Abstract

We analyze the global behaviour of the growth index of cosmic inhomogeneities in an isotropic homogeneous universe filled by cold non-relativistic matter and dark energy (DE) with an arbitrary (and not universal necessarily) equation of state. Using the dynamical system approach, we find the critical points of the system. That unique trajectory for which the growth index \(\gamma\) is finite from the asymptotic past to the asymptotic future is identified as the so-called heteroclinic orbit connecting the critical points \((\Omega_m = 0, \gamma_{\infty})\) in the future and \((\Omega_m = 1, \gamma_{-\infty})\) in the past. The first is an attractor while the second is a saddle point, confirming our earlier results. Further, in the case when a fraction of matter (or DE tracking matter) \(\varepsilon\Omega_{\text{tot}}^m\) remains unclustered, we find that the limit in the past \(\gamma_{-\infty}^\varepsilon\) does not depend on the equation of state of DE, in sharp contrast with the case \(\varepsilon = 0\). This is possible because the limits \(\varepsilon \to 0\) and \(\Omega_{\text{tot}}^m \to 1\) do not commute. The value \(\gamma_{-\infty}^\varepsilon\) corresponds to a solution with tracking DE, \(\Omega_m = 1 - \varepsilon, \Omega_{DE} = \varepsilon\) and \(w_{DE} = 0\) found earlier.

1 Introduction

The present accelerated expansion rate of the Universe remains an outstanding challenge for theoretical cosmology. Despite intensive ongoing activity, the nature of dark energy (DE) driving the present accelerated expansion stage (physical, geometrical, or both) and its relation to known particles and fields remain unsettled [1]. Many DE models inside, as well as outside, general relativity (GR) were suggested for this purpose. While the increasing accuracy of observations allow to rule out many of them, a large number still remains viable. Among the successful DE models, ΛCDM has a very particular place due to its remarkable simplicity: it is based on GR with cold non-relativistic matter as a source, and requires only the addition of a (cosmological) constant Λ into the Einstein equations. However, the attempt to interpret Λ in terms of ‘vacuum energy’ of quantum fields requires understanding why its effective energy density is so small compared to all other known substances. On the other hand, from the classical point of view, the ΛCDM is intrinsically consistent and its phenomenology serves as a benchmark for the interpretation of observational data and comparison to other DE models. Future observations will strongly constrain surviving models [2]. It is therefore important to have tools characterizing their phenomenology (see e.g. [3]). One such tool is the growth index γ.

The growth index has a nice property valid for ΛCDM and more generally for non-interacting smooth DE models inside GR [4]: up to a small correction depending on Ω_{m,0}, its value today γ₀ is well constrained, γ₀ ≈ 0.55. In addition, at higher redshifts it is quasi-constant (see also [5]). For example, in the presence of a cosmological constant Λ, γ tends to 6/11 for z ≫ 1 and it departs little from that value even up to the present time. Its discriminative power is therefore limited for these models. However modified gravity DE models can exhibit a strong departure from this behaviour [6], [7], [8]. The growth index offers therefore the possibility to discriminate between DE models inside and outside GR, motivating its study in the context of DE models. Hence, while the growth index was initially introduced in order to characterize the growth of matter perturbations for open Universes [9], and later generalized to other models inside GR [10], interest in the growth index was revived recently [6] for the assessment of DE models.

The study of the growth index is also of mathematical interest in its own. A global analysis of its dynamics, from deep in the matter era till the future DE dominated stage, often offers a better insight on its evolution including low redshift behavior probed by observations [11]. We will study in details a system with partially unclustered dust-like matter (or, DE tracking dust-like matter), showing interesting connections with results obtained earlier for a strictly constant growth index. We will also study the evolution of γ using the dynamical system analysis. We first review the basic formalism in the next section, as well as results and methods from our earlier work [11].

2 The growth index

In this section, we review the basic equations and definitions concerning the growth index γ. We consider the evolution of linear (dust-like) matter density perturbations δₘ = δρₘ/ρₘ on
cosmic scales. Deep inside the Hubble radius they obey the following equation

\[ \ddot{\delta}_m + 2H\dot{\delta}_m - 4\pi G\rho_m\delta_m = 0, \tag{1} \]

where \( H(t) \equiv \dot{a}(t)/a(t) \), resp. \( a(t) \), is the Hubble parameter, resp. the scale factor of a Friedmann-Lemaître-Robertson-Walker (FLRW) universe filled with standard dust-like matter and DE (we neglect radiation at the matter and DE dominated stages). We assume that DE remains non-clustered gravitationally at scales at which matter does.

