Abstract

A classical result in the theory of Hopf algebras concerns the uniqueness and existence of integrals: for an arbitrary Hopf algebra, the integral space has dimension ≤ 1, and for a finite dimensional Hopf algebra, this dimension is exactly one. We generalize these results to quasi-Hopf algebras and dual quasi-Hopf algebras. In particular, it will follow that the bijectivity of the antipode follows from the other axioms of a finite dimensional quasi-Hopf algebra. We give a new version of the Fundamental Theorem for quasi-Hopf algebras. We show that a dual quasi-Hopf algebra is co-Frobenius if and only if it has a non-zero integral. In this case, the space of left or right integrals has dimension one.

0 Introduction

Quasi-bialgebras and quasi-Hopf algebras were introduced by Drinfeld in [10], in connection with the Knizhnik-Zamolodchikov system of partial differential equations, cf. [14]. From a categorical point of view, the notion is not so different from classical bialgebras: we consider an algebra \( H \), and we want to make the category of \( H \)-modules, equipped with the tensor product of vector spaces, into a monoidal category. If we require that the associativity constraint is the natural associativity condition for vector spaces, then we obtain a bialgebra structure on \( H \), in general, we obtain a quasi-bialgebra structure, that is, we have a comultiplication and a counit on \( H \), where the comultiplication is not necessarily coassociative, but only quasi-coassociative.

Of course the theory of quasi-bialgebras and quasi-Hopf algebras is technically more complicated than the classical Hopf algebra theory. A more conceptual difference however, is the fact that the definition of a bialgebra is self-dual, and this symmetry is broken when we pass to quasi-bialgebras. As a consequence, we don’t have the notion of comodule or Hopf module over a quasi-Hopf algebra, and results in Hopf algebras that depend on these notions cannot be generalized in a straightforward way. For instance, the classical proof of the uniqueness and existence of integral is based on the Fundamental Theorem for Hopf modules [24].

Hausser and Nill [13] proved that a finite dimensional quasi-Hopf algebra is a Frobenius algebra, and has a one dimensional integral space. Independently, Panaite and Van Oystaeyen [19] proved the existence of integrals for finite dimensional quasi-Hopf algebras, using the approach developed in [26], without using quasi-Hopf bimodules.

†This paper was written while the first author was visiting the Vrije Universiteit Brussel, and he would like to thank VUB for its warm hospitality.
For a finite dimensional Hopf algebra $H$, it follows from the Fundamental Theorem that $f_H^* \otimes H^*$ and $H$ are isomorphic as Hopf modules. In Section 2, we will see that the isomorphism survives as a left $H$-linear isomorphism in the case of a finite dimensional quasi-Hopf algebra. The method of proof is quite different from the classical one: the isomorphism is constructed explicitly, using the projection of $H$ onto the integral space constructed in [19]. In Drinfeld’s original definition [10], the antipode of a quasi-Hopf algebra is required to be bijective. Actually our proof of $f_H^* \otimes H^* \cong H$ does not use this bijectivity, and has as a consequence that, for a finite dimensional quasi-Hopf algebra, the bijectivity of the antipode follows from the other axioms; another consequence is that the integral space is one-dimensional. In a recent preprint [22], Schauenburg gave a different proof of the fact that the antipode of a finite dimensional quasi-Hopf Hopf algebra is bijective.

The infinite dimensional case is treated as well. We show that a quasi-Hopf algebra (without the assumption that the antipode is bijective) is finite dimensional if and only if the antipode is bijective and the integral space is non-zero. The integral space of an infinite dimensional quasi-Hopf algebra with bijective antipode is zero. A semisimple Hopf algebra with bijective antipode is finite dimensional.

Hauser and Nill [13] also introduced cointegrals on a finite dimensional quasi-Hopf algebra; these cointegrals are elements of the dual space $H^*$, and, using a Structure Theorem for quasi-Hopf bimodules, Hauser and Nill prove that the space of cointegrals $L$ is one-dimensional, and that all non-zero integrals are nondegenerate. In Section 3, we further investigate cointegrals. In [13], it is asked whether there is a connection between the projection of $H$ onto the space of integrals from [19], and the projection of $H^*$ onto the space of cointegrals, introduced in [13]. This is done in Lemma 3.2, and, as an application, we give some characterizations of cointegrals, see Proposition 3.4.

In the second part of Section 3, we propose an alternative definition of the space of coinvariants of a quasi-Hopf bimodule. This alternative space of coinvariants is isomorphic to the Hauser-Nill space of coinvariants, and can be used to give a second version of the Structure Theorem. Our alternative has nevertheless two advantages, compared to the Hauser-Nill approach: first, it is invariant under the adjoint action (cf. Lemma 3.6). Secondly, in the finite dimensional case, it gives rise to an alternative definition of cointegral: we take the alternative coinvariants of $H^*$. If we write down this formula explicitly, we obtain a formula that still makes sense in the infinite dimensional case, so we obtain a plausible definition for cointegrals in the infinite dimensional case.

As we have already pointed out, the definition of quasi-Hopf algebra is not self-dual. Actually, we can introduce dual quasi-Hopf algebras, these are coalgebras, with a multiplication that is not associative, but only quasi-associative. In Section 4 we introduce integrals in dual quasi-Hopf algebras. We were able to prove that the rational dual of a dual quasi-Hopf algebra $A$ is isomorphic as a comodule to the tensor product of $A$ itself and the integral space. This generalizes the classical statement for Hopf algebras (see [24]), but, again, we have to give a direct proof, and cannot deduce the statement from a Structure Theorem. As in the classical case, it then follows immediately that the integral space is zero if and only if the rational dual is zero. Also we can use the integrals to investigate properties of a dual quasi-Hopf algebra $A$ as a coalgebra (Theorem 4.5). The existence of a non-zero integral is equivalent to $A$ being a co-Frobenius coalgebra, a QcF coalgebra, or a left semiperfect coalgebra. Moreover, for a dual quasi-Hopf algebra, all these notions are left-right symmetric. Furthermore the existence of a non-zero integral is equivalent to $A$ being a generator or a projective object in the category of (left or right) comodules.

As a first application of this coalgebraic viewpoint, we find that a dual quasi-Hopf subalgebra of a dual quasi-Hopf algebra with non-zero integral has non-zero integrals. Secondly, it follows that non-zero integrals are unique up to multiplication by a scalar. Also we can give the connection between left and right integrals (Proposition 4.9), and this generalizes [1, Proposition 1.3]. We were able to prove that the antipode of a dual quasi-Hopf algebra with a non-zero integral is injective, but it remains open if it is also surjective, as it is the case for a classical Hopf algebra, see [20]. Our final result is Maschke’s Theorem.
for dual quasi-Hopf algebras (Theorem 4.10), stating that a dual quasi-Hopf algebra is cosemisimple if
and only there exists an integral \( T \) such that \( T(1) = 1 \).

When we pass from bialgebras and Hopf algebras to quasi-bialgebras and quasi-Hopf algebras, the
appearance of the reassociator and the elements \( \alpha \) and \( \beta \) in the definition of the antipode, considerably
increase the complexity of computations and proofs. This observation is not new, other authors who
have been working on quasi-Hopf algebras experienced this before us. However, the philosophy is ba-
sically the same as in the case of usual bialgebras: the idea is to make the category of \( A \)-modules into a
monoidal category. Recently, Schauenburg proposed an alternative approach to proving results on quasi-
bialgebras, exploiting the categorical ideas behind quasi-bialgebras, and replacing the computational
arguments using the Sweedler notation by conceptual arguments (see [22] for detail). At this moment
is not clear to us whether Schauenburg’s ideas can be used to give alternative and/or more transparant
proofs of the results in this paper.

1 Preliminaries

We work over a commutative field \( k \). All algebras, linear spaces etc. will be over \( k \); unadorned \( \otimes \) means
\( \otimes_k \). Following Drinfeld \([11]\), a quasi-bialgebra is a four-tuple \( (H, \Delta, \varepsilon, \Phi) \) where \( H \) is an associative
algebra with unit, \( \Phi \) is an invertible element in \( H \otimes H \otimes H \), and \( \Delta : H \to H \otimes H \) and \( \varepsilon : H \to k \) are
algebra homomorphisms satisfying the identities

\[
(id \otimes \Delta)(\Delta(h)) = \Phi(\Delta \otimes id)(\Delta(h))\Phi^{-1}, \tag{1.1}
\]

\[
(id \otimes \varepsilon)(\Delta(h)) = h \otimes 1, \quad (\varepsilon \otimes id)(\Delta(h)) = 1 \otimes h, \tag{1.2}
\]

for all \( h \in H \), and \( \Phi \) has to be a 3-cocycle, in the sense that

\[
(1 \otimes \Phi)(id \otimes \Delta \otimes id)(\Phi)(\Phi \otimes 1) = (id \otimes id \otimes \Delta)(\Phi)(\Delta \otimes id \otimes id)(\Phi), \tag{1.3}
\]

\[
(id \otimes \varepsilon \otimes id)(\Phi) = 1 \otimes 1 \otimes 1. \tag{1.4}
\]

The map \( \Delta \) is called the coproduct or the comultiplication, \( \varepsilon \) the counit and \( \Phi \) the reassociator. As for
Hopf algebras we denote \( \Delta(h) = \sum h_1 \otimes h_2 \), but since \( \Delta \) is only quasi-coassociative we adopt the further
convention

\[
(\Delta \otimes id)(\Delta(h)) = \sum h_{(1,1)} \otimes h_{(1,2)} \otimes h_2, \quad (id \otimes \Delta)(\Delta(h)) = \sum h_1 \otimes h_{(2,1)} \otimes h_{(2,2)},
\]

for all \( h \in H \). We will denote the tensor components of \( \Phi \) by capital letters, and the ones of \( \Phi^{-1} \) by small
letters, namely

\[
\Phi = \sum X^1 \otimes X^2 \otimes X^3 = \sum T^1 \otimes T^2 \otimes T^3 = \sum V^1 \otimes V^2 \otimes V^3 = \ldots
\]

\[
\Phi^{-1} = \sum x^1 \otimes x^2 \otimes x^3 = \sum t^1 \otimes t^2 \otimes t^3 = \sum v^1 \otimes v^2 \otimes v^3 = \ldots
\]

\( H \) is called a quasi-Hopf algebra if, moreover, there exists an anti-automorphism \( S \) of the algebra \( H \) and
elements \( \alpha, \beta \in H \) such that, for all \( h \in H \), we have:

\[
\sum S(h_1) \alpha h_2 = \varepsilon(h) \alpha \quad \text{and} \quad \sum h_1 \beta S(h_2) = \varepsilon(h) \beta, \tag{1.5}
\]

\[
\sum X^1 \beta S(X^2) \alpha X^3 = 1 \quad \text{and} \quad \sum S(x^1) \alpha x^2 \beta S(x^3) = 1. \tag{1.6}
\]

For a quasi-Hopf algebra the antipode is determined uniquely up to a transformation \( \alpha \mapsto U\alpha \), \( \beta \mapsto \beta U^{-1} \), \( S(h) \mapsto US(h)U^{-1} \), where \( U \in H \) is invertible. The axioms for a quasi-Hopf algebra imply that
\( \varepsilon(\alpha)\varepsilon(\beta) = 1 \), so, by rescaling \( \alpha \) and \( \beta \), we may assume without loss of generality that \( \varepsilon(\alpha) = \varepsilon(\beta) = 1 \) and \( \varepsilon \circ S = \varepsilon \). The identities (1.2), (1.3) and (1.4) also imply that

\[
(\varepsilon \otimes \text{id} \otimes \text{id})(\Phi) = (\text{id} \otimes \text{id} \otimes \varepsilon)(\Phi) = 1 \otimes 1 \otimes 1.
\] (1.7)

Next we recall that the definition of a quasi-Hopf algebra is “twist coinvariant” in the following sense. An invertible element \( F \in H \otimes H \) is called a gauge transformation or twist if \( (\varepsilon \otimes \text{id})(F) = (\text{id} \otimes \varepsilon)(F) = 1 \). If \( H \) is a quasi-Hopf algebra and \( F = \sum F^1 \otimes F^2 \in H \otimes H \) is a gauge transformation with inverse \( F^{-1} = \sum G^1 \otimes G^2 \), then we can define a new quasi-Hopf algebra \( H_F \) by keeping the multiplication, unit, counit and antipode of \( H \) and replacing the comultiplication, antipode and the elements \( \alpha \) and \( \beta \) by

\[
\Delta_F(h) = F \Delta(h) F^{-1},
\]

\[
\Phi_F = (1 \otimes F)(id \otimes \Delta)(F)\Phi(\Delta \otimes id)(F^{-1}) (F^{-1} \otimes 1),
\]

\[
\alpha_F = \sum S(G^1)\alpha G^2, \quad \beta_F = \sum F^1 \beta S(F^2).
\] (1.10)

