Abstract

Background

Growing evidence indicates that poor sleep harms health. Early to bed and early to rise is considered as a healthy lifestyle in Chinese population. The current study aimed to examine the effects of sleep habits on acute myocardial infarction (AMI) risk and severity of coronary artery disease (CAD) in Chinese population from two centers.

Methods

A total of 873 patients including 314 AMI and 559 controls were recruited from the inpatient cardiology department of the Affiliated Jiangning Hospital and the First Affiliated Hospital of Nanjing Medical University. 559 controls included 395 CAD cases and 164 non-CAD cases. We used a 17-item sleep factors questionnaire (SFQ) to evaluate sleep habits comprehensively by face-to-face interview. The severity of CAD was assessed by Gensini score in AMI and CAD groups. The effects of sleep factors on AMI risk and Gensini score were examined by unconditional logistic regression.

Results

After mutually adjustment for other sleep factors and demographic characteristics, the timing of sleep (24:00 and after), sleep duration (< 6h) and frequency of night-time waking (3 times) were associated with increased risk of AMI. In subjects with age < 65 years, sleep duration (< 6h) was correlated with increased risk of AMI (OR 3.096, 95%CI 1.435–6.681, P = 0.004) and daytime napping was related to reduced risk of AMI (OR 0.620, 95%CI 0.397–0.970,P = 0.036). In the population aged ≥ 65 years, the level 3 of light exposure (they could see only the hazy outline of the bedroom) was correlated with lowered risk of AMI. Late sleep timing (24:00 and after) and the frequency of night-time waking (3 times) were associated with increased risk of AMI independently of age. Moreover, Short sleep duration was correlated with increased risk of high Gensini score.

Conclusion

Late sleeping is an important risk factor for AMI. Daytime napping may protect the population aged < 65 years.

Introduction

It has been reported that sleeping between 7h and 9h per night is the best choice for adults [1]. However, sleep insufficiency caused by stressful work and addiction to cell phone has become a common
phenomenon in real world life. Growing evidence indicates that poor sleep harms health, either physical or psychological.

Short sleep and poor sleep quality increase the risk of cardiovascular disease often through influencing glucose metabolism and blood pressure and leading to insulin resistance and metabolic syndrome [2]. A longitudinal study proved that sleep for 6h or less per night lost less weight and increased the risk of type 2 diabetes mellitus [3]. Unsurprisingly, consistent results were showed that short duration of sleep increased the incidences of obesity and metabolic syndrome [4, 5]. Improving sleep quality was helpful to weight control [6]. Compared with individuals with 7h of sleep per night, those with 6h or even shorter had a higher risk of hypertension [7]. The relationship between sleep duration and coronary artery disease (CAD) displays a U-shaped curve, which means that short or long sleep is associated with a high risk of CAD. The association between long sleep and CAD risk has been verified in a meta-analysis [8].

Moreover, much evidence supports that CAD is closely correlated with sleep-related factors, such as sleep quality, siesta, insomnia, shift work and so on [9–12]. Gensini score is calculated based on the location and severity of stenosis in coronary lesions [13]. Patients of high Gensini score are usually accompanied with moderate to severe obstructive sleep apnea [14], suggesting that a positive correlation existed between Gensini score and the severity of sleep apnea [15].

However, the effect of timing of sleep on cardiovascular disease and Gensini score has received scant attention. Early to bed and early to rise is considered as a healthy lifestyle in Chinese population, especially in the elderly. In the same condition of sleep duration at night, the elderly Chinese go to bed and get up about 1 hour earlier than the elderly Europeans [16]. An interesting finding is that chronotype is associated with the onset time of acute myocardial infarction (AMI) [17], indicating that AMI incidence differs in different sleep-wake habits schedules.

Therefore, whether the traditional early sleep-wake habits could reduce the risk of AMI and severity of CAD is worth discussing. We designed this study to explore the influences of sleep habits on AMI risk and Gensini score in Chinese population from two centers.

