between the IA and performance of the firm. Other research found no relationship between performance and region (Lopes et al., 2016) and in a research on whether the IC value was perceived differently across nations, Inkinen et al. (2017) proved the similarity of IC elements across the examined countries, establishing that firms are starting to uniform IC management, and therefore, verify less variation at this level.

In a recent research regarding the effects of IC components on performance, Nadeem et al. (2016) defend that the relationship between IC and organizational performance is bidirectional, and therefore, should be considered dynamic, stating that lagged firm
performance affects current or future IC efficiency. To conclude on this assumption, the authors measured the relationship between IC efficiency and the performance of 774 firms from the London Stock Exchange. The results suggest that VAIC (value-added intellectual coefficient) is positively and significantly related to firm performance, mainly with return on assets and return on equity. When analyzing the IC’s components separately, Nadeem et al. (2016) observed that structural capital and physical capital are critical for firm performance, and human capital was only found significant when using the static approach of ordinary least squares (OLS) regression instead of the dynamic one. These results are congruent with most of the existent studies in the literature regarding the relevance of IC but highlight the importance that is still attributed to physical assets on financial performance. A similar study from Sardo et al. (2018) analyzed the effect of IC on small- and medium-sized enterprises’ (SMEs) hotel financial performance, using a sample of 934 Portuguese companies. This research adopted the generalized method of moments system estimator to analyze dynamic panel data. The findings suggested that IC components, i.e. human capital, structural capital and relational capital provide a positive impact on financial performance, with human and structural capitals presenting the higher impact on return on assets. The results support that investments in IC take time to generate profitability and return, stressing that size has a negative impact on financial performance, suggesting that larger companies are less profitable in the hotel industry.

Lopes et al. (2016) have contributed for literature with evidences that demonstrate that for the top 30 airlines worldwide, IC drivers, such as IA, are significant in the prediction of “the most direct indicator of return,” turnover. The obtained results support the importance of human capital, namely, employees’ expenses and benefits and the size of board of directors – and structural capital in the prediction of this indicator of profitability. However, the relationship between IC and other performance indicators, such as return on assets (ROA), return on equity (ROE) and return on sales, could not be validated. They also concluded that only variables associated with financial leverage and scale effects have a significant impact on profitability, with region not playing an important role on performance in this particular activity sector.

Not many studies find evidence on the negative or null impact of intangibles to performance and profitability. Amadieu and Viviani (2010) analyzed the financial statements of 207 SMEs of the wine industry and concluded on a negative impact of intangibility intensity on financial performance, measured by return on assets. The authors state that in the winery industry, IA are used in an ineffective way and, to guarantee financial success, intangible expenses should be accompanied by organizational and managerial changes. Pal and Soriya (2012) compared the IC performance between Indian pharmaceutical and textile industries using VAIC and association of IC with financial indicators such as turnover, ROA, ROE and market to book value. Results evidence that although both sectors are efficiently using IC, there was no impact of IC on the firms’ productivity, which was measured by turnover. Regarding the other measures of performance, the authors found that profitability measured by ROA increases with IC efficiency. Conversely, ROE is only positively influenced by IC in the case of the pharmaceutical industry, due to the fact of it being a knowledge intensive sector (based on dynamic innovative activities). When analyzing the market valuation of the companies, the authors found no impact of IC, which reflects the lack of consideration of intangibles in the stakeholders’ decision-making process, prioritizing other factors relative to performance.

Lopes and Ferraz (2016) examined 125 non-financial business organizations listed on an Iberian stock exchange with the objective of identifying the impact of IC and the effect of boards’ expertize and knowledge on performance. In this respect, turnover was used as the main performance indicator and return on assets, return on equity and return on sales as complementary measures. The authors concluded on the positive and significant impact of intangibles on the turnover of non-financial Iberian companies, not finding empirical evidence to support the impact on the complementary indicators. Regarding the
characteristics of the board, the study proved that the size of the board and the participation of the members on other internal or external boards of the organization are significantly associated with turnover.