It is well-known that the antipode of a Hopf algebra is an anti-coalgebra morphism. For a quasi-Hopf algebra, we have the following statement: there exists a gauge transformation \( f \in H \otimes H \) such that

\[
f\Delta(S(h))f^{-1} = \sum (S \otimes S)(\Delta^{op}(h)), \quad \text{for all } h \in H.
\] (1.11)

\( f \) can be computed explicitly. First set

\[
\sum A^1 \otimes A^2 \otimes A^3 \otimes A^4 = (\Phi \otimes 1)(\Delta \otimes id \otimes id)(\Phi^{-1}),
\]

\[
\sum B^1 \otimes B^2 \otimes B^3 \otimes B^4 = (\Delta \otimes id \otimes id)(\Phi)(\Phi^{-1} \otimes 1)
\] (1.13)

and then define \( \gamma, \delta \in H \otimes H \) by

\[
\gamma = \sum S(A^2) \alpha A^3 \otimes S(A^1) \alpha A^4 \quad \text{and} \quad \delta = \sum B^1 \beta S(B^4) \otimes B^2 \beta S(B^3).
\] (1.14)

\( f \) and \( f^{-1} \) are then given by the formulas

\[
f = \sum (S \otimes S)(\Delta^{op}(x^1))\gamma \Delta(x^2 \beta S(x^3)),
\]

\[
f^{-1} = \sum \Delta(S(x^1)\alpha x^2)\delta \Delta(S \otimes S)(\Delta^{op}(x^3))
\] (1.16)

where \( \Delta^{op}(h) = \sum h_2 \otimes h_1 \). \( f \) satisfies the following relations:

\[
f \Delta(\alpha) = \gamma, \quad \Delta(\beta) f^{-1} = \delta.
\] (1.17)

Furthermore the corresponding twisted reassociator (see [13]) is given by

\[
\Phi_f = \sum (S \otimes S \otimes S)(X^3 \otimes X^2 \otimes X^1).
\] (1.18)

In a Hopf algebra \( H \), we obviously have the identity

\[
\sum h_1 \otimes h_2 S(h_3) = h \otimes 1, \quad \text{for all } h \in H.
\]

We will need the generalization of this formula to quasi-Hopf algebras. Following [14], [15], we define

\[
p_R = \sum p^1 \otimes p^2 = \sum x^1 \otimes x^2 \beta S(x^3), \quad q_R = \sum q^1 \otimes q^2 = \sum X^1 \otimes S^{-1}(\alpha X^3) X^2.
\] (1.19)
For all \( h \in H \), we then have
\[
\sum \Delta(h_1)p_R[1 \otimes S(h_2)] = p_R[h \otimes 1], \quad \sum[1 \otimes S^{-1}(h_2)]q_R\Delta(h_1) = (h \otimes 1)q_R, \tag{1.20}
\]
and
\[
\sum \Delta(q^1)p_R[1 \otimes S(q^2)] = 1 \otimes 1, \quad \sum[1 \otimes S^{-1}(p^2)]q_R\Delta(p^1) = 1 \otimes 1, \tag{1.21}
\]
\[
(q_R \otimes 1)(\Delta \otimes id)(q_R)\Phi^{-1} - \sum[1 \otimes S^{-1}(X^3) \otimes S^{-1}(X^2)][1 \otimes S^{-1}(f^2) \otimes S^{-1}(f^1)](id \otimes \Delta)(q_R\Delta(X^1)), \tag{1.22}
\]
\[
\Phi(\Delta \otimes id)(p_R)(p_R \otimes id) - \sum(id \otimes \Delta)(\Delta(x^1)p_R)(1 \otimes f^{-1})(1 \otimes S(x^3) \otimes S(x^2)), \tag{1.23}
\]
where \( f = \sum f^1 \otimes f^2 \) is the twist defined in (1.15). Note that the formulas (1.16, 1.23) (except (1.22) and the second part of (1.20-1.21)) can be proved without using the bijectivity of the antipode \( S \).

2 Integrals in quasi-Hopf algebras

Let \( H \) be a finite dimensional quasi-Hopf algebra with an antipode \( S \). In [13], it is shown that \( H \) is a Frobenius algebra and, as a consequence, the space of left (right) integrals in \( H \) is one dimensional. The proof in [13] relies on the fact that the antipode \( S \) is bijective. Using different arguments independent of the bijectivity of the antipode, we will give another proof of the existence and uniqueness of integrals in \( H \). In fact we will prove that, in the definition of finite dimensional quasi-Hopf algebra, the bijectivity of the antipode can be dropped, in other words, the bijectivity of the antipode follows from the other axioms. This will generalize a similar result for Hopf algebras, see [16].

Let us make our terminology consistent: by a quasi-Hopf algebra, we will mean a quasi-Hopf algebra as defined in Section 1, but without the assumption that the antipode is bijective. If the antipode is bijective, then we will say that we have a quasi-Hopf algebra in the sense of Drinfeld. With this convention, our main result is the following: a finite dimensional quasi-Hopf algebra is a quasi-Hopf algebra in the sense of Drinfeld.

Recall that \( t \in H \) is called a left (resp. right) integral in \( H \) if \( ht = \varepsilon(h)t \) (resp. \( th = \varepsilon(h)t \)), \( \forall h \in H \). We denote by \( \int^H \) (\( \int_r^H \)) the space of left (right) integrals in \( H \). If there exists a non-zero left integral in \( H \) which is at the same time a right integral, then \( H \) is called unimodular.

In [16], the Fundamental Theorem is used to prove the existence and uniqueness of integrals, and then the bijectivity of the antipode follows. In the quasi-Hopf algebra case, this approach will not work, since we cannot define Hopf modules. Van Daele [24] gave a short and direct proof of the existence and uniqueness of integrals in a finite dimensional Hopf algebra, and Panaite and Van Oystaeyen [19] generalized Van Daele’s argument, proving the existence of left integrals in finite dimensional quasi-Hopf algebras. More precisely, let \( H \) be a finite dimensional quasi-Hopf algebra, \( \{e_i\}_{i=1}^n \) a basis of \( H \) and \( \{e^i\}_{i=1}^n \) the dual basis of \( H^* \). Following [19] we define
\[
P(h) = \sum_{i=1}^n \langle e^i, \beta S(S(2e_i)\alpha X^3)h \rangle X^1(e_i), \tag{2.1}
\]
for all \( h \in H \). Then one can show that \( P(h) \in \int^H \), \( \forall h \in H \) and \( \sum_{i=1}^n \langle e^i, S(P(e_i)\beta) \rangle = \varepsilon(\beta) = 1 \). It follows that at least one of the \( P(e_i) \neq 0 \), and \( \int^H \neq 0 \).

In order to prove the uniqueness of integrals for finite dimensional quasi-Hopf algebras we need the following
Lemma 2.1 Let $t$ be a left integral in a quasi-Hopf algebra $H$. Then for all $h \in H$

\[
\sum hX^1t_1 \otimes S(X^2t_2)\alpha X^3 = \sum X^1t_1 \otimes S(X^2t_2)\alpha X^3h, \tag{2.2}
\]

and

\[
\sum t_1 \otimes S(t_2) = \sum X^1t_1 \otimes S(X^2t_2)\alpha X^3 = \sum \beta X^1t_1 \otimes S(X^2t_2)\alpha X^3. \tag{2.3}
\]

Proof. For all $h \in H$ we calculate, using (1.5), (1.1) and $t \in \mathfrak{f}_l^H$ that

\[
\sum hX^1t_1 \otimes S(X^2t_2)\alpha X^3 = \sum h_1X^1t_1 \otimes S(h_{(2,1)}X^2t_2)\alpha h_{(2,2)}X^3
\]

\[
= \sum X^1(h_1t_1) \otimes S(X^2(h_1t_2))\alpha X^3h_2 = \sum X^1t_1 \otimes S(X^2t_2)\alpha X^3h.
\]

To prove the first equality in (2.3), we take $\sum X^1t_1 \otimes S(X^2t_2)\alpha X^3$. First we apply the 3-cocycle condition

\[
\Phi \otimes 1 = (id \otimes \Delta \otimes id) (\Phi^{-1})(1 \otimes id \otimes \Delta) (\Phi) (\Delta \otimes id \otimes id)(\Phi)
\]

and then, successively using the fact that $t \in \mathfrak{f}_l^H$, (1.5), (1.4), (1.7) and (1.6), we find the left hand side of (2.3). The second equality in (2.3) follows from (2.2).

For a quasi-Hopf algebra $H$, we introduce $H^*$ as the dual space of $H$ with its natural multiplication $\langle h^*g^*,h \rangle = \sum h^*_b h^a g^b h^c$, where $h^*,g^* \in H^*$ and $h \in H$. If $H$ is finite dimensional, then $H^*$ is also equipped with a natural coassociative coalgebra structure $(\tilde{\Delta},\tilde{\varepsilon})$ given by $\langle \tilde{\Delta}(h^*),h \otimes h' \rangle = \langle h^*,hh' \rangle$ and $\tilde{\varepsilon}(h^*) = h^*(1)$, where $h^*,h,h' \in H$ and $(\cdot,\cdot): H^* \otimes H \rightarrow k$ denotes the dual pairing. On $H^*$ we have the natural left and right $H$-actions

\[
\langle h \rightarrow h^*,h' \rangle = \langle h^*,h'h \rangle, \quad \langle h^* \leftarrow h,h' \rangle = \langle h^*,hh' \rangle, \tag{2.4}
\]

where $h,h' \in H$ and $h^* \in H^*$. This makes $H^*$ into a $H\mathcal{H}$-bimodule.

We also introduce $\tilde{S}: H^* \rightarrow H^*$ as the anti-coalgebra homomorphism dual to $S$, i.e. $\langle \tilde{S}(h^*),h \rangle = \langle h^*,S(h) \rangle \forall h^* \in H^*, h \in H$.

Theorem 2.2 Let $H$ be a finite dimensional quasi-Hopf algebra, $\{e_i\}_{i=1}^n$ a basis of $H$ with dual basis $\{e^i\}_{i=1}^n$ of $H^*$, and define $\theta: \mathfrak{f}_l^H \otimes H^* \rightarrow H$, by

\[
\theta(t \otimes h^*) = \sum h^*(S(X^2t_2p^3)\alpha X^3)X^1t_1p^1, \quad \forall t \in \mathfrak{f}_l^H, h^* \in H^*, \tag{2.5}
\]

where $p_R = \sum p^1 \otimes p^2$ is the element defined in (1.19). Then the following assertions hold:

(i) $\theta$ is an isomorphism of left $H$-modules, where $\mathfrak{f}_l^H \otimes H^*$ is a left $H$-modules via $h \cdot (t \otimes h^*) = t \otimes h \rightarrow h^*$ $\forall h \in H, t \in \mathfrak{f}_l^H, h^* \in H^*$, and $H$ is a left $H$-module via left multiplication. Consequently $\dim_k \mathfrak{f}_l^H = 1$.

The inverse of $\theta$ is given by

\[
\theta^{-1}(h) = \sum_{i=1}^nP(e_ih) \otimes e^i, \quad \forall h \in H, \tag{2.6}
\]

where $P$ is the projection onto the space of left integrals, defined in (2.7).

(ii) The antipode $S$ is bijective.

(iii) $S(\mathfrak{f}_l^H) = \mathfrak{f}_r^H, S(\mathfrak{f}_r^H) = \mathfrak{f}_l^H, \text{ and } \dim_k \mathfrak{f}_r^H = 1$. 