**Methods**

**Subjects**

From April 2019 to June 2020, a total of 873 patients were consecutively recruited from the inpatient cardiology department of the Affiliated Jiangning Hospital and the First Affiliated Hospital of Nanjing Medical University. Patients hospitalized and diagnosed as non-AMI during the same time period were matched. Of them, 314 cases were AMI and 559 cases were controls (395 CAD and 164 non-CAD). All patients underwent coronary angiography and CAD was defined as at least one main coronary artery with > 50% narrowing of luminal diameter. Patients were diagnosed as MI when a cardiac biomarker (preferably cardiac troponin) rose or fell at least one value in its 99th percentile upper reference limit and at least one of the following criteria was met, including ischemic symptoms, electrocardiogram (ECG)
changes of new ischemia, pathologic Q waves in the ECG, imaging evidence of new loss of viable myocardium or new regional wall motion abnormality, identification of an intracoronary thrombus by angiography or autopsy [18]. Patients were excluded if they had mental diseases, sleep apnea, chronic obstructive pulmonary disease, stroke sequelae, arthritis, renal failure, tumor and a history of revascularization.

Study design

After patients were in stable condition, trained physicians administered a questionnaire survey by a face-to-face interview. Information on demographic characteristics, hypertension, diabetes and dyslipidemia history, drug use, smoking, drinking, dietary habits, exercise and sleep habits were collected. We used Gensini score to evaluate CAD severity according to coronary angiography in AMI and CAD groups [19]. Body height and weight were measured for all patients and body mass index (BMI) was calculated as weight (kg) divided by the square of height (m\(^2\)).

Sleep study

In order to evaluate sleep habits comprehensively in the last year before enrollment, we employed a 17-item sleep factors questionnaire (SFQ) which had been proven to be reliable and valid previously [20]. SFQ included sleep quality, sleep duration at night, timing of sleep and waking up, insomnia and nighttime waking frequency, sleep medication use, night work, daytime napping, light at night (LAN) exposure and sleep noise. Sleep quality was categorized as very poor, fairly poor, fairly good and very good by self-evaluation. LAN exposure was categorized into four levels: (1) they could read comfortably; (2) they could barely read; (3) they could see only the hazy outline of the bedroom; and (4) participants wore a mask to keep out light, or they could not see their hand in front of their face [20]. Sleep duration was divided into < 6h, 6-9h, >9h. The habitual timing of sleep was classified into before 22:00, 22:00 to 23:00, 23:00 to 24:00, and 24:00 and after. The timing of morning waking was classified into before 6:00, 6:00 to 7:00, and after 7:00. Napping at least 5 days per week was defined as regular daytime napping [21].

Statistical analysis

Non-normally distributed continuous variables were expressed as median (interquartile range) and Mann–Whitney U-test was used to compare medians. Categorical variables were expressed as number (proportion) and the Chi-square test was used to test the distribution. When we analyzed the association between Gensini score and sleep factors, patients with no or mild coronary artery stenosis in non-CAD group were eliminated. Gensini score was divided into two groups by median value. The associations between sleep factors and AMI risk and Gensini score were examined by unconditional logistic regression. Every epidemiological variable was tested by single variable logistic regression analysis, and the variables with P < 0.1 and well-recognized AMI risk factors were adjusted. Accordingly, all sleep factors were adjusted for age, sex, BMI, residence, history of diabetes, hypertension and dyslipidemia, history of CAD, use of statins, antiplatelet agents, beta-blockers, angiotensin converting enzyme inhibitor (ACEI) or angiotensin receptor blocker (ARB), smoking, drinking, diet, regular exercise and education level.
Moreover, every sleep factor was adjusted for other sleep factors else. We used 65 years as the cutoff point in the subgroup analysis because the persons aged ≥ 65 years are defined as the elderly in China. The adjusted odds ratios (ORs) and 95% confidence intervals (CIs) were calculated. The difference was considered as significant if P < 0.05. All analyses were carried out using SPSS 20.0.

Results

Comparison in demographic characteristics between AMI and control groups

We enrolled 873 patients in total, with 314 AMI patients and 559 controls (395 CAD and 164 non-CAD). The characteristics and comparisons between AMI and controls are presented in Table 1. The comparisons between AMI and CAD group and non-CAD group are shown in Supplementary Table 1. The median age was lower and the proportion of men were significantly higher in the AMI group than in the control group. The education level, hypertension, use of ACEI or ARB, smoking, drinking, diet and regular exercise of the AMI group also significantly differed from the control group.