In their empirical review of the major topics concerning IA, Sharma and Dharni (2016) validate the previous assertions regarding the effect of IA on firm returns across sectors. Those authors observed differences in the contribution of intangibles depending on the sector they are inserted, which they believe may be because of the difference in appropriability of intangibles. This appropriability may differ on account of the protection regimes available across sectors, nature of intangibles and the tendency of firm to leverage intangibles for business efficiency (Sharma and Dharni, 2016).

The diversity of research studies carried out on the scope of intangibles have been confirmed the contribution of the invisible side of firms to the generation of expected future benefits. Based on this preliminary assumption, this research looks for corroborative evidence on the scope of technological firms, and by exploring the importance of region and set of accounting standards used in those financial and strategic achievements.

3. Methodology and methods

3.1 Aims and objectives

The main purpose of this research is to identify the impact of intangibles on future economic benefits of the top 25 major technological firms worldwide, in line with international accounting standards. This research paradigm is related to the positive theory of accounting, which allows testing cause-and-effect relationships (Sekaran and Bougie, 2013). Hence, it is based on the prediction power of intangibles recognized and disclosed in the financial reporting, as drivers of potential economic benefits, as stated in the international accounting standards about intangibles.

3.2 Data

The sample was selected considering Forbes’ ranking “World’s 25 Biggest Tech Companies in 2016” (Forbes, 2017). The financial information used for this research was collected from companies’ annual financial statements (Appendix) – specifically from their financial annual reports and corporate governance reports (websites validity confirmed on July 02, 2019). The financial statements used relates to the period 2013 to 2017, lagged one economic period for the dependent variable (turnover). In total, 14 (56 per cent) of the firms analyzed have their headquarters located in North America, 3 (12 per cent) in Europe and 8 (32 per cent) in Asia. Relating accounting standards, 10 (40 per cent) firms use IFRS in their financial reporting and 15 (60 per cent) use other accounting standards (e.g. SFAS). The data was collected in US dollars for all the companies. The ones that had their financial information expressed in different currency measure, all monetary values were converted at the exchange rate mentioned in the corresponding reports.

3.3 Variables and theoretical framework

Variables were selected and are summarized in Table I. The time effect was also considered in the three models used in the current research.

The selected dependent variable was turnover (operational revenues), in line with accounting standards on intangibles (e.g. IFRS). Thus, turnover is the indicator, which is expected to be the most susceptible to significant effects of intangibles, as this directly measure the economic benefits obtained by a company (Hussinki et al., 2017; Lopes et al., 2016; Bubic and Susak, 2015; Li and Wang, 2014; Tudor et al., 2014; Tanfous, 2013; Gan and Saleh, 2008). The assumption of accounting standards that intangibles are associated
with future economic benefits will be supported if a positive and significant impact on these firms’ turnover is verified.

Broadly, intangible resources must be capitalized (included in the statement of financial position) if they are controlled by the owner, if they are identifiable and if future returns are expected to flow to the entity. Otherwise, their expenditure must be recognized as an expense (included in the profit and loss statement) when it is incurred, however impacting, as expected, on forthcoming revenues. The variable size of the board of directors was measured through the number of members on the board (Nath et al., 2015; Wang et al., 2013; Sheikh et al., 2013; Uadiale, 2010; Mashayekhi and Bazaz, 2008) and was used, along with the variables board of directors’ annual compensation and total number of organization’s employees, as a proxy to human capital. This study introduces the variable BDAC as a proxy to human capital, which intends to represent the expenses incurred with the members of the board in the period under analysis. This variable intends to quantify the value attributed to the knowledge of a firm’s directors. EMP was used because of the assumption that a company is better at value creation if it is more experienced and has more intensity of labor (Shakina and Molodchik, 2014). As the majority of the firms analyzed are from North America and European and Asian companies represent 12 per cent and 32 per cent of the sample, respectively, the region was split into two different blocks: North-American; and other regions. The purpose is to identify whether the distribution of the IC drivers depends on the region.