6
Proof. (i) First we show that $\theta$ and $\theta^{-1}$ are inverses. Indeed, for all $h \in H$ we have:

$$\theta(\theta^{-1}(h)) = \sum_{i,j=1}^{n} \langle e^j, \beta S(Y^2 X^2 e_j) \alpha X^3 \rangle e_i h \langle e^i, S(Y^2 X^3 e_i) \alpha Y^3 \rangle$$

$$Y^1 X^1_1(e_i) \langle e_i, l_p \rangle$$

$$= \sum_{i,j=1}^{n} \langle e^j, \beta S(Y^2 X^2_1) p_2^1 S(Y^2_2 \alpha X^3) \alpha Y^3 \rangle h \langle e^i, Y^1 X^1_1 \rangle p_1^1 e_j$$

$$= \sum Y^1 x^1 Z^1 \beta S(Y^2 x^2 X^1 Z_1^1 \beta S(x^3 X^2_2) \alpha x^3 Z^2_1) \alpha Y^3 h$$

$$\sum Y^1 \beta S(Y^2 X^1 \beta S(Y^2) \alpha X^3) \alpha Y^3 h = h.$$ 

For all $t \in f^H_1$ and $h^* \in H^*$ we compute

$$\theta^{-1}(\theta(t \otimes h^*)) = \sum_{i=1}^{n} h^*(S(X^2 t_2^2 p^2) \alpha X^3) P(e_i, X^1 t_1 p^1) \otimes e^i$$

$$\sum_{i,j=1}^{n} h^*(S(Y^2 t_2^1 p^2) \alpha X^3 \beta S(Y^2(e_j) \alpha Y^3) e_i) \langle e_i, X^1 t_1 p^1 \rangle Y^1 Y_1(e_j) \otimes e^i$$

$$\sum_{i=1}^{n} h^*(S(Y^2 p^2_1) \alpha Y^3 \beta S(Y^1 x^3) e_i) t Y^1 p_1 \otimes e^i$$

$$\sum_{i=1}^{n} h^*(S(Y^3 x^2 X^3 \beta S(y^3 x^3) e_i) t Y^1 X^1 \otimes e^i$$

$$\sum_{i=1}^{n} h^*(S(Y^3 x^1) \alpha x^2 \beta S(x^3) e_i) t \otimes e^i$$

$$\sum_{i=1}^{n} h^*(e_i) t \otimes e^i = t \otimes h^*.$$

Since $\theta$ is a bijection and $\dim H = \dim H^*$ is finite, it follows that $\dim f^H_1 = 1$. We are left to show that $\theta$ is $H$-linear. For all $h \in H$, $t \in f^H_1$ and $h^* \in H^*$ we have:

$$h \theta(t \otimes h^*) = \sum h^*(S(X^2 t_2^2 p^2) \alpha X^3) h X^1 t_1 p^1$$

$$= \sum \langle h^*, S(X^2 t_2^2 p^2) \alpha X^3 \rangle h X^1 t_1 p^1$$

$$= \theta(t \otimes h \rightarrow h^*).$$

(ii) First we prove that $\overline{S}$ is bijective. $H^*$ is finite dimensional, so it suffices to show that $\overline{S}$ is injective. Let $h^* \in H^*$ be such that $\overline{S}(h^*) = 0$, and take $0 \neq t \in f^H_1$. For all $h \in H$ we have

$$\theta(t \otimes \beta S(h) \rightarrow h^*) = \langle \beta S(h) \rightarrow h^*, S(X^2 t_2^2) \alpha X^3 \rangle X^1 t_1 p^1$$

$$= \sum \langle h^*, S(X^2 t_2^2) \alpha X^3 \beta S(h) \rangle X^1 t_1 p^1$$

$$= \sum \langle h^*, S(h t_2^2) \rangle t_1 p^1$$

$$= \sum \langle \overline{S}(h^*), h t_2^2 \rangle t_1 p^1 = 0.$$

Since $\theta$ is bijective we obtain that $t \otimes \beta S(h) \rightarrow h^* = 0$. Now, because $t \neq 0$ and $\dim f^H_1 = 1$, it follows that $\beta S(h) \rightarrow h^* = 0$, for all $h \in H$. Therefore, by (1.3), for all $h' \in H$ we have

$$h^*(h') = \sum \langle h^*, h' S(x^1) \alpha x^2 \beta S(x^3) \rangle = \sum \langle \beta S(x^3) \rightarrow h^*, h' S(x^1) \alpha x^2 \rangle = 0.$$
It is not hard to see that $\overline{S} : H^* \to H^{**}$, $\overline{S}(h^*) = h^{**} \circ \overline{S}$, $\forall h^{**} \in H^{**}$, is a bijective map. If we define $\xi : H \to H^{**}$ by $\xi(h^*) = h^*(h)$, $\forall h \in H, h^* \in H^*$, then we can easily show that $\{\xi(e_i)\}_{i=1}^{\infty}$ is a basis of $H^{**}$ dual to the basis $\{e_i\}_{i=1}^{\infty}$ of $H^*$, and it follows that $\xi$ is bijective. Moreover, $\xi^{-1}$ is given by

$$\xi^{-1}(h^{**}) = \sum_{i=1}^{n} h^{**}(e_i) \cdot i, \forall h^{**} \in H^{**}.$$  

In addition, $\xi^{-1} \circ \overline{S} \cdot \xi = S \circ S$ so $S$ is bijective.

(iii) We have already seen that $S$ is an anti-algebra automorphism of $H$ and $\dim_k \int^H = 1$. The rest of the proof is identical to the proof for classical Hopf algebras. $\square$

**Remark 2.3** We cannot deduce the isomorphism $\theta$ in Theorem 2.2 from a Structure Theorem for dual quasi-Hopf bicomodules. If $A$ is a dual quasi-Hopf algebra (for the complete definition see the last Section) then the category of $A$-bicomodules $A \cdot M^A$ is monoidal and $A$ is in a canonical way an algebra in $A \cdot M^A$. Thus, it makes sense to define a right dual quasi-Hopf $A$-bicomodule $M$ as being a right $A$-module in $A \cdot M^A$. Denote by $A \cdot M^A$ the category whose objects are right dual quasi-Hopf $A$-bicomodules and morphisms $A$-bicomodule maps which are also right $A$-linear (for more details see [22]). This definition is dual to the one given by Hauser and Nill [13] for quasi-Hopf bimodules. So, using their Structure Theorem, by duality, we can prove a Structure Theorem for dual quasi-Hopf $A$-bicomodules and then we can apply it in the particular case $M = H$ (here $H$ is a finite dimensional quasi-Hopf algebra and $A = H^*$, the linear dual space of $H$). But, on a hand, in order to obtain $H$ as an object in $H^* \cdot M^H$ we need the antipode $S$ of $H$ to be bijective and, on the other hand, using the definition of Hauser and Nill for coinvariants, in the dual case we don’t obtain the space of integrals in $H$. In consequence, if the isomorphism $\theta$ is derived from a Structure Theorem for dual quasi-Hopf bicomodules then it is not the dual case of Hauser and Nill result.

Now, let $M \in A \cdot M^A$. First, since $A$ is a coassociative coalgebra we can define the set of right coinvariants $M^{co(A)}$ of $M$ as being $M^{co(A)} := \{m \in M | \rho_r(m) = m \otimes 1\}$, where $\rho_r : M \to M \otimes A$, $\rho_r(m) = \sum m_{(0)} \otimes m_{(1)}$, $m \in M$, is the right coaction of $A$ on $M$. Since $\rho_r(m \cdot a) = \rho_r(m)\Delta(a)$ for all $m \in M$ and $a \in A$ (we denote by $M \otimes A \ni m \otimes a \to m \cdot a \in M$, $m \in M$, $a \in A$, the right action of $A$ on $m$), as in [4, Theorem 2.11] we can show that $\overline{\theta} : M \to M^{co(A)}$ given by $\overline{\theta}(m) := \sum m_{(0)} \cdot b(m_{(1)})S(m_{(2)})$, $m \in M$, is well defined and a surjection. Thus, the map $\overline{\theta}^{-1} : M \to M^{co(A)} \otimes A$, $\overline{\theta}^{-1}(m) := \sum \overline{\theta}(m_{(0)}) \otimes m_{(1)}$, $m \in M$, is well defined. It is not hard to see that $M^{co(A)} \otimes A \in A \cdot M^A$ via the structures $(m \otimes a) \cdot b := m \otimes ab$, and $M^{co(A)} \otimes A \ni m \otimes a \to \sum a_1 \otimes m \otimes a_2 \otimes a_3 \in A \otimes M^{co(A)} \otimes A \otimes A$, $m \in M^{co(A)}$, $a, b \in A$. In this way $\overline{\theta}^{-1}$ becomes a right $A$-coassociative map but not a morphism in $A \cdot M^A$; moreover, we don’t know if, in general, $\overline{\theta}^{-1}$ is bijective. Under these circumstances, if we take $H$ a finite dimensional quasi-Hopf algebra then $H \in H^* \cdot M^H$ via

$$H \ni h \to \sum_{i,j=1}^{n} e^i \otimes e_j h e_i \otimes e_j \in H^* \otimes H \otimes H^*,$$

where $\{e_i\}_{i=1}^{\infty}$ is a basis of $H$ with dual basis $\{e^i\}_{i=1}^{\infty}$ of $H^*$. Moreover, if we define

$$h \cdot h^* := \sum h^*(S(X^2 h_2)X h_3 X^2 h_1) \quad \forall h \in H, h^* \in H^*$$

then with these structures $H$ is not an object in $H^* \cdot M^H$ but $\rho_r(h \cdot h^*) = \rho_r(h)\Delta(h^*)$, $H^{co(H^*)} = \int^H$ and the projection $\overline{\theta} : H \to \int^H$ is just the projection $P$ defined in (2.3). Therefore, in this case $\overline{\theta}^{-1}$ coincide with $\overline{\theta}^{-1}$ defined in (2.6), so it is bijective. We notice that, in the proof of the fact that $\overline{\theta}^{-1}$ defined by (2.3) is the inverse of $\theta$, a key role is played by the relation (2.3) in Lemma 2.1. Since the equality (2.3) involve all the structures of $H$ as a quasi-Hopf algebra, it cannot be generalized for the coinvariants $M^{co(A)}$ of a dual quasi-Hopf $A$-bicomodule $M$. In conclusion, in order to obtain $\theta$ from a Structure Theorem for dual quasi-Hopf bicomodules we need the above context but it don’t provide a ”suggestion” for the general
case. Also, the same kind of problems occur when we work with relative Hopf modules \[3\], instead of dual quasi-Hopf bicomodules.

Let \( H \) be a quasi-Hopf algebra and \( t \) a left integral in \( H \). Using the fact that \( H \) is an associative algebra, we find that \( th \) is also a left integral in \( H \), for all \( h \in H \), hence the space of left (right) integral in \( H \) is a two-sided ideal. Moreover, if \( H \) is finite dimensional, then it follows from the uniqueness of the integral in \( H \), that there exists \( \mu \in H^* \) such that

\[
    th = \mu(h)t, \quad \forall t \in \mathcal{H}_t^H \text{ and } h \in H. \tag{2.7}
\]

More precisely, \( \mu \in \text{Alg}(H,k) \). It was noted in \[13\] that \( \text{Alg}(H,k) \) is a group with multiplication given by \( \nu \otimes \xi = (\nu \otimes \xi) \circ \Delta \), unit \( \varepsilon \), and inverse \( \mu^{-1} = \mu \circ S \). In \[13\], \( \mu \) is called the modulus of \( H \), but, following the classical terminology for Hopf algebras, we will call \( \mu \) the distinguished grouplike element. Observe that \( \mu = \varepsilon \) if and only if \( H \) is unimodular. As in the case of a Hopf algebra, it follows from the bijectivity of the antipode that

\[
    hr = \mu^{-1}(h)r = \mu(S(h))r, \quad \forall r \in \mathcal{H}_r^H \text{ and } h \in H. \tag{2.8}
\]

For infinite dimensional Hopf algebras it is well known that the space of left (right) integrals in \( H \) is zero \[24\, \text{pg. 107}\]. In order to prove a similar result for quasi-Hopf algebras we first need a Lemma.

**Lemma 2.4** Let \( H \) be a quasi-Hopf algebra in the sense of Drinfeld and define

\[
    \Delta : H \to H \otimes H, \quad \Delta(h) = \sum h_1 \otimes h_2 := \sum q^1 h_1 p^1 \otimes q^2 h_2 p^2, \quad \forall h \in H, \tag{2.9}
\]

where \( p_R = \sum p^1 \otimes p^2 \) and \( q_R = \sum q^1 \otimes q^2 \) are defined by \(1.19\). If \( J \) is a non-zero two-sided ideal of \( H \) such that \( \Delta(J) \subseteq J \otimes H \), then \( J = H \).

**Proof.** From \(1.21\), we easily deduce that

\[
    \sum (1 \otimes S^{-1}(p^2)) \Delta(p^1 h q^1)(1 \otimes S(q^2)) = \Delta(h), \quad \forall h \in H.
\]

This implies that \( \Delta(J) \subseteq J \otimes H \), since \( J \) is a two-sided ideal of \( H \) and \( \Delta(J) \subseteq J \otimes H \). Now, if \( \varepsilon(J) = 0 \), then for any \( h \in H \) we have \( h = \sum \varepsilon(h_1)h_2 \in \varepsilon(J)H = 0 \), so \( J = 0 \), a contradiction. Thus \( \varepsilon(J) \neq 0 \), and there exists \( a \in J \) with \( \varepsilon(a) = 1 \). Using \(1.6\), we obtain that \( \beta = \varepsilon(a)\beta = \sum a_i \beta S(a_2) \in JH \subseteq J \), so \( \beta \in J \). Using \(1.6\) and the fact that \( J \) is a two-sided ideal of \( H \), we find that \( 1 = \sum X^1 \beta S(X^2)\alpha X^3 \in J \), and \( J = H \).