Differences in sleep factors between AMI and control groups

Sleep factors were compared between AMI and control groups (Table 2). Significant differences were found in timing of sleep and morning waking, sleep duration at night, frequency of insomnia and night-time waking, sleep medication use, LAN and night work. However, there were no significant differences in sleep quality, daytime napping and sleep noise.

Associations between sleep factors and AMI

Table 3 presents the results of logistic regression analyses. The timing of sleep and morning waking, sleep duration, sleep medication use, LAN, frequency of night-time waking, night work and daytime napping were significantly associated with the risk of AMI in crude analyses. After mutually adjustment for other sleep factors and demographic characteristics, the timing of sleep (24:00 and after), sleep duration (<6h) and frequency of night-time waking (3 times) were associated with increased risk of AMI. Compared with level 1 (they could read comfortably) of LAN exposure, level 3 (they could see only the hazy outline of the bedroom) was associated with lowered risk of AMI. In contrast to expectation, a positive correlation was observed between sleep quality and AMI.

Subgroup analysis of the associations between sleep factors and AMI

The associations between sleep factors and AMI changed in stratified analysis by age (Table 4). In subjects with age <65 years, sleep duration (<6h) was associated with increased risk of AMI (OR 3.096, 95%CI: 1.435-6.681, P=0.004). Daytime napping was related to lowered risk of AMI (OR 0.620, 95%CI: 0.397-0.970, P=0.036). Moreover, sleep quality was positively correlated with AMI. In those age ≥65 years, the level 3 of LAN was associated with reduced risk of AMI (OR 0.048, 95%CI: 0.005-0.435, P=0.007). Significant associations were observed between late sleeping time (24:00 and after) and the frequency of night-time waking (3 times) and AMI in both age groups.
Associations between sleep factors and Gensini score

The median value of Gensini score was 42.0, and the high and low score groups included 352 and 357 patients respectively. The characteristics comparisons between high and low score groups are shown in Table 5. Statistically significant correlations were found between Gensini score and the timing of sleep, sleep duration, sleep quality, sleep medication use and the frequency of night-time waking. However, after adjusting for demographic characteristics in Table 5, the associations between the timing of sleep, sleep medication use and the frequency of night-time waking and Gensini score disappeared. Only the association between sleep duration and Gensini score remained significant after adjustment for both demographic characteristics and other sleep factors (Table 6).

Discussion

Our study demonstrated the associations between sleep factors and AMI risk and CAD severity. Consistent with previous researches, short sleep duration at night was obviously correlated with AMI and CAD severity in this study. Hormonal disorders, like an increase of ghrelin [22] or cortisol [23], contribute to the development of obesity [22], diabetes [24] and inflammation [25]. Both obesity and diabetes are risk factors for AMI, leading to an increase of AMI. Short or long sleep duration increases the incidence of type 2 diabetes [26], stroke [27], CAD [27] and arterial stiffness [28]. Long sleep duration can also bring other cardiovascular risk factors, like tobacco use [29] and sedentary lifestyle [30]. But the association between long sleep duration and AMI was not proven in our research, which may be due to its small sample size.

Gensini score has been widely used to assess the extent of CAD in clinic. Coronary artery calcification (CAC), quantitated by CAC score, is a hallmark in the formation and accumulation of atherosclerotic plaque [31]. CAC score and carotid artery intima-media thickness, can be measured as Gensini score to assess the severity of CAD [32]. It was demonstrated that short duration of sleep was associated with higher carotid artery intima-media thickness [33] and incidence of CAC [34]. In our research, shorter sleep duration was also correlated with high Gensini score after adjusting for demographic characteristics and other sleep factors.

Sleep duration is determined by the time of falling asleep and waking up. Therefore, sleeping late, leading to insufficient sleep, is harmful for both adults [35] and adolescents [36]. Furthermore, circadian misalignment due to late sleeping may increase the risk of hypertension [35], obesity [37] and type 2 diabetes [38]. Evening and morning chronotypes are usually divided according to the preference to choose which time of the day for daily activities [39]. Compared with morning chronotypes, evening chronotypes are more likely to encounter health problems, such as the prevalence of smoking, unhealthy diets, sedentary behavior [38, 40]. In people with evening chronotypes, the incidence of type 2 diabetes rises by 2.5 folds and arterial hypertension by 1.3 folds, independent of sleep duration [38]. A Cox regression analysis reveals a 1.15-fold increased risk of all-cause mortality in individuals with evening chronotypes, also regardless of sleep duration [35]. Differed from the two researches above, the
interactive effects between sleep duration and chronotypes on cardiovascular risk factors were examined. As showed by the results, long sleep duration combined with evening preference had the highest prevalence for all five cardiovascular risk factors [40].