As control variables, total assets was used to represent the firm’s size, in line with previous research studies (Ferreira, 2018; Sardo et al., 2018; Lopes et al., 2016; Lopes and Ferraz, 2016; Li and Wang, 2014; Omil et al., 2011) and leverage as an indicator of the proportion of equity and debt the firms use to finance their assets, including intangibles and innovation efforts (Pal and Soriya, 2012; Sardo et al., 2018; Lopes et al., 2016; Tanfous, 2013; Wang et al., 2013).

### 3.4 Regression models

Model 1 aims to explain the effect of IA under the assumption of accounting standards, reflecting the impact of the capitalized intangibles comprised in the firms’ statement of financial position. Model 2 includes characteristics of the board of directors, to conclude on the contribution of the proxy human capital pillar (as part of IC) on turnover. Model 3 embodies capitalized and non-capitalized intangible resources (software and R&D expenses and advertising expenses), aiming to identify the disaggregated effects of intangibles on future economic benefits.

| Variable   | Description                                                                 |
|------------|------------------------------------------------------------------------------|
| TUR<sub>(t+1)</sub> | Logarithm of firm’s turnover in Y<sub>t+1</sub>                               |
| IA<sub>t</sub> | Logarithm of total IA recognized in non-current assets                       |
| GW<sub>t</sub> | Logarithm of goodwill recognized in non-current assets                        |
| LP<sub>t</sub> | Logarithm of licenses and patents valuation recognized in non-current assets |
| BTRAD<sub>t</sub> | Logarithm of brands, trade names and trademarks recognized in non-current assets |
| SRD<sub>t</sub> | Logarithm of software and research and development disbursements             |
| ADV<sub>t</sub> | Logarithm of advertising expenses                                            |
| BDSIZE<sub>t</sub> | Size of the board of directors (executive and non-executive members)        |
| BDAC<sub>t</sub> | Logarithm of board of directors’ annual compensation                          |
| EMP<sub>t</sub> | Total number of firm’s employees                                              |
| LEV<sub>t</sub> | Ratio of total book debts to total assets                                     |
| SIZE<sub>t</sub> | Logarithm of total assets                                                     |
| ASTD<sub>t</sub> | One if IFRS adopted in the preparation of financial statements, zero otherwise |

Notes: TUR = Turnover; IA = Intangible assets; GW = Goodwill; LP = Licenses and patents; BTRAD = Brands, trade names and trademarks; SRD = Software and R&D expenses; ADV = Advertising expenses; BDSIZE = Board of directors; BDAC = Board of directors’ annual compensation; EMP = Employees; LEV = Leverage; SIZE = Firm’s size; ASTD = Accounting standards.
Model 1 (effect of intangibles disclosed in firms’ financial position):

\[
\hat{Y}_{i(t+1)} = \beta_0 + \beta_1 IA_{i,t} + \beta_2 GW_{i,t} + \beta_3 LP_{i,t} + \beta_4 BTRAD_{i,t} + \beta_5 LEV_{i,t} + \beta_6 SIZE_{i,t} + \beta_7 ASTD_{i,t} + \beta_8 \text{Time effects}_{i,t} + \epsilon_{i,t}
\]

\( (i = \text{company} = 1, \ldots , 25; \ t = \text{year} = 1, \ldots , 4) \)

\( \hat{Y} = \text{TUR} \)

Model 2 (impact of human capital):

\[
\hat{Y}_{i(t+1)} = \beta_0 + \beta_1 IA_{i,t} + \beta_2 GW_{i,t} + \beta_3 LP_{i,t} + \beta_4 BTRAD_{i,t} + \beta_5 BDSIZE_{i,t} + \beta_6 BDAC_{i,t} + \beta_7 EMP_{i,t} + \beta_8 LEV_{i,t} + \beta_9 SIZE_{i,t} + \beta_{10} \text{ASTD}_{i,t} + \beta_{11} \text{Time effects}_{i,t} + \epsilon_{i,t}
\]