\( \Box \)

For \( h \in H \) and \( h^* \in H^* \), we define \( h^* \to h = \sum h^*(h_2)h_1 \). For a two-sided ideal \( I \) of \( H \), we let \( H^* \to I \) be the subspace of \( I \) generated by all the elements of the form \( h^* \to a \), with \( h^* \in H^* \) and \( a \in I \).

**Theorem 2.5** Let \( H \) be a quasi-Hopf algebra in the sense of Drinfeld and \( I \) a non-zero two-sided ideal of \( H \). Then

\[
    J = H^* \to I = H.
\]

As a consequence, we obtain

(i) If \( H \) is a quasi-Hopf algebra with an antipode \( S \), then \( H \) is finite dimensional if and only if \( S \) is bijective and \( \mathcal{H}_r^H \neq 0 \).

(ii) If a quasi-Hopf algebra in the sense of Drinfeld is semisimple as an algebra, then it is finite dimensional.
Proof. The statement follows from Lemma 2.4 if we can show that $J$ is a non-zero two-sided ideal of $H$ such that $\Delta(J) \subseteq J \otimes H$.

Obviously $e \to h = h$, and therefore $I \subseteq J$. For all $h \in H$, $h^* \in H^*$ and $a \in I$ we have

$$
(h^* \to a)h = \sum h^*(q^2a_2p^2)q^1a_1p^1h
$$

(1.20)

$$
= \sum h^*(q^2(ah_1)_2p^2S(h_2))q^1(ah_1)_1p^1
$$

$$
= \sum (S(h_2) \to h^*) \to (ah_1)
$$

and $J$ is a right ideal. $J$ is also a left ideal, since

$$
h(h^* \to a) = \sum h^*(q^2a_2p^2)hq^1a_1p^1
$$

(1.20)

$$
= \sum h^*(S^{-1}(h_2)q^2(h_1a)_2p^2)q^1(h_1a)_1p^1
$$

$$
= \sum (h^* \leftarrow S^{-1}(h_2)) \to (h_1a).
$$

Write $f = \sum f^1 \otimes f^2$. Using (1.22), (1.1) and (1.23) we can show that

$$
h^* \to (g^* \to h)
$$

$$
= \sum [(g^1S(x^3) \to h^* \leftarrow S^{-1}(f^2X^3))(g^2S(x^2) \to g^* \leftarrow S^{-1}(f^1X^2))] \to (X^1ax^1)
$$

for all $h^*, g^* \in H^*$ and $h \in H$. $I$ is a two-sided ideal of $H$, so the above equality shows that $H^* \to J \subseteq J$. To prove that $\Delta(J) \subseteq J \otimes H$, we use the same arguments as in [3, p. 12]. Take $a \in J$, and write $\Delta(a) = \sum a_i \otimes a_j$, where $a_1, \ldots, a_m \in J$ and $a_{m+1}, \ldots, a_n$ are linearly independent modulo $J$. For any $h^* \in H^*$, $h^* \to a = \sum n h^*(a'_i) a_i \in J$. The linear independence of $a_{m+1}, \ldots, a_n$ modulo $J$ implies that $h^*(a'_i) = 0$, and therefore $a'_i = 0 (h^*$ is arbitrary), for all $i > m$. We find that $\Delta(a) \in J \otimes H$, as needed.

(i) One implication follows from Theorem 2.3. Conversely, assume that $S$ is bijective and $I = \bigcap H \neq 0$. Then $I$ is a non-zero two-sided ideal of $H$ and the first part of our Theorem tells us that $H^* \to I = H$.

Thus there exist $\{h^*_i\}_{i=1}^n \subseteq H^*$ and $\{t_i\}_{i=1}^n \subseteq J^H$ such that $1 = \sum h^*_i \to t_i$. For any $i = \overline{1,n}$ we have

$$
\Delta(t_i) = \sum_{j=1}^n a'_j \otimes b'_j,
$$

for some $\{a'_j\}_{j=1}^n \subseteq H$ and $\{b'_j\}_{j=1}^n \subseteq H$. Therefore, for any $h^* \in H^*$ and $i = \overline{1,n}$ we have $h^* \to t_i = \sum_{j=1}^m h^*(b'_j)a'_j$. For all $h \in H$ we obtain that

$$
h = \sum_{i=1}^n h(h^*_i \to t_i)
$$

$$
= \sum_{i=1}^n (h^* \leftarrow S^{-1}(h_2)) \to h_1t_i
$$

$$
= \sum_{i=1}^n (h^* \leftarrow S^{-1}(h)) \to t_i \text{ since } t_i \in J^H, \forall i = \overline{1,n}
$$

$$
= \sum_{i=1}^n \sum_{j=1}^n h^*(S^{-1}(h)b'_j) a'_j.
$$

This shows that $H$ is finite dimensional, since it is a subspace of the span of $\{a'_j \mid i = \overline{1,n}, j = \overline{1,m}\}$. 

10
(ii) Let \( H \) be a semisimple quasi-Hopf algebra with bijective antipode. Then \( \ker(\varepsilon) \) is a two-sided ideal of \( H \). Since \( H \) is a semisimple left \( H \)-module, there exists a left ideal \( I \) of \( H \) such that \( H = I \oplus \ker(\varepsilon) \). \( \ker(\varepsilon) \) has codimension 1 in \( H \), hence \( I \) has dimension 1. Write \( 1 = t + h \), with \( t \in I \), \( h \in \ker(\varepsilon) \). \( t \neq 0 \), because \( 1 \not\in \ker(\varepsilon) \). It follows that \( I = kt \), since \( \dim_k(I) = 1 \). For all \( h' \in H \), we have \( h't \in I \), and also \( h't = \varepsilon(h')t + (h' - \varepsilon(h')1)t \) with \( \varepsilon(h')t \in I \) and \( (h' - \varepsilon(h')1)t \in \ker(\varepsilon) \). Since we have a direct sum, it follows that \( h't = \varepsilon(h')t \), and \( t \) is a non-zero left integral in \( H \). From (i), it then follows that \( H \) is finite dimensional. \( \square \)

**Remarks 2.6** (i) Let \( H \) be a quasi-Hopf algebra in the sense of Drinfeld. Then \( S(f^H) = f^H \) and \( \dim_k f^H = \dim_k f'_r \). Therefore, if \( H \) is infinite dimensional then \( f^H = f'_r = 0 \).

(ii) Let \( H \) be a finite dimensional quasi-Hopf algebra and \( t \) a non-zero left integral in \( H \). Theorem [2,5] implies that \( H = H^* \to t \) so the map

\[
\overline{\theta} : H^* \to H, \quad \overline{\theta}(h^*) = h^* \to t = \sum h^*(q'^2t_2p^2)q'^1t_1p^1, \quad \forall h^* \in H^* \tag{2.10}
\]

is bijective. Moreover, \( \overline{\theta} \) is a left \( H \)-linear, where the left \( H \)-action on \( H^* \) is given by the formula

\[
h \cdot h^* = h^* \leftarrow S^{-1}(h)
\]

for \( h \in H \) and \( h^* \in H^* \). If \( H \) is a classical Hopf algebra, then \( \overline{\theta} \) is also left \( H^* \)-linear where the \( H^* \)-actions on \( H^* \) and \( H \) are given by convolution and \( h^* \to h = \sum h^*(h_2)h_1 \) respectively. This means that \( H \) is a left cyclic \( H^* \)-module generated by a left non-zero integral.

## 3 Cointegrals on quasi-Hopf algebras

In the first part of this Section we study the cointegrals on a finite dimensional quasi-Hopf algebra (so the antipode of \( H \) is bijective).

**Definition 3.1** [13] Let \( H \) be a quasi-Hopf algebra, \( M \) an \( H \)-bimodule and \( \rho : M \to M \otimes H \) an \( H \)-bimodule map. Then \((M, \rho)\) is called a right quasi-Hopf \( H \)-bimodule if the following relations hold:

\[
(id_M \otimes \varepsilon) \circ \rho = id_M, \tag{3.1}
\]

\[
\Phi \cdot (\rho \otimes id_M)(\rho(m)) = (id_M \otimes \Delta)(\rho(m)) \cdot \Phi, \quad \forall m \in M. \tag{3.2}
\]

A morphism between two right quasi-Hopf \( H \)-bimodules is an \( H \)-bimodule map \( f : M \to M' \) satisfying \( \rho' \circ f = (f \otimes id) \circ \rho \). \( _H M^H_M \) is the category of right quasi-Hopf \( H \)-bimodules and morphisms of right quasi-Hopf \( H \)-bimodules.

We will use the Sweedler type notation

\[
\rho(m) = \sum m_{(0)} \otimes m_{(1)}, \quad (\rho \otimes id_M)(\rho(m)) = m_{(0,0)} \otimes m_{(0,1)} \otimes m_{(1)}, \quad \text{etc.}
\]

Let \( H \) be a quasi-Hopf algebra and \( M \) a right quasi-Hopf \( H \)-bimodule. We define \( E : M \to M \), by

\[
E(m) = \sum X^1 \cdot m_{(0)} \cdot BS(X^2m_{(1)})\alpha X^3, \tag{3.3}
\]

for all \( m \in M \).

\[
M^{coH} = \{ n \in M \mid E(n) = n \}
\]
is called the space of coinvariants of $M$. We also have (cf. [13, Corollary 3.9])

$$M^{coH} = \{ n \in M \mid \rho(n) = \sum E(x^1 \cdot n) \cdot x^2 \otimes x^3 \}. \quad (3.4)$$

We have the following structure Theorem for right quasi-Hopf $H$-bimodules (see [13, Theorem 3.8]). The map

$$\nu : M^{coH} \otimes H \to M, \nu(n \otimes h) = n \cdot h, \forall n \in M^{coH}, h \in H \quad (3.5)$$

is an isomorphism of right quasi-Hopf $H$-bimodules. Here $M^{coH} \otimes H$ is a right quasi-Hopf $H$-bimodule via the structures $a \cdot (n \otimes h) \cdot b = \sum E(a_1 \cdot n) \otimes a_2 h b$ and $\rho(n \otimes h) = \sum E(x^1 \cdot n) \otimes x^2 h_1 \otimes x^3 h_2$, $\forall n \in N, a, h, b \in H$. The inverse of $\nu$ is given by

$$\nu^{-1}(m) = \sum E(m(0)) \otimes m(1), \forall m \in M. \quad (3.6)$$

Now, let $H$ be a finite dimensional quasi-Hopf algebra; recall that the antipode is then automatically bijective. Let $\{ e_i \}_{i=1}^n$ be a basis in $H$ with dual basis $\{ e^i \}_{i=1}^n$ in $H^*$ and consider

$$U = \sum g^1 S(q^2) \otimes g^2 S(q^1), \quad V = \sum S^{-1}(f^1 p^2) \otimes S^{-1}(f^1 p^1), \quad (3.7)$$

where $f = \sum f^1 \otimes f^2$ is the element defined by (3.15), $f^{-1} = \sum g^1 \otimes g^2$, and $q_R = \sum q^1 \otimes q^2$ and $p_R = \sum p^1 \otimes p^2$ are defined as in (3.19). Following [13], $H^*$ is right quasi-Hopf $H$-bimodule. The structure is the following

$$h \cdot h^* \cdot h' = S(h' \cdot h) \to h^* \leftarrow S^{-1}(h), \forall h, h^*, h' \in H^*, \quad (3.8)$$

$$\rho(h^*) = \sum_{i=1}^n e^i \star h^* \otimes e_i, \forall h^* \in H^*, \quad (3.9)$$

where the (non-associative) multiplication $\star : H^* \otimes H^* \to H^*$ is given by

$$\langle h^* \star g^*, h \rangle = \sum h^* \langle V^1 h_1 U_1^1 \rangle g^* \langle V^2 h_2 U_2^2 \rangle, \forall h^*, g^* \in H^*, h \in H. \quad (3.10)$$

The coinvariants $\lambda \in H^*^{coH}$ are called left cointegrals on $H$ and the space of left cointegrals is denoted by $L$. Thus $\dim_k^H L = 1$ and the projection $E : H^* \to L$ is given by

$$\langle E(h^*), h \rangle = \sum_{i=1}^n \langle e^i \otimes h^*, \Delta(S^{-1}(q^1)h S^2(q^2 e_i) S(\beta)) \rangle, \quad (3.11)$$

for all $h^* \in H^*$ and $h \in H$. Here $\Delta(h) = \sum V^1 h_1 U_1 \otimes V^2 h_2 U_2$, for any $h \in H$. The transpose $E^T : H \to H$ is given by

$$E^T(h) = \sum_{i=1}^n \langle e^i \otimes id, \Delta(S^{-1}(q^1)h S^2(q^2 e_i) S(\beta)) \rangle, \forall h \in H \quad (3.12)$$

and provides a projection onto the space of right integrals in $H$. Moreover, the dual pairing $L \otimes \int^H_r \to k$, $\lambda \otimes r \to \langle \lambda, r \rangle$ is nondegenerate, [13, Lemma 4.4].