We also found that AMI onset time was influenced by chronotype. It has been reported that AMI incidence peaks in the morning among patients with morning chronotypes and in the afternoon among patients with evening chronotypes [17]. A large body of studies have focused on the circadian patterns of AMI onset, but the effects of chronotypes on AMI risk have received little attention. Our results showed that late sleeping was associated with a higher risk of AMI, which was not hard to understand from the two sides. On the one hand, circadian misalignment influences AMI onset through regulating heart rate, blood pressure, epinephrine and cortisol [41], platelet aggregability [42], and vascular resistance [43]. Compared to morning chronotypes, evening chronotypes are associated with higher resting heart rate, blood pressure, epinephrine and cortisol, all contributing to the occurrence of AMI [38, 44]. On the other hand, people with evening chronotypes have a higher possibility of tobacco use, physical inactivity, obesity and less fruit and vegetables consumption [40]. What’s more, late sleeping may raise triglyceride and low-density lipoprotein and lower high-density lipoprotein, thus increasing the risk of AMI [45].

The elderly usually need light when they get up at night, in order to avoid falling down. Due to the more elderly people in the control group, the level 3 of LAN, rather than level 4, was correlated with reduced risk of AMI. Poor sleep quality may increase the risk of CAD [10]. We got the opposite result, probably because more elderly people were enrolled in the control group. Previous study pointed that poor sleep quality was highly prevalent among the elderly Chinese [46]. In the group with age < 65 years, daytime napping seemed to be a protective factor. The sleep duration in this population is shorter, compared with the elderly, but daytime napping can offer rich benefits.

Several limitations should be noted in our study. First, compared with our questionnaire survey, some sleep measurement tools, like polysomnography, will be more objective but costly. Second, the sample size of this study is relatively small and the majority of enrolled subjects are men. Therefore, the results may not be suitable for the whole population, especially in women with AMI. Third, although patients with history of sleep apnea were excluded, we cannot eliminate the influence of snoring on our results absolutely.

**Conclusions**

Late sleep timing (24:00 and after) is an important risk factor for AMI. Daytime napping may protect the population aged < 65 years. Our results are meaningful and helpful for people to cultivate good habits of sleeping, consequently playing a role in preventing cardiovascular disease.

**Abbreviations**
AMI, acute myocardial infarction; CAD, coronary artery disease; SFQ, sleep factors questionnaire; ECG, electrocardiogram; BMI, body mass index; LAN, light at night; ORs, odds ratios; CIs, confidence intervals; ACEI, angiotensin converting enzyme inhibitor; ARB, angiotensin receptor blocker.

LAN, light at night; ORs, odds ratios; CIs, confidence intervals.

They could read comfortably; b They could barely read; c They could see only the hazy outline of the bedroom; d Participants wore a mask to keep out light or they could not see their hand in front of their face; e Adjusted for age, sex, BMI, residence, education level, history of diabetes, hypertension and dyslipidemia, history of coronary artery disease, use of statins, antiplatelet agents, β-blockers, ACEI or ARB, smoking, drinking, diet and regular exercise; f Adjusted for age, sex, BMI, residence, education level, history of diabetes, hypertension and dyslipidemia, history of coronary artery disease, use of statins, antiplatelet agents, β-blockers, ACEI or ARB, smoking, drinking, diet and regular exercise, and adjusted mutually for other sleep factors including timing of sleep and morning waking, sleep duration, sleep quality, insomnia frequency, sleep medication use, LAN, frequency of night-time waking, night work, daytime napping and sleep noise.