\( (i = 1, \ldots , 25; \ t = 1, \ldots , 4) \)

\( \hat{Y} = \text{TUR} \)

Model 3 (disaggregated effects of intangibles):

\[
\hat{Y}_{i(t+1)} = \beta_0 + \beta_1 GW_{i,t} + \beta_2 LP_{i,t} + \beta_3 SRD_{i,t} + \beta_4 ADV_{i,t} + \beta_5 BDSIZE_{i,t} + \beta_6 BDAC_{i,t} + \beta_7 EMP_{i,t} + \beta_8 LEV_{i,t} + \beta_9 SIZE_{i,t} + \beta_{10} \text{ASTD}_{i,t} + \beta_{11} \text{Time effects}_{i,t} + \epsilon_{i,t}
\]

\( (i = 1, \ldots , 25; \ t = 1, \ldots , 4) \)

\( \hat{Y} = \text{TUR} \)

3.5 Hypotheses

\( H1. \) IA have a positive and significant impact on the performance of the world’s major technological companies.

\( H2. \) Human capital contributes positively to the performance of the world’s major technological companies.

\( H3. \) The disaggregation of intangibles has a positive impact on the performance of the world’s major technological companies.

\( H4. \) SRD and ADV contribute positive and significantly to the performance of the world’s major technological companies.

\( H5. \) The distribution of the IC drivers of the North-American region is convergent with the distribution of the IC drivers of the remaining regions.

\( H6. \) The distribution of the IC drivers for the companies adopting IFRS is convergent with the distribution of the IC drivers for firms adopting other accounting standards.

4. Results and discussion

4.1 Descriptive measures

The sample integrates the top 25 technological firms. Thus, 100 observations were expected, although only 97 were effectively verified due to the absence of annual reports for three companies in specific economic periods.

It is possible to verify (Table II) that when measuring the firms’ performance through turnover, each company registered a mean of 10.57 with 0.87 of standard deviation. Regarding the independent variables, the proxies of human capital reveal a BDAC of, in mean, 14.79 (standard deviation = 1.96) with the board size being constituted by, in mean,
10 people (standard deviation = 2) and firms having a mean of 128,011 employees (standard deviation = 145,405 people). Relating the remaining intangibles, GW is the one with the higher mean of 8.53 (standard deviation = 1.75) followed by SRD with a mean of 8.22 (standard deviation = 1.21). The variables with lower means are BTRAD and LP, with means of 4.87 (standard deviation = 2.19) and 5.62 (standard deviation = 2), respectively.

### 4.2 Bivariate correlations

As stated in Table III relatively to the intangibles disclosed in firms’ financial position, IA and LP are positive and significantly associated with TUR ($r = 0.226$; $p = 0.026$ and $r = 0.389$; $p = 0.001$, respectively). Table IV introduces the human capital proxies and translates the significant and positive relation between BDSIZE ($r = 0.171$; $p = 0.094$), BDAC ($r = 0.246$; $p = 0.018$) and EMP ($r = 0.437$; $p < 0.001$) and TUR. Interestingly, EMP evidences a significantly negative correlation with BDAC ($r = -0.194$; $p = 0.066$), which suggests that the firms with more employees, offer their board of directors a lower annual compensation.

| Table II | Descriptive measures |
|----------|----------------------|
| **Variable** | N | Minimum | Maximum | Mean | SD |
| TUR | 97 | 8.975 | 12.362 | 10.5667 | 0.8697 |
| IA | 97 | 0.000 | 9.477 | 7.3237 | 1.7119 |

Notes: ***p < 0.01; **p < 0.05; *p < 0.1; TUR = Turnover; GW = Goodwill; LP = Licenses and Patents; SRD = Software and R&D expenses; ADV = Advertising expenses; BDSIZE = Board of directors; BDAC = Board of directors’ annual compensation; EMP = Employees; LEV = Leverage; SIZE = Firm’s size; ASTD = Accounting standards
strong correlation with the firms' size \((r = 0.703; p < 0.001)\) and \(r = 0.557; p < 0.001\), respectively), suggesting that larger firms expend more in R&D and advertising. BDAC is, likewise, positively correlated with the size of the firm \((r = 0.394; p < 0.001)\), indicating that larger companies offer higher annual compensation to their directors. Moreover, and as expected, the size of the firm is positively related to turnover \((r = 0.850; p < 0.001)\), reflecting the scale effects.