When $H$ is an ordinary Hopf algebra the left cointegrals on $H$ are precisely the left integrals in $H^*$ (i.e., an element $\lambda \in H^*$ such that $\sum \lambda(h_1) h_2 = \lambda(h) 1, \forall h \in H$). For quasi-Hopf algebras $H$ we will give some characterizations for left cointegrals. First, we need another formula for the projection (3.11), giving the connection between the projection $P$ onto the space of left integrals defined by (2.1) and the projection $E^T$, defined by (3.12). This provides an answer to a question raised in [13].
Lemma 3.2 Let $H$ be a finite dimensional quasi-Hopf algebra and $E$ the map defined by (3.11). Then, for all $h^* \in H^*$ and $h \in H$, we have:

$$\langle E(h^*), h \rangle = \langle h^*, S^{-1}(P(S(h))) \rangle.$$ (3.13)

In particular, if $E^T$ is the transpose map (3.14) and $P : H \to \mathbb{1}_H$ is the projection (2.7) then $E^T(h) = S^{-1}(P(S(h)))$, for all $h \in H$.

Proof. Take $f = \sum f^1 \otimes f^2 = \sum F^1 \otimes F^2$ and $f^{-1} = \sum g^1 \otimes g^2 = \sum G^1 \otimes G^2$ as in (1.15) and (1.16). It is easy to see that

$$\sum g^1 S(g^2 \alpha) = \beta, \quad \sum S(\beta f^1) f^2 = \alpha, \quad \sum f^1 \beta S(f^2) = S(\alpha)$$ (3.14)

and we compute, for $h^* \in H^*$ and $h \in H$:

$$\langle E(h^*), h \rangle = \sum_{i=1}^n \langle e^i \otimes h^*, S^{-1}(q^1) h S^2(q^2 e_i) S(\beta) \rangle$$

(3.7 [1.11])

$$= \sum_{j=1}^n \langle e^j, h S^2(q^2 S^{-1}(f^2 q^2 e_j) \alpha) S(\beta) \rangle \langle h^*, S^{-1}(f^1 q^1 p^1) (e_j)_2 U^2 \rangle$$

(3.12) [1.19]

$$\langle h^*, S^{-1}(f^1)(e_j)_2 g^2 S(X^1) \rangle$$

(1.9 [1.18])

$$= \sum_{j=1}^n \langle e^j, h S^2(S^{-1}(f^2) \alpha)(e_j)_1 F^2 X^2 g^2 S^{-1}(\beta) \rangle \langle h^*, S^{-1}(f^1)(e_j)_2 X^3 \rangle$$

(3.14) [1.5]

$$\langle h^*, S^{-1}(S(e_1))_2 S^{-1}(f^2) X^3 S^{-1}(\alpha) X^1 \beta \rangle$$

(3.14) [1.11]

$$= \sum_{j=1}^n \langle e^j, h S^2(S^{-1}(S(e_1))_2 S^{-1}(f^2) X^3 S^{-1}(\alpha) X^1 \beta) \rangle$$

(1.9 [1.18])

$$= \sum_{j=1}^n \langle e^j, h S(S(e_1)_2) S(\beta F^1 f^2 X^2 g^2 \alpha) \rangle \langle h^*, S^{-1}(f^1 X^1 g^1) \rangle$$

(3.14) [1.5]

$$= \sum_{j=1}^n \langle e^j, \beta S((e_j)_2) S(\alpha X^3 g^2 \alpha) \rangle \langle h^*, S^{-1}(X^1 (e_j)_1) \rangle$$

(3.14) [2.1]

$$= \langle h^*, S^{-1}(P(S(h))) \rangle.$$}

The last assertion follows easily by (3.13) and (3.12). □

Lemma 3.3 Let $H$ be a finite dimensional quasi-Hopf algebra and $E : H^* \to \mathbb{L}$ the projection (3.11). Then

$$E(h^* \leftarrow S^{-1}(h)) = \mu(h) E(h^*), \quad \forall h^* \in H^* \text{ and } h \in H,$$ (3.15)

$$\lambda(S^{-1}(h) h') = \sum \mu(h_1) \lambda(h' S(h_2)), \quad \forall h, h' \in H,$$ (3.16)

where $\mu$ is the distinguished grouplike element of $H^*$. 

13
Proof. The relations (3.15) follow easily from (3.13) and the fact that \( P(h) \in \mathcal{J}^H \), \( \forall h \in H \). To prove (3.16), let \( \{ e_i \}_{i=1}^n \) be a basis in \( H \) with dual basis \( \{ e_i^* \}_{i=1}^n \) in \( H^* \) and \( q_R \) the element defined by (1.19).

For all \( h, h' \in H \) and \( \lambda \in \mathcal{L} \) we have:

\[
\lambda(S^{-1}(h)h') = \langle E(\lambda), S^{-1}(h)h' \rangle
\]

(3.13) [2.1] = \[
\sum_{i=1}^{n} \langle e_i^*, \beta S^2(q^2(e_i)_2)S(h'h) \rangle \langle \lambda, S^{-1}(q^1(e_i)_1) \rangle
\]

= \[
\sum_{j=1}^{n} \langle e_j^*, \beta S^2(q^2(e_j)_2)S(h'h) \rangle \langle \lambda, S^{-1}(q^1(e_j)_1h_1) \rangle
\]

2.1 [3.13] = \[
\sum (E(\lambda \leftarrow S^{-1}(h_1)), h'S(h_2))
\]

(3.15) = \[
\sum \mu(h_1) \lambda(h'S(h_2)).
\]

\( \square \)

**Proposition 3.4** Let \( H \) be a finite dimensional quasi-Hopf algebra and \( \mu \) the distinguished grouplike element of \( H^* \). For \( \lambda \in H^* \), the following statements are equivalent:

(a) \( \lambda \) is a left cointegral on \( H \);

(b) for all \( h \in H \), we have

\[
\sum \lambda(S^{-1}(f^1)h_2S^{-1}(q^1g^1))S^{-1}(f^2)h_1S^{-1}(q^2g^2) = \sum \mu(q^1x^1)(\lambda, hS(q^1x^2))q^2x^3S^{-1}(f^2)g^1; \tag{3.17}
\]

(c) for all \( h \in H \), we have

\[
\sum \lambda(S^{-1}(f^1)h_2U^2)S^{-1}(f^2)h_1U^1 = \sum \mu(q^1x^1)(\lambda, hS(q^1x^2))q^2x^3.
\]

Here \( f = \sum f^1 \otimes f^2 \), \( q_R = \sum q^1 \otimes q^2 \) and \( U = \sum U^1 \otimes U^2 \) are defined respectively by (1.15), (1.14) and (1.7), and \( f^{-1} = \sum g^1 \otimes g^2 \).

**Proof.** (a) \( \implies \) (b). Suppose that \( \lambda \) is a left cointegral. As before, we write \( f = \sum f^1 \otimes f^2 = \sum F^1 \otimes F^2 = \sum \mathcal{F}^1 \otimes \mathcal{F}^2 \), \( f^{-1} = \sum g^1 \otimes g^2 = \sum G^1 \otimes G^2 = \sum \mathcal{G}^1 \otimes \mathcal{G}^2 \), \( q_R = \sum q^1 \otimes q^2 \) and \( p_R = \sum p^1 \otimes p^2 \). Using (3.4), (3.8), (3.9) and (3.15), we find that

\[
\sum \lambda(V^2h_2U^2)V^1h_1U^1 = \sum \mu(x^1) \lambda(hS(x^2))x^3; \tag{3.18}
\]

for all \( h \in H \), and we compute that

\[
\sum \mu(q^1x^1)(\lambda, hS^{-1}(f^1)g^2S(q^1x^2))q^2x^3S^{-1}(f^2)g^1
\]

(3.15) [3.18] = \[
\sum (\lambda, V^2[S^{-1}(q^1)hS^{-1}(f^1)g^2]_2U^2)q^2V^1[S^{-1}(q^1)hS^{-1}(f^1)g^2]_1U^1
\]

\( S^{-1}(f^2)g^1 \)

(3.7) [1.1] = \[
\sum (\lambda, S^{-1}(F^1q^1p^1)h_2S^{-1}(F^1f^1G^1)g^2U^2)q^2S^{-1}(F^2q^2p^2)h_1S^{-1}(F^2f^2G^2)
\]

\( g^2U^1S^{-1}(f^2)g^1 \)

(3.12) [1.1] = \[
\sum (\lambda, S^{-1}(S(h)_1)S^{-1}(F^1f^1)g^2G^2S(X^1))S^{-1}(S(h)_2)S^{-1}(F^2f^2G^2)
\]

\( g^2G^1S(X^2)\alpha S^{-1}(S^1(f^2)g^1S(X^3)) \)
\[
\begin{align*}
(\ref{eq:1.3.18}) & = \sum (\lambda, S^{-1}(S(h_1))S^{-1}(S(X^3)F^1 f_1^1)g^2)S^{-1}(S(h_2))S^{-1}(S(X^2)F^2 f_2^1) \\
& \quad \times g_1^2 G^2 \alpha S^{-1}(S(X^1) f_2^1)g_1^2 G^1 \\
(\ref{eq:3.14.15}) & = \sum (\lambda, S^{-1}(S(h_1))S^{-1}(S(X^3)F^1 f_1^1))S^{-1}(S(h_2)) \\
& \quad \times S^{-1}(S(X^1) f_2^1)S^{-1}(S(X^2)F^2 f_2^1) \\
(\ref{eq:1.3.18}) & = \sum (\lambda, S^{-1}(S(h_1))S^{-1}(f^1 X^1))S^{-1}(S(h_2))S^{-1}(S^{-1}(F^2 f_2^1 X^3)\beta F^1 f_2^1 X^2) \\
(\ref{eq:3.14.15}) & = \sum (\lambda, S^{-1}(X^1 S(h_1)))S^{-1}(S^{-1}(\alpha X^3)X^2 S(h_2)) \\
(\ref{eq:1.13.1}) & = \sum (\lambda, S^{-1}(f^1))h_2 S^{-1}(q^1 g^1))S^{-1}(f^1)h_1 S^{-1}(q^2 g^2). \\
\end{align*}
\]

\((b) \implies (a)\). Assume that \(\lambda \in H^*\) satisfies \((\ref{eq:3.17})\). It follows from \((\ref{eq:1.11})\) that
\[
\sum \lambda(S^{-1}(q^1 h_1))q^2 h_2 = \sum \mu(q^1 x^1)\langle \lambda, S^{-1}(f^1)g^2 S(q_2 x^2)\rangle S^{-1}(f^2)g^1 S(q^2 x^3), \tag{3.19}
\]
for all \(h \in H\) and
\[
\langle \lambda, S^{-1}(P(S(h))) \rangle = \sum \mu(q^1 x^1)\langle \lambda, S^{-1}(f^1)g^2 S(q_2 x^2)\rangle S^{-1}(f^2)g^1 S(q^2 x^3), \tag{3.19}
\]
\[
\langle \lambda, S^{-1}(f^1)h_2 S^{-1}(q^1 g^1)S^{-1}(f^2)h_1 S^{-1}(q^2 g^2) \rangle = \lambda(h),
\]
and it follows from Lemma \((\ref{eq:3.2})\) that \(\lambda \in L\).

\((c) \implies (a)\). Repeating the computations of the first part of the proof of Lemma \((\ref{eq:3.2})\) we find that the projection \(E\) (cf. \((\ref{eq:3.11})\)) is given by
\[
\langle E(h^*), h \rangle = \sum_{i=1}^{n} \langle e_i^1, h S(f^2)S((e_i)_1 U^1)S(\beta) \rangle \langle h^*, S^{-1}(f^1)(e_i)_2 U^2 \rangle, \tag{3.20}
\]
for all \(h^* \in H, h \in H\). Using \((\ref{eq:3.20})\), we can compute that \(E(\lambda) = \lambda, \) so \(\lambda \in L\).