For vanishing spatial curvature, we have for \( z \ll z_{eq} \)

\[ h^2(z) = \Omega_{m,0} (1 + z)^3 (1 - \Omega_{m,0}) \exp \left[ 3 \int_0^z dz' \frac{1 + w_{DE}(z')}{1 + z'} \right], \tag{2} \]

with \( h(z) \equiv \frac{H}{H_0} \), \( w_{DE}(z) \equiv p_{DE}(z)/\rho_{DE}(z) \), \( z = \frac{a_0}{a} - 1 \), and finally \( \Omega_{m,0} \equiv \frac{\rho_{m,0}}{\rho_{cr,0}} \). We do not assume \( w_{DE}(z) \) to be universal, i.e. independent of redshift and of initial conditions, though it has to be given anyway. Equality (2) holds for FLRW models inside GR and for many models beyond GR as well with appropriate definitions of the dark energy sector. We recall the definition \( \Omega_m = \Omega_{m,0} \frac{a^3}{a^2} h^{-2} \) and the useful relation

\[ w_{DE} = \frac{1}{3(1 - \Omega_m)} \frac{d \ln \Omega_m}{d \ln a}. \tag{3} \]

Introducing the growth function \( f \equiv \frac{d \ln \delta_m}{d \ln a} \) and using (3), equation (1) can be recast into the equivalent nonlinear first order equation [12]

\[ \frac{df}{dN} + f^2 + \frac{1}{2} \left( 1 - \frac{d \ln \Omega_m}{dN} \right) f = \frac{3}{2} \Omega_m, \tag{4} \]

with \( N \equiv \ln a \). Clearly, for constant \( p \), \( f = p \) if \( \delta_m \propto a^p \). Generically, this formalism is applied when the decaying mode is vanishingly small (see [11] for a more general approach).

The following parametrization has been intensively used and investigated in the context of dark energy

\[ f = \Omega_m(z)^{\gamma(z)}, \tag{5} \]

where \( \gamma \) is dubbed growth index, though generically \( \gamma(z) \) is a genuine function which can even depend on scales for modified gravity models. The representation (5) is a powerful tool in order to discriminate between DE models based on modified gravity theories and the ΛCDM paradigm.

In many DE models outside GR [13] the modified evolution of matter perturbations can be written as

\[ \ddot{\delta}_m + 2H\dot{\delta}_m - 4\pi G_{\text{eff}}\rho_m\delta_m = 0 \tag{6} \]

at sufficiently small scales exceeding the effective 'Jeans' scale for cold matter but much smaller than the Hubble one, where \( G_{\text{eff}} \) is some effective gravitational coupling appearing in the model. For example, for effectively massless scalar-tensor models [14], \( G_{\text{eff}} \) is varying with time but
it has no scale dependence, while its value today is equal to the usual Newton’s constant \( G \). Introducing for convenience the quantity

\[
g \equiv \frac{G_{\text{eff}}}{G},
\]

we easily get from (6) the modified version of Eq. (4), viz.

\[
\frac{df}{dN} + f^2 + \frac{1}{2} \left( 1 - \frac{d \ln \Omega_m}{dN} \right) f = \frac{3}{2} g \Omega_m,
\]

where the same GR definition \( \Omega_m = \frac{8 \pi G \rho_m}{3 H^2} \) is used. Some subtleties can arise if the defined energy density of DE becomes negative. For a strictly constant growth index \( \gamma \), it is straightforward to deduce from (8) that \( w_{DE} = \bar{w} \) with

\[
\bar{w} = -\frac{1}{3(2\gamma - 1)} \frac{1 + 2\Omega_\gamma - 3g\Omega_m^{1-\gamma}}{1 - \Omega_m}.
\]

(9)

\[
\equiv -\frac{1}{3(2\gamma - 1)} F(\Omega_m; g, \gamma).
\]

(10)

The case \( g = 1 \) reduces to GR and we will simply write

\[
F(\Omega_m; g = 1, \gamma) \equiv F(\Omega_m; \gamma).
\]

(11)

Below, for a quantity \( v, v_\infty \), resp. \( v_{-\infty} \), will denote its (limiting) value for \( x \to \infty \) in the DE dominated era (\( \Omega_m \to 0 \)), resp. \( x \to -\infty \) (generically \( \Omega_m \to 1 \)). We have in particular from (9) for \( g = 1 \) (GR)

\[
\gamma = \frac{3\bar{w}_\infty - 1}{6\bar{w}_\infty}
\]

(12)

\[
\gamma = \frac{3(1 - \bar{w}_{-\infty})}{5 - 6\bar{w}_{-\infty}}.
\]

(13)

We assume \( \bar{w} < 0 \) to get matter domination in the past and DE domination in the future. Eq.(12) requires further \( \bar{w}_\infty < -\frac{1}{3} \) in order to have \( 0 < \gamma < 1 \), otherwise \( \bar{w}_\infty \) becomes infinite.