Model 1, which demonstrates the effect of intangibles disclosed in firms’ financial position was validated for the dependent variable \((\text{adjusted } R^2 = 92.8\text{ per cent}; F = 15.534; p < 0.001)\). Model 2, aiming to verify the impact of the human capital proxies, was also validated for TUR \((\text{adjusted } R^2 = 93.4\text{ per cent}; F = 13.590; p < 0.001)\). Model 3, representing the disaggregated effects of intangibles, was also validated for TUR \((\text{adjusted } R^2 = 96.1\text{ per cent}; F = 47.775; p < 0.001)\) Tables VI and VII.

Notes: ***\(p < 0.01); *p < 0.1; TUR = Turnover; IA = Intangible assets; GW = Goodwill; LP = Licenses and patents; BTRAD = Brands, trade names and trademarks; BDSIZE = Board of directors; BDAC = Board of directors’ annual compensation; EMP = Employees; LEV = Leverage; SIZE = Firm’s size; ASTD = Accounting standards
The results obtained in the first model allow to conclude that relating the independent explanatory variables that are statistically significant, GW has the highest impact in explaining the firms’ returns, presenting a negative relation with TUR (standardized $\beta = -0.118; p = 0.026$), contradicting the expected signal of $H1$. The remaining variables representing IA, namely, IA (standardized $\beta = 0.008; p = 0.215$), LP (standardized $\beta = -0.235; p = 0.009$) and BTRAD (standardized $\beta = 0.058; p = 0.780$) are not statistically significant to explain the model, which leads to the rejection of $H1$ due to the mixed signals evidenced. As expected, considering the literature review, the control variables LEV (standardized $\beta = 0.821; p = 0.01$) and SIZE (standardized $\beta = 1.067; p < 0.001$) are positive and statistically significant in the prediction of TUR.

Regarding the quality of the model evaluated by its explanatory capacity, the results of adjusted $R^2$ evidence that Model 1 explains in 92.8 per cent the variance of the dependent variable turnover Table VIII.

SRD and ADV evidence a positive and significant impact on TUR (standardized $\beta = 0.229, p < 0.001$; standardized $\beta = 0.069, p = 0.007$, respectively), with SRD being the independent variable that contributes the most to explain future economic benefits. Thus, $H4$ cannot be rejected.

When assessing the disaggregated effects of intangibles, the human capital proxies used in this research were found to be positive and significantly explainable of turnover in the case of BDSIZE (standardized $\beta = 0.066; p < 0.001$) and EMP (standardized $\beta < 0.001; p < 0.001$), not rejecting $H2$. Contrarily, BDAC was found not to be statistically significant in the prediction of TUR (standardized $\beta = -0.021; p = 0.271$) causing the rejection of $H2$ for this variable. As the IA evidence a negative impact on TUR and human capital proxies present mixed effects, no conclusions can be taken regarding $H3$, which cannot be broadly validated.

Although SIZE is positive and significantly associated with TUR (standardized $\beta = 0.784; p < 0.001$), contrarily to the observations on Models 1 and 2, LEV was excluded from the significant variables (standardized $\beta = 0.162; p = 0.376$).

### 4.3 Distribution of the intellectual capital drivers (region and accounting standards)

To complement the statistical analysis, $t$-test for equality of means was performed for the different regions. The sample of 25 technological companies consists of 14 companies from...
North-America (56 per cent), 3 from Europe (12 per cent) and 8 from Asia (32 per cent), which were split into two different groups: North-American companies (56 per cent) and non-North-American companies (44 per cent).