\((a) \implies (c)\). Assume that \(\lambda \in L\). We calculate
\[
\sum \mu(q^1 x^1)\langle \lambda, h S(q_2 x^2)\rangle q^2 x^3 = \sum \langle \lambda, V^2[S^{-1}(q^1)h]_2 U^2 \rangle q^2 V^1[S^{-1}(q^1)h]_1 U^1 \tag{3.16.3.18}
\]
\[
\sum \langle \lambda, S^{-1}(f^1)h_2 U^2 \rangle S^{-1}(f^2)h_1 U^1 \tag{3.17.1.11.1.21}
\]
and the proof is complete. \(\square\)

\textbf{Remark 3.5} Formula \((\ref{eq:3.19})\) is equivalent to \((\ref{eq:3.17})\), and can be viewed as another characterization of left cointegrals. In the case of a Hopf algebra, \((\ref{eq:3.19})\) takes the form
\[
\sum \lambda(S^{-1}(h_1))h_2 = \lambda(S^{-1}(h))1
\]
which is the well-known statement that \(\lambda\) is a left integral if and only if \(\lambda \circ S^{-1}\) is a right integral.

Observe that our Definition of cointegral only makes sense in the case where \(H\) is finite dimensional: indeed, we need a dual basis of \(H\) in order to make \(H^*\) into a right quasi-Hopf bimodule (see \((\ref{eq:3.9})\)). Also the equivalent characterizations from Proposition \((\ref{eq:3.4})\) make no sense in the infinite dimensional case, as they involve the distinguished element, which can only be defined in the finite dimensional case. Nevertheless, the cointegral has a lot of applications in the finite dimensional case (see \((\ref{eq:1.3})\)).
Following [6, Lemma 4.1], we now give an alternative definition for the space of coinvariants of a right quasi-Hopf $H$-bimodule $M$:

$$M^{coH} = \{ n \in M \mid \rho(n) = \sum x^1 \cdot n \cdot S(x_3^3 X^3) f^1 \otimes x^2 X^1 \beta S(x_1^3 X^2) f^2 \}.$$  (3.21)

Using this definition, we will prove a second Structure Theorem for right quasi-Hopf bimodules. For $M \in hM_H$, we define

$$\mathcal{E} : M \rightarrow M, \quad \mathcal{E}(m) := \sum m_{(0)} \cdot \beta S(m_{(1)}), \quad \forall m \in M.$$  (3.22)

It follows that

$$\mathcal{E}(m) = \sum E(p^1 \cdot m) \cdot p^2, \quad E(m) = \sum X^1 \cdot \mathcal{E}(m) \cdot S(X^2) \alpha X^3, \quad \forall m \in M.$$  (3.23)

By [13, Proposition 3.4], we have

$$E(m \cdot h) = \varepsilon(h)E(m), \quad E(h \cdot E(m)) = E(h \cdot m), \quad h \cdot E(m) = \sum E(h_1 \cdot m) \cdot h_2$$  (3.24)

for all $m \in M$ and $h \in H$, and therefore the maps

$$\mathcal{E} : M^{coH} \rightarrow M^{coH} \quad \text{and} \quad E : M^{coH} \rightarrow M^{coH}$$  (3.25)

are each others inverses. In the case of a classical Hopf algebra, the maps $E$ and $\mathcal{E}$ are equal to the identity on $M^{coH} = M^{coH}$. Moreover, in this case $M^{coH}$ is invariant under the left adjoint $H$-action $h \triangleright m := \sum h_1 \cdot m \cdot S(h_2)$, in the sense that $E(h \triangleright m) = h \triangleright E(m)$, $h \in H$, $m \in M$. In the quasi-Hopf case the projection $E$ generalizes this property. More precisely, if we define $h \rhd m = E(h \cdot m)$, then by [13, Proposition 3.4], we have that $h \cdot E(m) = \sum [h_1 \rhd E(m)] \cdot h_2$. Now, as in the Hopf algebra case, we will prove that $M^{coH}$ is invariant under the left adjoint $H$-action.

**Lemma 3.6** Let $H$ be a quasi-Hopf algebra, $M$ a right quasi-Hopf $H$-bimodule

(a) $\text{Im}(\mathcal{E}) \subseteq M^{coH}$. If $n \in M$ then $n \in M^{coH} \iff \mathcal{E}(n) = n$.

(b) $M^{coH}$ is a left $H$-submodule of $M$, where $M$ is considered a left $H$-module via the left adjoint action, that is $h \triangleright m := \sum h_1 \cdot m \cdot S(h_2)$, for all $h \in H$ and $m \in M$.

**Proof.** (a) Let $m \in M$ and $\delta = \sum \delta^1 \otimes \delta^2$ be given by (1.14). Then

$$\rho(\mathcal{E}(m)) = \sum m_{(0,0)} \cdot \beta_1 S(m_{(1)})_1 \otimes m_{(0,1)} \beta_2 S(m_{(1)})_2$$  (1.17)

$$= \sum m_{(0,0)} \cdot \delta^1 S(m_{(1)})_2 \cdot f^1 \otimes m_{(0,1)} \delta^2 S(m_{(1)})_1 \cdot f^2$$  (1.11)

$$= \sum m_{(0,0)} \cdot x^1 \beta S(m_{(1)} X^3) f^1 \otimes m_{(0,1)} x^2 X^1 \beta S(m_{(1)} X^3) f^2$$  (3.21)

$$= \sum x^1 \cdot m_{(0)} \cdot \beta S(x_3^3 X^3) f^1 \otimes x^2 X^1 \beta S(x_3^3 X^2) f^2$$  (1.14)

$$= \sum x^1 \cdot \mathcal{E}(m) \cdot S(x_3^3 X^3) f^1 \otimes x^2 X^1 \beta S(x_3^3 X^2) f^2.$$  (3.15)

Therefore $\text{Im}(\mathcal{E}) \subseteq M^{coH}$, implying immediately one implication of the second part. Conversely, if $n \in M^{coH}$ then

$$\mathcal{E}(n) = \sum n_{(0)} \cdot \beta S(n_{(1)}),$$  (3.23)

$$= \sum x^1 \cdot n \cdot S(x^2 X^1 \beta S(x_3^3 X^2) \alpha x_3^3 X^3)$$  (3.14)

$$= n.$$  (3.16)
(b) If $M$ is an $H$-bimodule then is not hard to see that $M$ is a left $H$-module via the $H$-action $h \triangleright m = \sum h_1 \cdot m \cdot S(h_2)$, $h \in H$, $m \in M$. Using (3.23), (3.24) and (1.20) we have that $E(h \triangleright m) = h \triangleright E(m)$ for all $h \in H$, $m \in M$. By part (a), we see that $\overset{\circ}{M}$ is a left $H$-module under the left adjoint action.

Let $H$ be a quasi-Hopf algebra and $M$ a right quasi-Hopf $H$-bimodule. We already have seen that the map $E : M^{\text{coH}} \to \overset{\circ}{M}$ is an isomorphism. It is also $H$-linear since

$$E(h \cdot n) = E(h \cdot E(n))$$

for all $h \in H$ and $n \in M^{\text{coH}}$.

$\overset{\circ}{M}$ is a left $H$-module, so, by [13, Lemma 3.2], $\overset{\circ}{M} \otimes H$ becomes a right quasi-Hopf $H$-bimodule with the following structure:

$$a \cdot (n \otimes h) \cdot b = \sum a_1 \triangleright n \otimes a_2 h h_1 \triangleright n \otimes x^2 h_1 \otimes x^3 h_2$$

(3.26)

for all $a, b, h \in H$ and $n \in \overset{\circ}{M}$. We can now state the second Structure Theorem for right quasi-Hopf bimodules.

**Theorem 3.7** Let $H$ be a quasi-Hopf algebra and $M$ a right quasi-Hopf $H$-bimodule. Consider $\overset{\circ}{M} \otimes H$ as a right quasi-Hopf $H$-bimodule as in (3.24). The map

$$\nabla : \overset{\circ}{M} \otimes H \to M, \ \nabla(n \otimes h) = \sum X^{1} \cdot n \cdot S(X^{2}) \alpha X^{3} h$$

(3.27)

is an isomorphism of quasi-Hopf $H$-bimodules. The inverse of $\nabla$ is given by the formula

$$\nabla^{-1}(m) = \sum E(m_{(0)}) \otimes m_{(1)}.$$  

(3.28)

**Proof.** We have seen that $\overset{\circ}{M} \cong M^{\text{coH}}$ are isomorphic as left $H$-modules, and therefore $\overset{\circ}{M} \otimes H \cong M^{\text{coH}} \otimes H$ as quasi-Hopf $H$-bimodules (in both cases, the structure is determined by [13, Lemma 3.2]). From the Hausser-Nill Structure Theorem ([13, Theorem 3.8]), it follows that $M \cong M^{\text{coH}} \otimes H$ as quasi-Hopf $H$-bimodules. Thus we find that $\overset{\circ}{M} \otimes H \cong M$ as quasi-Hopf $H$-bimodules, and it is straightforward to verify that the connecting isomorphism is exactly $\nabla$.

**Remark 3.8** Theorem 3.7 can be proved also in a direct way, without using the Hausser-Nill Structure Theorem. This proof is straightforward, but long and technical. However, it has the advantage that it is independent of the bijectivity of the antipode, which makes it more general in the infinite dimensional case. At first sight, the Haussler-Nill definition of coinvariants makes use of the bijectivity of the antipode; however, a careful inspection of their definition and their proof of the Structure Theorem shows that we do not really need the bijectivity.

The antipode of a finite dimensional quasi-Hopf algebra is bijective, so its dual $H^*$ is a right quasi-Hopf $H$-bimodule with structures defined in (3.3), (3.9). The coinvariants $\overline{\lambda} \in H^*^{\text{coH}}$ are called left alternative cointegrals on $H$, and the space of left alternative cointegrals is denoted by $\overline{L} = H^*^{\text{coH}}$. From Theorem 3.7, we obtain immediately the following result:

**Theorem 3.9** Let $H$ be a finite dimensional quasi-Hopf algebra. Then $\text{dim}_k \overline{L} = 1$.  

17
Applying (4.3) and (4.5), we find that \( \lambda \in H^* \) is an alternative left cointegral if and only if
\[
\sum \lambda(V^2 h_2 U^2) V^1 h_1 U^1 = \sum \lambda(S^{-1}(X_1^1 p^1) h(S(X_3^1) f^1)) X_1^2 p^2 S(X_3^2) f^2
\]
for all \( h \in H \). (3.29) can be used to extend the definition of left alternative cointegral to infinite dimensional quasi-Hopf algebras.

### 4 Integrals for dual quasi-Hopf algebras

Sullivan’s Theorem [23] asserts that the space of left integrals on a Hopf algebra has dimension at most one. Various new proofs of this result have been given in recent years, see [23], [3], [3] and [21]. The aim of this Section is to give a proof of the uniqueness of integrals on a dual quasi-Hopf algebra. Our approach is based on the methods developed in [3]. Throughout, \( A \) will be a dual quasi-bialgebra or a dual quasi-Hopf algebra. Following [17], a dual quasi-bialgebra \( A \) is a coassociative coalgebra \( A \) with comultiplication \( \Delta \) and counit \( \varepsilon \) together with coalgebra morphisms \( M : A \otimes A \to A \) (the multiplication; we write \( M(a \otimes b) = ab \)) and \( u : k \to A \) (the unit; we write \( u(1) = 1 \)), and an invertible element \( \varphi \in (A \otimes A \otimes A)^* \) (the reassociator), such that for all \( a, b, c, d \in A \) the following relations hold:

\[
\sum a_1(b_1 c_1) \varphi(a_2, b_2, c_2) = \sum \varphi(a_1, b_1, c_1)(a_2 b_2) c_2,
\]

\[
1a = a 1 = a,
\]

\[
\sum \varphi(a_1, b_1, c_1) \varphi(a_2 b_2, c_2, d_2) = \sum \varphi(b_1, c_1, d_1) \varphi(a_1, b_2 c_2, d_2) \varphi(a_2, b_3, c_3),
\]

\[
\varphi(a, 1, b) = \varepsilon(a) \varepsilon(b).
\]

\( A \) is called a dual quasi-Hopf algebra if, moreover, there exist an antimorphism \( S \) of the coalgebra \( A \) and elements \( \alpha, \beta \in H^* \) such that, for all \( a \in A \):

\[
\sum S(a_1) \alpha(a_2) a_3 = \alpha(a) 1, \quad \sum a_1 \beta(a_2) S(a_3) = \beta(a) 1,
\]

\[
\sum \varphi(a_1) \beta(a_2) S(a_3), \alpha(a_4) a_5) = \sum \varphi^{-1}(S(a_1), \alpha(a_2) a_3, \beta(a_4) S(a_5)) = \varepsilon(a).
\]

It follows from the axioms that \( \alpha(1) \beta(1) = 1 \), so we can assume that \( \alpha(1) = \beta(1) = 1 \) and, \( S(1) = 1 \). Moreover (4.3) and (4.4) imply

\[
\varphi(1, a, b) = \varphi(a, b, 1) = \varepsilon(a) \varepsilon(b), \quad \forall a, b \in A.
\]

If \( A = (A, M, u, \varphi, S, \alpha, \beta) \) is a dual quasi-Hopf algebra, then \( A^{op, cop} \) is also a dual quasi-Hopf algebra. The structure maps are

\[
\varphi_{op, cop}(a, b, c) = \varphi(c, b, a), \quad S_{op, cop} = S, \quad \alpha_{op, cop} = \beta \quad \text{and} \quad \beta_{op, cop} = \alpha.
\]

If \( A \) is a dual quasi-bialgebra, then \( A^* \) is an algebra, with multiplication given by convolution, and unit \( \varepsilon \).