It was found in [5] that these relations between a constant \( \gamma \) and the corresponding asymptotic values \( \bar{w}_\infty \) and \( \bar{w}_{-\infty} \) apply also for the dynamical \( \gamma \) obtained for an arbitrary but given \( w_{DE} \). In the latter case, we obtain for \( g = 1 \)

\[
\gamma_\infty = \frac{3w_\infty - 1}{6w_\infty}
\]

(14)

\[
\gamma_{-\infty} = \frac{3(1 - w_{-\infty})}{5 - 6w_{-\infty}},
\]

(15)

with \( w_\infty \), resp. \( w_{-\infty} \), the asymptotic value of \( w_{DE} \) in the future, resp. past. This nice property can actually be generalized to modified gravity models [11].
Taking $\Omega_m$ as the integration variable, the evolution equation for $\gamma$ obtained from (8) using (5) yields
\begin{equation}
2\alpha \Omega_m \ln(\Omega_m) \frac{d\gamma}{d\Omega_m} + \alpha(2\gamma - 1) + F(\Omega_m; g, \gamma) = 0 ,
\end{equation}
where we have defined
\begin{equation}
\alpha \equiv 3w_{DE} .
\end{equation}
The solutions to equation (16) on the entire $\Omega_m$ interval is the envelope of its tangent vectors
\begin{equation}
\left( \frac{1}{d\gamma/d\Omega_m} \right) .
\end{equation}
All these tangent vectors define a vector field that can be written
\begin{equation}
\left( \begin{array}{c}
2\alpha \Omega_m(1 - \Omega_m) \ln(\Omega_m) \\
-\alpha(2\gamma - 1)(1 - \Omega_m) - \tilde{F}(\Omega_m; \gamma)
\end{array} \right) .
\end{equation}
where we have defined
\begin{equation}
\tilde{F}(\Omega_m; g, \gamma) \equiv (1 - \Omega_m)F(\Omega_m; g, \gamma) = 1 + 2\Omega_m^1 - 3g\Omega_m^{1-\gamma} .
\end{equation}
We write the vector field in this way in order to have explicitly regular functions everywhere for $(\Omega_m, \gamma) \in [0, 1] \times \mathbb{R}$. One obtains the integral curves of this vector field (i.e. the phase portrait) by solving the autonomous differential system
\begin{align}
\frac{d\Omega_m}{ds} &= 2\alpha \Omega_m(1 - \Omega_m) \ln(\Omega_m) \\
\frac{d\gamma}{ds} &= -\alpha(2\gamma - 1)(1 - \Omega_m) - \tilde{F}(\Omega_m; \gamma)
\end{align}
where $s \in \mathbb{R}^+$ is a dummy variable parametrizing the curves. Clearly, the trajectories $\gamma(\Omega_m)$ are not unique. Only one integral curve however is finite everywhere: for $\Lambda$CDM, it is the curve $\gamma(\Omega_m)$ which starts (in the past) at $\gamma(1) \equiv \gamma_{-\infty} = 6/11$ and ends (in the future) at $\gamma(0) \equiv \gamma_{\infty} = 2/3$. It corresponds to the presence solely of the growing mode of Eq.(1), or equivalently to the limit of a vanishing decaying mode. For cosmological constraints on DE models, one is essentially interested in that unique trajectory corresponding to a vanishing decaying mode. It is the only trajectory which has a finite initial condition $\gamma_{-\infty}$ at $\Omega_m = 1$, for all other trajectories $\gamma$ will diverge in the past. However, concerning the asymptotic future ($\Omega_m \to 0$), inside GR the solution to Eq. (16) gives $\gamma \to \gamma_{\infty}$, Eq. (12), with $(w_{\infty} < -\frac{1}{3})$
\begin{equation}
f \propto Ca^{\frac{1}{2}(1-3w_{\infty})} \to 0 .
\end{equation}
The crucial point is that this asymptotic behaviour is identical for all cases where the decaying mode is present, up to a change of the prefactor in (19) which depends on initial conditions and on the amplitude of the decaying mode with respect to the growing mode. Taking into account that $\Omega_m \sim a^{3w_{\infty}}$, it is straightforward to obtain from Eq. (5) that
\begin{equation}
\gamma = \frac{\ln f}{\ln \Omega_m} \to \gamma_{\infty}
\end{equation}
for all curves. This is complementary to the results obtained in [15], where the growing mode for models beyond GR was considered.
3 Dynamical system approach

