Vanishing point detection with convolutional neural networks

1. Introduction

In a graphical perspective, a vanishing point (VP) is a 2D point (in the image plane) which is the intersection of parallel lines in the 3D world (but not parallel to the image plane). In other words, the vanishing point is the spot to which the receding parallel lines diminish. In principle, there can be more than one vanishing point in the image. VP can commonly be seen in fields, railroads, streets, tunnels, forest, buildings, objects such as ladder (from looking bottom-up), etc. It is an important visual cue useful in several applications (e.g., camera calibration, 3D reconstruction, autonomous driving).

Inspired by the finding that vanishing point (road tangent) guides driver’s gaze [1, 2], in our previous work we showed that vanishing point attracts gaze during free viewing of natural scenes as well as in visual search [3]. We have also introduced improved saliency models using vanishing point detectors [4]. Here, we aim to predict vanishing points in naturalistic environments by training convolutional neural networks in an end-to-end manner.

2. Experiments & Results

2.1. Data collection

To train deep neural networks, often a large amount of data is needed. We resorted to YouTube to download videos including road trips across America (e.g., from sedan, bus, or truck dash cams), personal adventures (e.g., using shifters or motorbikes) or game playing sessions (e.g., formula one, Nascar). These videos have been captured in a variety of weather and ground conditions (e.g., freeway, race track, in city, inter city, snowy, rainy, sunny, mountainous, forest, vegetation). Eventually, we had 37,497 frames (resized to 300 × 300 pixels). We annotated vanishing points (1 per frame) in all videos (one annotator; the author). The grid cell containing the vanishing point has the label 1 on a \( n \times n \) grid map (\( n \in \{10, 20, 30\} \)). Some example frames of 29 YouTube videos are shown in Figure 1.

We also collected some images without VPs to train a binary classifier for VP existence prediction. A total of 32,419 images were sampled from these datasets: MIT saliency benchmark [6], CAT2000 dataset [7], Caltech 256 [8], 15 category dataset [9] except the street and highway categories, MS COCO [10], and Imagenet [11].

2.2. Vanishing point existence prediction

After training networks for 20 epochs over 63,916 images (34,497 with VP and 29,419 without VP), we obtained 98.9% VP existence prediction accuracy using the Alexnet network and 99.73% using the VGG network over the test set (6,000 images; 3,000 with VP).

2.3. Vanishing point localization

Alexnet and VGG networks were trained to map a scene into the VP location which is one of the \( p \) classes (\( p = 100, 400, \) or 900; linearized \( n \times n \) grids). Thus, there are \( p \) neurons in the output layers. We used 33,000 frames for training and the remaining 4,497 frames for testing. The network training was stopped after 40 epochs.

Results are shown in Figure 2. We achieved the lowest top-5 error rate of 5.1% over \( 10 \times 10 \), 15.9% over \( 20 \times 20 \), and 25.3% over \( 30 \times 30 \) grid sizes using the VGG network. It means that the probability of hitting within 15 pixels of the true VP location in 5 guesses is about 85% (over a 20 × 20 grid on a 300 × 300 image). Our results are nearly the same using both networks. Figure 2 (right) shows some success and failure cases of the Alexnet for VP localization.

Since vanishing point usually happens at the image center (See Figure 1, bottom-right), we devised two baseline predictors to further evaluate our method. The first one is the most frequent grid location (\( [x \ y] \) in training data) denoted as the ‘Top-1 center’ and the second one is the five most frequent locations (\( [x \ y], [x-1 \ y], [x \ y-1], [x+1 \ y], [x \ y+1] \); all set to one, the rest are zero) denoted as ‘Top-5 center’. These models perform well above chance (16.5% accuracy using Top-1 center vs. 0.25% chance over a 20 ×
Figure 1. Left: Two sample frames of each of 29 videos downloaded from YouTube. Top-right: Sample images without vanishing point used to train the vanishing point existence prediction network. Bottom-right: Average vanishing point location. Left panel shows all visited locations and the right panel shows the VP histogram.

Figure 2. Left: Error rates of deep models for VP detection. Top-right: Sample images where our model is able to accurately locate the VP in five tries. Red circle is the top-1 prediction and blue ones are the next top-4. Bottom-right: Failure examples of our model.

We also compare our model with two vanishing point detection algorithms from the literature. The first one is a method by Košecká and Zhang [12] and the second one is the classic Hough transform [5]. These two algorithms score 15.6% and 35%, respectively in detecting the vanishing point on a 20 × 20 map (Top-1 accuracy) which are much lower than our results using CNNs.

To assess the generalization power of our approach in detecting vanishing points in arbitrary natural scenes, we experimented with pictures of buildings, tunnels, sketches and fields shown in Figure 3. Although our model (VGG) has not been explicitly trained on these images, it successfully finds VPs in some of them. It fails on some other unseen examples (e.g., sketches). Augmenting our dataset with more images of these kinds could help overcome this shortcoming. Another way to improve performance would be through data augmentation (i.e., adding jittered, cropped, noisy, and blurry versions of input images).

3. Discussion

We proposed a method for vanishing point detection based on convolutional neural networks that does well on road scenes but is not very effective on arbitrary images. We will consider collecting a larger image dataset with variety of scenes including vanishing points and more recent deep learning architectures to improve accuracy. Extension of this approach to videos is another interesting future direction. Our dataset is freely available at: http://crcv.ucf.edu/people/faculty/Borji/code.php

Acknowledgments: We wish to thank NVIDIA for their generous donation of the GPU used in this study.
Figure 3. Performance of our vanishing point detector on arbitrary images containing vanishing points. The largest red circle is the first detection. Other four detections are shown in blue.