**Definition 4.1** A map \( T \in A^* \) is called a left integral on the dual quasi-bialgebra \( A \) if \( a^* T = a^* (1) T \) for any \( a^* \in A^* \). Left integrals on \( A^{op, cop} \) are called right integrals on \( A \).
The set of left (right) integrals on $A$ is denoted by $\int_l (\int_r)$. We keep the same notation as in Section 3 but we will specify every time which kind of integral we are using. It is clear that $T \in A^*$ is a left integral if and only if $\sum T(a_2)a_1 = T(a)1$ for all $a \in A$. $\int_l$ is a subspace of $A^*$. Moreover, as in the Hopf algebra case, $\int_l$ is a two-sided ideal in the algebra $A^*$.

Let $A^{rat}$ be the left rational part of $A^*$. $A^{rat}$ is the sum of rational left ideals of the algebra $A^*$, see [24, Ch. II]. Note that $A^{rat} \subseteq A^*$ and

$$a^* \in A^{rat} \iff \exists (a_i^*)_{i=1}^n \subseteq A^* \text{ and } (a_i)_{i=1}^n \subseteq A \text{ such that } b^*a^* = \sum_{i=1}^n b^*(a_i)a_i^*, \ \forall b^* \in A^*.$$  \hspace{1cm} (4.8)

It follows that $\int_l \subseteq A^{rat}$. In particular, if $A^{rat} = 0$, then $\int_l = 0$.

Later in this Section we will show that the left and right rational parts of $A^*$ are equal, justifying our notation. As in the Hopf algebra case, we first describe the connection between $A^{rat}$ and $\int_l$. It is well-known that $A^{rat}$ is a rational left $A^*$-module, and this induces a right $A$-comodule structure on $A^{rat}$ defined by

$$\rho : A^{rat} \to A^{rat} \otimes A, \rho(a^*) = \sum a^*_0 \otimes a^*_1 \iff b^*a^* = \sum b^*(a^*_1)a^*_0,$$  \hspace{1cm} (4.9)

for all $b^* \in A^*$. This can be rewritten as follows

$$\rho(a^*) = \sum a^*_0 \otimes a^*_1 \iff \sum a^*(a_2)a_1 = \sum a^*_0(a)a_1^*, \ \forall a \in A.$$  \hspace{1cm} (4.10)

Now, define the map $\sigma : A \otimes A \to A^*$ by

$$\sigma(a \otimes b)(c) = \varphi(c, a, b), \ \forall a, b, c \in A.$$  \hspace{1cm} (4.11)

$\sigma$ is convolution invertible, the inverse $\sigma^{-1}$ is given by $\sigma^{-1}(a \otimes b)(c) = \varphi^{-1}(c, a, b)$, for all $a, b, c \in A$.

We introduce the following notation, for $a^* \in A^*$ and $a \in A$:

$$a^* \leftarrow a = S(a) \rightarrow a^* \in A^*.$$  

For all $a^* \in A^{rat}$, we define $P^*(a^*)$ by

$$P^*(a^*) = \sum \beta(a^*_1)\alpha(S(a^*_3))\sigma(S^2(a^*_4) \otimes S(a^*_2))(a^*_0) \leftarrow S(a^*_5)).$$  \hspace{1cm} (4.12)

We now claim that $P^*(a^*) \in \int_l$, for all $a^* \in A^{rat}$. Indeed, for all $b^* \in A^*$, we calculate

$$\langle b^* (1)P^*(a^*), a \rangle$$  \hspace{1cm} (4.12 \ [4.5]) = \sum \langle b^*, a^*_1 \beta(a^*_2)S(a^*_3)\alpha(S(a^*_5))\sigma(a_1, S^2(a^*_6), S(a^*_4)) \rangle$$

$$\langle a^*_0, a_2S^2(a^*_7) \rangle$$  \hspace{1cm} (4.10 \ [4.1]) = \sum \beta(a^*_1) \langle b^*, a_1[S^2(a^*_5)\alpha(S(a^*_4))S(a^*_3)]\varphi(a_2, S^2(a^*_6), S(a^*_2)) \rangle$$

$$\langle a^*_0, a_3S^2(a^*_7) \rangle$$  \hspace{1cm} (4.5 \ [4.12]) = \sum b^*(a^*_1)\langle P^*(a^*), a_2 \rangle = \langle b^* P^*(a^*), a \rangle.$$

**Proposition 4.2** Let $A$ be a dual quasi-Hopf algebra and $\sigma : A \otimes A \to A^*$ the map defined in (4.11). Then $\theta^* : \int_l \otimes A \to A^{rat}$, given by

$$\theta^*(T \otimes a) = \sum \sigma(S(a_5), \alpha(a_6)\alpha_7)(T \leftarrow a_4)\sigma^{-1}(S(a_3) \otimes \beta(a_2)S^2(a_1)),$$  \hspace{1cm} (4.13)

is an isomorphism of right $A$-comodules.
Proof. In the situation where $A$ is finite dimensional, the proof follows from Theorem 2.2 by duality. This is why we restrict to proving that $\theta^*$ is well-defined and has an inverse, leaving other details to the reader. For $a^* \in A^*$, $T \in \mathcal{I}$, and $a \in A$, we compute that

$$\langle a^* \theta^*(T \otimes a), b \rangle = \sum a^*(b_1)\phi(b_2, S(a_5), \alpha(a_6)a_7)T(b_3S(a_4))\varphi^{-1}(b_4, S(a_3), \beta(S(a_2))S^2(a_1))$$

(4.5)

$$= \sum (a^*, b_1(S(a_6)\alpha(a_7)a_8))\phi(b_2, S(a_5), a_9)T(b_3S(a_4))\varphi^{-1}(b_4, S(a_3), \beta(S(a_2))S^2(a_1))$$

(4.1)

$$= \sum ((a_8 \rightarrow a^*)T, b_2S(a_4))\phi(b_1, S(a_5), \alpha(a_6)a_7)\varphi^{-1}(b_3, S(a_3), \beta(S(a_2))S^2(a_1))$$

(4.1)

$$= \sum a^*(a_2)|\theta^*(T \otimes a_1), b|$$

hence

$$a^* \theta^*(T \otimes a) = \sum a^*(a_2)\theta^*(T \otimes a_1).$$

(4.14)

From (4.8) it follows that $\theta^*(T \otimes a) \in A^{rat}$, as needed.

If $\mathcal{I} \otimes A$ is a right $A$-comodule with structure induced by the comultiplication on $A$, and it follows then from (4.5) that $\theta^*$ is right $A$-colinear.

We claim that the inverse of $\theta^*$ is given by

$$\theta^{*-1}: A^{rat} \rightarrow \mathcal{I} \otimes A, \theta^{*-1}(a^*) = \sum P^*(a^*_0) \otimes a^*_1,$$

(4.15)

where $\varrho(a^*) = \sum a^*_0 \otimes a^*_1 \in A^{rat} \otimes A$ is defined as in (4.9). It is clear that $\theta^{*-1}$ is well defined. To show that $\theta^*$ and $\theta^{*-1}$ are each others inverses, we need the following equalities, for any $T \in \mathcal{I}$ and $a, b \in A$:

$$\sum \varphi(a_2, S(b_2), \alpha(b_3)b_4)T(a_5S(b_1))a_1 = \sum \varphi(a_1, S(b_2), S(b_3)b_4)T(a_2S(b_1))b_5,$$

(4.16)

$$T(aS(b)) = \sum \varphi(\beta(a_1)T, b_2)\alpha(b_3)b_4T(a_5S(b_1))$$

(4.17)

$$= \sum \varphi(\beta(a_1)a_2, S(b_2), \alpha(b_3)b_4)T(a_5S(b_1)).$$

Note that these formulas are the formal duals of (2.2) and (2.3). \qed

Corollary 4.3 Let $A$ be a dual quasi-Hopf algebra. Then $A^{rat} = 0$ if and only if $\mathcal{I} = 0$.

Corollary 4.4 Assume that a dual quasi-Hopf algebra $A$ has a non-zero left integral. Then the antipode $S$ is injective. If $A$ is finite dimensional, then the left integral space has dimension 1, and the antipode $S$ is bijective.

Proof. Let $T$ be a non-zero left integral, and assume that $S(a) = 0$. Let $\overline{S}$ be the algebra antimorphism dual to $S$. If $\theta^*$ is the map defined by (4.13) then for all $a^* \in A^*$ and $b \in A$ we have:

$$\langle \theta^*(T \otimes \overline{S}(a^*) \rightarrow a), b \rangle = \sum \overline{S}(a_3)\theta^*(T \otimes a_1), b \rangle$$

(4.17)

$$= \sum \overline{S}(a_3)\theta^*(T(b_2S(a_4)))\varphi^{-1}(b_3, S(a_3), \beta(S(a_2))S^2(a_1))$$

(4.17)

$$= \sum a^*(S(a_3))T(b_1S(a_4))\varphi^{-1}(b_2, S(a_3), \beta(S(a_2))S^2(a_1)) = 0.$$
Since \( \theta^* \) is bijective and \( T \neq 0 \) it is follows that \( \beta S(a^*) \mapsto a = 0 \), for any \( a^* \in A^* \). Thus \( \sum \beta(a_2) a_1 \otimes S(a_3) = 0 \) and therefore
\[
\sum \beta(a_5) a_1 \otimes a_2 \otimes a_3 \otimes a_4 \otimes S(a_6) = 0.
\]
By (4.6) we obtain that \( a = \sum \varphi^{-1}(S(a_2), a(a_3) a_4, \beta(a_5) S(a_6)) a_1 = 0 \), and \( S \) is injective.

If \( A \) is finite dimensional then \( A^{rat} = A^* \). We obtain that \( \theta^* : \int_I A \to A^* \) is an isomorphism of right \( A \)-comodules. The final assertion is then obvious. \( \square \)

Let \( C \) be a coalgebra and \( C^* \) the dual algebra. Then \( C \) is a left (right) \( C^* \)-module under the left (right) action \( \mapsto (\mapsto) \) of \( C^* \) on \( C \) given by \( c^* \mapsto c = \sum c^*(c_2)c_1 \) (\( c \mapsto c^* = \sum c^*(c_1)c_2 \)), for all \( c^* \in C^* \) and \( c \in C \).

Recall that \( C \) is called a left (right) quasi-co-Frobenius coalgebra (shortly QcF coalgebra) if there exists an injective morphism of left (right) \( C^* \)-modules from \( C \) to a free left (right) \( C^* \)-module. The coalgebra \( C \) is called left (right) co-Frobenius if there exists a monomorphism of (left) right \( C^* \)-modules from \( C \) to \( C^* \) or, equivalently, if there exists a bilinear form \( b : C \otimes C \to k \) which is left (right) non-degenerated and \( C^* \)-balanced, i.e. if \( b(c, x) = 0 \) for any \( c \in C \) (resp. \( b(x, c) = 0 \) for any \( c \in C \)) then \( x = 0 \) and \( b(x \mapsto c^*, y) = b(x, c^* \mapsto y) \) for any \( x, y \in C \), \( c^* \in C^* \).

Finally, \( C^* \) is a left (right) \( C^* \)-module, so we can consider the left (right) rational part of \( C^* \). We will denote this \( C^* \)-submodule of \( C^* \) by \( C^{rat}_l \) (resp. \( C^{rat}_r \)). \( C \) is called a left (right) semiperfect coalgebra if the category \( C^* \mathcal{M} (\mathcal{M}^C) \) of left (right) \( C \)-comodules has enough projectives or, equivalently, \( C^{rat}_l (C^{rat}_r) \) is a dense subset of \( C^* \) (in the finite topology, see [1], [7] for the Definition). Following [3], if \( C \) is a left and right semiperfect coalgebra then \( C^{rat}_l = C^{rat}_r := C^{rat} \), \( C^{rat} \) is dense in \( C^* \) and \( C \) is projective generator in the categories \( C^* \mathcal{M} \) and \( \mathcal{M}^C \).