In this section, we will study our equations using the dynamical system approach. While the introduction of the variable $\Omega_m$ is natural for a global analysis of the evolution of the growth index $\gamma$, we use the integration variable $N \equiv \ln a$ (equivalently $x = a/a_0$) for the dynamical system approach, and we obtain for $g = 1$ (GR)

$$2 \ln(\Omega_m) \frac{d\gamma}{dN} + \alpha(2\gamma - 1)(1 - \Omega_m) + \tilde{F}(\Omega_m; \gamma) = 0. \quad (21)$$

This is equivalent to the following differential system

$$\frac{d\Omega_m}{dN} = \Omega_m(1 - \Omega_m)\alpha \quad (22)$$
$$\frac{d\gamma}{dN} = -\frac{\alpha(2\gamma - 1)(1 - \Omega_m) + \tilde{F}(\Omega_m; \gamma)}{2 \ln(\Omega_m)}. \quad (23)$$

We will use these equations in order to find the critical (or stationary) points of our system satisfying $\frac{d\Omega_m}{dN} = 0$, $\frac{d\gamma}{dN} = 0$. Note that Eq. (22) is independent of $\gamma$ and can therefore be integrated independently. When the function $\alpha(a) \equiv 3w_{DE}(a)$ is known, we can obtain $\alpha(\Omega_m)$ using (3).

We find readily from (22) that $\frac{d\Omega_m}{dN} = 0$ in the following three cases: $\Omega_m = 0$, $\Omega_m = 1$, $\alpha(\Omega_m) = 0$. The stability of a dynamical system is given by the Hartman-Grobman theorem which asserts that there is a certain $2 \times 2$ matrix whose eigenvalues characterize the behavior of the system around the critical points. For the critical point corresponding to $\Omega_m = 1$

$$\begin{pmatrix} \Omega_m = 1, \gamma = \gamma_{-\infty} \end{pmatrix}, \quad (24)$$

we find that the eigenvalues of our system are $(-2\alpha_{-\infty}, 2\alpha_{-\infty} - 5)$ and therefore the critical point is a saddle point for $\alpha_{-\infty} \leq 0$. For the critical point corresponding to $\Omega_m = 0$

$$\begin{pmatrix} \Omega_m = 0, \gamma = \gamma_{\infty} \end{pmatrix}, \quad (25)$$

the eigenvalues of the linearized system are $(\alpha_{\infty}, 0)$ and therefore we conclude that it is an attractor for $\alpha_{\infty} \leq 0$. Notice that the zero eigenvalue does not point to any stability or instability, but a simple centre manifold analysis allows us to conclude about the stability of the critical point. To study the structure of the phase space at infinity, we define $u = 1/\gamma$. We obtain that $u = 0$ ($\gamma = \pm \infty$) is also a critical point and it is easy to show that $u = 0$ is a repeller. These results of the dynamical system analysis confirm the asymptotic properties found analytically and numerically in [11] and summarized in Section 2.

The remaining critical points correspond to $\alpha(\Omega_m) = 0$ and $\tilde{F} = 0$. Indeed, various critical points can exist if $\alpha(\Omega_m)$ has different zeroes. These critical points can have a richer structure. The eigenvalues associated to this system are $(-2\Omega_m^{\gamma} - 1/2, \Omega_m(1 - \Omega_m)\alpha'(\Omega_m))$. If $\frac{d\alpha}{d\Omega_m} \equiv \alpha'(\Omega_m) < 0$, the critical point is an attractor, if $\alpha'(\Omega_m) > 0$, the critical point is a saddle point. In particular for constant $\gamma$, these critical points correspond to the family of tracking
Figure 1: The phase portrait corresponding to the system of Eqs. (22), (23). We have an attractor at \((\Omega_m = 0, \gamma_\infty)\), a saddle point at \((\Omega_m = 1, \gamma_{-\infty})\) and the infinity which is a repeller. The red line corresponds to the trajectory connecting the 2 critical points (known as an heteroclinic orbit) while the red dotted lines connects infinity to the attractor. This phase portrait illustrates nicely the asymptotic properties of the trajectories presented in Section 2.