The null hypothesis \((H_0)\) assumes that the distribution of the IC drivers of the North-American region is convergent between regions and between accounting standards adoption. Observing the evidences stated in Table IX, there is statistical evidence to reject \(H_0\) for the variables \(TUR\), \(IA\), \(GW\), \(LP\), \(SRD\), \(BDSIZE\) and control variables \(SIZE\) and \(LEV\), proving these variables present different distributions depending on the region \((H_5)\). In fact, these variables display significantly higher means when considering the North-American region.

From the variables that rejected the null hypothesis, it is possible to observe that \(TUR\) has a higher mean in the North-American companies (mean = 10.84) than in the European and Asian ones (mean = 10.21). Furthermore, all the IA disclosed in firms’ financial position, with the exception of BTRAD, reflect a higher mean for North-America in comparison with the non-American region. Of the human capital proxies, \(BDSIZE\) is the only whose distribution is different between regions, with North-American companies having, in mean, 11 directors on the boards and the remaining firms having, in mean, 9 people representing their board of directors. \(SRD\) also shows a higher mean in the case of North-American companies (mean = 8.70) versus the remaining regions (mean = 7.60), which can reflect a superior investment in research and development from US companies.

Relating the accounting standards adoption for intangibles recognition and measurement, the rejection of the null hypothesis for the intangibles included in the three models, highlights that intangibles recognition and measurement depend on the accounting standards used in the preparation of the financial statements \((H_6)\). Thus, a new direction of research is signalized to explore the convergence, in particular between firms using IFRS and firms using other accounting standards.

### Table IX

5. Concluding remarks

Model 1, which reflects the impact of the capitalized intangibles comprised in the companies’ statement of financial position, evidenced a negative contribution of GW to TUR, with the remaining IA not being significant to explain turnover. The negative signal of GW is supported by Heiens et al. (2007) and may be due to the assets not translating the economic benefits expected by firms. Model 2 includes characteristics of the boards of directors to conclude on the contribution of human capital to firms’ future returns. EMP evidenced a positive impact on TUR, confirming the proposition of Shakina and Molodchik (2014), although no significant relation was found between the remaining human capital variables and performance in this model. The aggregated measure of IA evidenced a negative impact on TUR. Model 3 embodies IA along with intangible resources (software and R&D expenses and advertising expenses) and human capital, aiming to identify the disaggregated effects of intangibles on turnover. In this model, GW and LP evidenced a significant, although negative, impact on TUR, reflecting isolated effects that were not captured in Model 2, where the total amount of IA can explain the variance observed for turnover. Similarly, the human capital proxy BDSIZE becomes relevant to estimate TUR, suggesting that when considered alongside disaggregated measures of intangibility, the size of board of directors becomes important to enhance expected returns. Although this model’s results do not allow the validation of hypotheses regarding the disaggregated influence of intangibles, an isolated effect can be observed for some variables, exhibiting synergetic effects when considered together. Model 3 also includes the variables SRD and ADV, both contributing to operational economic revenues measured through TUR.

This paper also assesses whether the distribution of the intangibles (IC drivers) depends on the region of the firm by splitting the sample in two groups and comparing the means of the North-American region with the remaining regions. Results suggest that the distribution of IC is different among regions for the variables IA, GW, LP, BDSIZE and SRD, as well as for the indicator TUR and control variables. These variables evidence higher means for the North-American region, which indicates that US companies have higher levels of IA, GW and LP, their boards are generally constituted by more members and they tend to invest more in R&D activities. North American firms also present a higher mean regarding the size and turnover of the business, implying that those firms are larger than European and Asian ones, and have higher levels of economic returns. Furthermore, this research also suggests that the capitalization of intangible resources can be associated with the accounting standards used in the preparation of the financial statements. This evidence can serve as a starting step for further developments on the topic.

Regarding suggestions for future research, it would be interesting to explore other variables as intangibles and human capital proxies to determine if it would originate different results for this sample. Moreover, the study would benefit from an analysis over a longer period and for a larger sample, to conclude on the impact of IC on future economic returns.