It is known that a left (right) co-Frobenius coalgebra is a left (right) QcF coalgebra and a left (right) QcF coalgebra is a left (right) semiperfect coalgebra, but the converse implications are not true. There are examples showing that none of the three concepts is left-right symmetric. However, if \( H \) is a Hopf algebra all these concepts are equivalent to \( H \) having non-zero left (or right) integrals. We prove now that a similar result holds for dual quasi-Hopf algebras. Except for the implication \((i) \Rightarrow (ii)\), the proof is identical to the proof of [7, Theorem 5.3.2], so we omit it here.

**Theorem 4.5** Let \( A \) be a dual quasi-Hopf algebra. Then the following assertions are equivalent:

(i) \( A \) has a non-zero integral.
(ii) \( A \) is a left co-Frobenius coalgebra.
(iii) \( A \) is a left QcF coalgebra.
(iv) \( A \) is a left semiperfect coalgebra.
(v) \( A \) has a non-zero right integral.
(vi) \( A \) is a right QcF coalgebra.
(vii) \( A \) is a right semiperfect coalgebra.
(ix) \( A \) is a generator in the category \( A^* \mathcal{M} \) (or in \( \mathcal{M}^A \)).
(x) \( A \) is a projective object in the category \( A^* \mathcal{M} \) (or in \( \mathcal{M}^A \)).

**Proof.** \((i) \Rightarrow (ii)\) Let \( T \in A^* \) be a non-zero left integral. We define a bilinear form \( b : A \otimes A \to k \) as follows:
\[
b(a, b) = \theta^*(T \otimes b)(a), \quad \forall a, b \in A, \quad (4.18)
\]
where \( \theta^* \) is the map defined as in (4.13). Then, for all \( a, b \in A \) and \( a^* \in A^* \) we compute:
\[
b(a \mapsto a^*, b) = \sum a^*(a_1) b(a_2, b) \quad (4.18) = \langle a^* \theta^*(T \otimes b), a \rangle \quad (4.14) (4.18) = \sum a^*(b_2) b(a, b_1) = b(a, a^* \mapsto b)
\]
proving that \( b \) is \( C^* \)-balanced. Now we prove that \( b \) is left non-degenerate. If \( x \in A \) such that \( b(a, x) = 0 \) for any \( a \in A \) then \( \theta(T \otimes x) = 0 \), and it follows from Proposition 3.2 that \( x = 0 \). Thus \( b \) is \( C^* \)-balanced and left non-degenerate, so \( A \) is a left co-Frobenius coalgebra.

By [8, Proposition 2.2], any subcoalgebra \( D \) of a left semiperfect coalgebra \( C \) is itself left semiperfect. As a consequence of Theorem 4.5, we therefore have

**Corollary 4.6** Let \( A \) be a dual quasi-Hopf algebra with non-zero integrals. Then any dual quasi-Hopf subalgebra \( B \) of \( A \) (i.e. a subcoalgebra \( B \) of \( A \) which is closed under multiplication of \( A \), \( 1 \in B \) and \( S(B) \subseteq B \)) has non-zero integrals.

We proceed with a proof of the uniqueness of integrals for dual quasi-Hopf algebras. First, by [7, Remark 5.4.3], if \( C \) is a left and right co-Frobenius coalgebra, and \( M \) is a finite dimensional right \( C \)-comodule, then \( \dim_k \text{Hom}_C(C, M) \leq \dim_k M \) (Recall that \( M \) and \( N \) are in a natural way left \( C^* \)-modules).

**Proposition 4.7** Let \( A \) be a dual quasi-Hopf algebra with non-zero integral. Then \( \dim_k f_I = \dim_k f_r = 1 \).

**Proof.** \( A \) is a left and right co-Frobenius dual quasi-Hopf algebra by Theorem 4.5, \( k \) is a right \( A \)-comodule, and \( f_r = \text{Hom}_A(A, k) \). Thus, \( f_r \) has dimension at most 1, so this has dimension precisely 1 since \( f_r \neq 0 \). Now, if we replace the dual quasi-Hopf algebra \( A \) with \( A^{\text{op, cop}} \) then we obtain that \( \dim_k f_I = 1 \).

A result of Radford [20] asserts that a co-Frobenius Hopf algebra has bijective antipode. It is not known if a similar result holds for a co-Frobenius dual quasi-Hopf algebra. To this end, we would need the dual version of Lemma 2.4 without the assumption that the antipode is bijective. However, we know that the antipode of a co-Frobenius dual quasi-Hopf algebra is injective (Corollary 4.4). We apply this to prove the following result:

**Lemma 4.8** Let \( A \) be a dual quasi-Hopf algebra with a non-zero left integral \( T \) and antipode \( S \). Then \( T \circ S \) is a non-zero right integral on \( A \). In particular, \( \overline{S}(f_I) = f_r \).

**Proof.** We omit the proof, since it is identical to proof of [7, Lemma 5.4.4].

The right integral \( T \circ S \) can be described more explicitly. Indeed, let \( A \) be a dual-quasi Hopf algebra with non-zero left integral \( T \). Then, for all \( a^* \in A^* \), \( Ta^* \) is also a left integral and \( Ta^* = \chi(a^*)T \) for some map \( \chi \) from \( A^* \) to \( k \). Since \( Ta^*b^* = \chi(a^*b^*)T = \chi(a^*)\chi(b^*)T \) and \( T = \chi(\varepsilon)T \), \( \chi \) is an algebra map. Let \( G(C) \) be the set of grouplike elements of a coalgebra \( C \). From (4.6) and (4.8), it follows that a grouplike element \( g \) in a dual quasi-Hopf algebra is invertible, and \( g^{-1} = S(g) \).

The following result generalizes [3, Proposition 1.3].

**Proposition 4.9** Let \( A \) be a dual quasi-Hopf algebra with a non-zero left integral \( T \). Then there exists a grouplike element \( g \) in \( A \) such that

(i) \( Ta^* = a^*(g)T \) for any \( a^* \in A^* \);

(ii) \( \overline{S}(T) = \Lambda(g \rightarrow T) \), where \( \Lambda \in A^* \) is given by \( \Lambda(b) = \sum \alpha(b_2)\Phi^{-1}(S(b_1), b_3, g) \) for all \( b \in A \).

**Proof.** Since \( T \neq 0 \), there exists \( a \in A \) such that \( T(a) = 1 \). We will show that \( g = a \mapsto T = \sum T(a_1)a_2 \)
has the required properties. As in Section 3, we denote by $\rightarrow$ and $\leftarrow$ the usual left and right action respectively of $A$ on $A^*$, that is
\[
\langle b \rightarrow a^*, c \rangle = \langle a^*, cb \rangle \quad \text{and} \quad \langle a^* \leftarrow b, c \rangle = \langle a^*, bc \rangle.
\]
It is easy to show that
\[
\langle a^*b^* \rangle \leftarrow b = \sum (a^* \leftarrow b_1)(b^* \leftarrow b_2); \quad (4.19)
\]
\[
b \rightarrow (a^*b^*) = \sum (b_1 \rightarrow a^*)(b_2 \rightarrow b^*). \quad (4.20)
\]
Let $\chi \in A^{**}$ be defined as above. For all $a^* \in A^*$, we have that
\[
\chi(a^*) = \chi(a^*)T(a) = \langle Ta^*, a \rangle = \sum T(a_1)a^*(a_2) = \langle a^*, \sum T(a_1)a_2 \rangle = a^*(g),
\]
and therefore $Ta^* = \chi(a^*)T = a^*(g)T$, for any $a^* \in A^*$. $g$ is a grouplike element, because $\chi$ is an algebra map.

(ii) Define $\Lambda : A \rightarrow A^*$ given by $\Lambda(b)(c) = \sum \alpha(b_2)q^{-1}(S(b_1), b_3, c)$ for any $b, c \in A$. It follows that $\Lambda(b) = \Lambda(b)(g)$, for any $b \in A$, and $\Lambda(1) = \varepsilon$. Moreover, by (4.1), (4.5) and (i) we have that
\[
\sum \Lambda(b_2)[(S \leftarrow S(b_1)) \leftarrow b_3] = T\Lambda(b) = \Lambda(b)T \quad \forall \ b \in B. \quad (4.21)
\]
Now, the relation in (ii) follows from the following computation, for all $b \in A$:
\[
\begin{align*}
\langle \Lambda(g \rightarrow T), b \rangle &= \sum \Lambda(b_1)[S \leftarrow b_2, g]T(a) \\
&= \sum \Lambda(b_1)[T \leftarrow b_2, a] \quad (4.21) \quad (4.19) \\
&= \sum \sum \langle \Lambda(b_2)\{[(S \leftarrow S(b_1))T] \leftarrow b_3\}, a \rangle \\
&= \sum T(S(b_1))\langle \Lambda(b_2)(T \leftarrow b_3), a \rangle \quad \text{since } T \in f_l \\
&= \langle \Lambda(1)T, a \rangle \langle S(T), b \rangle \quad \text{since } S(T) \in f_r, \text{ see Lemma 4.8} \\
&= \langle S(T), b \rangle.
\end{align*}
\]

We conclude this paper with a Maschke type theorem for dual quasi-Hopf algebras. Let $C$ be a coalgebra and $M$ a right $C$-comodule. Recall that $M$ is called cosemisimple if for any subcomodule $N$ of $M$ there exists a $C$-colinear map $\pi : M \rightarrow N$ such that $\pi \circ i = id$, where $i : N \rightarrow M$ is the inclusion map. $C$ is called cosemisimple if any right $C$-comodule is cosemisimple.

**Theorem 4.10** For a dual quasi-Hopf algebra $A$, the following statements are equivalent:

(i) $A$ is a cosemisimple coalgebra;

(ii) $A$, viewed as a right $A$-comodule via comultiplication, is cosemisimple as an $A$-comodule;

(iii) there exists a right integral $T \in A^*$ such that $T(1) = 1$;

(iv) there exists a left integral $T \in A^*$ such that $T(1) = 1$.
Proof. (i) ⇒ (ii). is trivial.

(ii) ⇒ (iii). Let \( u : k \to A \) be the unit map of \( A \). \( k \) is trivially a right \( A \)-comodule. Since \( u \) is injective there exists an \( A \)-colinear map \( T : A \to k \) such that \( T(1) = 1 \). This means that \( T \) is a right integral for \( A \) and \( T(1) = 1 \).

(iii) ⇒ (iv). Let \( T \) be a right integral on \( A \) such that \( T(1) = 1 \). Then \( T \) is a left integral on \( A^{\text{op,cop}} \) and \( T \circ S \) is a right integral on \( A^{\text{op,cop}} \), by Lemma 4.8. Therefore, \( T \circ S \) is a left integral for \( A \), and since \( T(1) = 1 \) it follows that \( (T \circ S)(1) = 1 \).

(iv) ⇒ (i). Let \( T \in \mathcal{H}_1 \) be such that \( T(1) = 1 \) and \( M \) a right \( A \)-comodule. Then \( M \otimes A \) is also a right \( A \)-comodule right \( A \)-action \( id \otimes \Delta \). \( \rho_M : M \to M \otimes A \) is an injective right \( A \)-colinear map. Moreover, the map \( \omega_M : M \otimes A \to M \) given by

\[
\omega_M(m \otimes a) = \sum \alpha(a_3)\varphi(m_{(1)}, S(a_2), a_4)\beta(m_{(3)})T(m_{(2)}S(a_1))m_{(0)},
\]

(4.22)
is right \( A \)-colinear (by (4.16)), and \( \omega_M \circ \rho_M = id \) (by (4.5) and (4.6)).

Now, if \( N \) is an \( A \)-subcomodule of \( M \), then there is a \( k \)-linear map \( \tilde{\pi} : M \to N \) such that \( \tilde{\pi} \circ i = id \), where \( i \) is the inclusion map \( i : N \to M \). We define \( \pi : M \to N, \pi = \omega_N \circ (\tilde{\pi} \otimes id) \circ \rho_M \), where \( \omega_N \) is the corresponding map (4.22) for the right \( A \)-comodule \( N \). It is not hard to see that \( \tilde{\pi} \otimes id \) is \( A \)-colinear, hence \( \pi \) is \( A \)-colinear. It also follows from the above considerations that \( \pi \circ i = id \), proving that \( A \) is a cosemisimple coalgebra.

ACKNOWLEDGEMENTS

The authors thank the referee for his helpful comments, which improved a first version of this paper. They also would like to thank Peter Schauenburg for telling them about his approach to quasi-bialgebras during Hopf algebra meetings held in Brussels and Toronto during the spring and fall of 2002.