**Supplement Table**

**Supplement Table 1** Demographic characteristics comparisons between AMI and CAD groups and non-CAD groups
| Variables                              | AMI group (n=314) | Control group (n=559) | P Value |
|----------------------------------------|------------------|------------------------|---------|
|                                       |                  | CAD group (n=395) | Non-CAD group (n=164) |        |
| Age (years)                            |                  |                       |         |
|                                       | 59 (51, 68)      | 64 (55, 70)          | 60 (53, 66) | 0.001 | 0.898 |
| Men (n, %)                             | 250 (79.6%)      | 276 (69.9%)          | 85 (51.8%) | 0.003 | 0.001 |
| BMI (kg/m²)                            | 25.1 (22.8, 27.0)| 24.6 (22.9, 27.1)   | 24.4 (22.4, 26.9) | 0.793 | 0.250 |
| Residence in cities (n, %)             | 239 (76.1%)      | 277 (70.1%)          | 116 (70.7%) | 0.089 | 0.226 |

**Education level (n, %)**

| Illiterate                             | 40 (12.7%)       | 76 (19.3%)           | 40 (24.4%) | 0.007 | 0.006 |
| Elementary school                      | 58 (18.4%)       | 100 (25.3%)          | 38 (23.2%) |
| Junior high school                     | 101 (32.2%)      | 100 (25.3%)          | 40 (24.4%) |
| Senior high school and technical       | 63 (20.1%)       | 72 (18.2%)           | 26 (15.9%) |
| secondary school                       |                  |                       |         |
| Junior college or above                | 52 (16.6%)       | 47 (11.9%)           | 20 (12.2%) |
| Diabetes (n, %)                         | 54 (17.2%)       | 99 (25.1%)           | 20 (12.2%) | 0.013 | 0.183 |
| Hypertension (n, %)                    | 165 (52.5%)      | 261 (66.1%)          | 79 (48.2%) | 0.001 | 0.387 |
| Dyslipidemia (n, %)                    | 20 (6.4%)        | 22 (5.6%)            | 6 (3.7%) | 0.749 | 0.289 |
| Family history of CAD (n, %)           | 15 (4.8%)        | 14 (3.5%)            | 2 (1.2%) | 0.449 | 0.066 |
| Statins (n, %)                         | 11 (3.5%)        | 25 (6.3%)            | 8 (4.9%) | 0.120 | 0.468 |
| Antiplatelet agents (n, %)             | 21 (6.7%)        | 38 (9.6%)            | 13 (7.9%) | 0.173 | 0.708 |
| β-blockers (n, %)                      | 13 (4.1%)        | 33 (8.4%)            | 9 (5.5%) | 0.031 | 0.499 |
| ACEI or ARB (n, %)                     | 54 (17.2%)       | 123 (31.1%)          | 31 (18.9%) | 0.001 | 0.706 |

**Smoking (n, %)**

| Never                                  | 102 (32.5%)      | 173 (43.8%)          | 103 (62.8%) | 0.001 | 0.001 |
|                | Former  | 69 (17.5%) | 13 (7.9%) |
|----------------|---------|------------|-----------|
| <20 cigarettes/day | 46 (14.6%) | 51 (12.9%) | 15 (9.1%) |
| ≥20 cigarettes/day | 136 (43.3%) | 102 (25.8%) | 33 (20.1%) |

### Drinking (n, %)

|                          | Former  | CAD  | Non-CAD |
|--------------------------|---------|------|---------|
| No                       | 154 (49.0%) | 234 (59.3%) | 115 (70.1%) |
| 1 to 3 times a month     | 65 (20.7%) | 66 (16.7%) | 22 (13.4%) |
| 1 to 6 times a week      | 47 (15.0%) | 42 (10.6%) | 16 (9.8%) |
| At least once a day      | 48 (15.3%) | 53 (13.4%) | 11 (6.7%) |

### Diet (n, %)

|                        | Former  | CAD  | Non-CAD |
|------------------------|---------|------|---------|
| Low-fat diet           | 9 (2.9%) | 27 (6.8%) | 22 (13.4%) |
| Normal diet            | 183 (58.3%) | 245 (62.0%) | 122 (74.4%) |
| High-fat diet          | 122 (38.8%) | 123 (31.2%) | 20 (12.2%) |

### Regular exercise (n, %)

|                         | Former  | CAD  | Non-CAD |
|-------------------------|---------|------|---------|
| 85 (27.1%)              | 143 (36.2%) | 57 (34.8%) |

AMI, acute myocardial infarction; CAD, coronary artery disease; BMI, body mass index; ACEI, Angiotensin Converting Enzyme Inhibitor; ARB, Angiotensin Receptor Blocker.

a AMI compared with CAD group; b AMI compared with non-CAD group.