DE solutions for \(\Omega_m < 1\) and \(\bar{F} = 0\) found in [5]. As \(\frac{d\rho_m}{d\Omega_m} > 0\) in this case, our calculations confirm that these critical points correspond to saddle points. In the simpler (and generic) case where \(\alpha\) has no zeroes \((\alpha < 0)\), we can sketch the evolution of the system in the phase space \((\Omega_m, \gamma)\). (Fig. (1)). We see from Fig. (1), the existence of a special orbit, known as an heteroclinic orbit which connects the 2 critical points. Because it follows the repelling direction of the saddle point, it is easy to find from the eigenvector of the linearized system the behavior of this orbit around the critical point at \(\Omega_m = 1\) and one obtains

\[
\gamma = \gamma_{-\infty} + \frac{(\alpha_{-\infty} - 2)(\alpha_{-\infty} - 3) + 2\alpha_{-\infty}'(2\alpha_{-\infty} - 5)}{2(5 - 4\alpha_{-\infty})(5 - 2\alpha_{-\infty})^2} \left((1 - \Omega_m) + \mathcal{O}\left((1 - \Omega_m)^2\right)\right). \tag{26}
\]

This line is the asymptote of the heteroclinic orbit. Note that (26) generalizes the result given in [3] for constant \(\alpha\). One checks easily that \(\Lambda\)CDM satisfies indeed (26).

Because we consider a dynamical system (system of first order differential equations), the trajectories (orbits) in phase space cannot intersect. But of course other curves which are not orbits of the system can intersect these orbits, e.g. we can consider the curve for which \(\frac{d\gamma}{dN} = 0\) everywhere. For \(\alpha < 0\), it satisfies \(\frac{d\gamma}{d\Omega_m} = 0\) for \(0 < \Omega_m < 1\) and goes through the endpoints \(\gamma_{-\infty}\), resp. \(\gamma_\infty\), at \(\Omega_m = 1\), resp. \(\Omega_m = 0\). from eqs. (24), (25). So it corresponds to the curve dubbed \(\Gamma(\Omega_m)\) in [5]. It satisfies \(\overline{\Gamma}(\Omega_m), \Gamma(\Omega_m) = w_{DE}(\Omega_m)\) and we have indeed \(\Gamma(1) = \gamma_{-\infty}\) and \(\Gamma(0) = \gamma_\infty\). For arbitrary \(w_{DE}\), \(\gamma\) is not constant and hence \(\Gamma(\Omega_m)\) is not constant either. As \(\Gamma\) satisfies by construction \(\frac{d\gamma}{dN} = 0\) and critical points are defined by \(\frac{d\gamma}{dN} = 0, \frac{d\Omega_m}{dN} = 0\), \(\Gamma\)
must intersect the critical points, but of course it can also intersect orbits at points which are not critical points.

We can ask if it is above or under the heteroclinic orbit that we previously defined because they start and end at the same points. A global analysis is impossible, but we can at least analyze the behavior around $\Omega_m = 1$. We have already found the tangent to the heteroclinic orbit (see Eq. 26). We can also calculate the tangent to $\Gamma$ and we find around $\Omega_m = 1$

$$
\Gamma = \gamma_{-\infty} + \frac{(\alpha_{-\infty} - 2)(\alpha_{-\infty} - 3) + 2\alpha'_{-\infty}(2\alpha_{-\infty} - 5)}{2(5 - 2\alpha_{-\infty})^3}(1 - \Omega_m) + \mathcal{O}\left((1 - \Omega_m)^2\right). \tag{27}
$$

Therefore $\Gamma$ lies above the heteroclinic orbit iff

$$
\alpha'_{-\infty} < \frac{(\alpha_{-\infty} - 2)(\alpha_{-\infty} - 3)}{10 - 4\alpha_{-\infty}}. \tag{28}
$$

One checks easily that ΛCDM satisfies (28).

These results can be easily generalized to modified gravity for which the system becomes

$$
\frac{d\Omega_m}{dN} = \alpha(1 - \Omega_m)\Omega_m \tag{29}
$$

$$
\frac{d\gamma}{dN} = -\frac{\alpha(2\gamma - 1)(1 - \Omega_m) + \tilde{F}(\Omega_m; g, \gamma)}{2 \ln(\Omega_m)} \tag{30}
$$

We recover the same critical points as in GR if $g = 1$. Note that $g_{-\infty} = 1$ and $\left(\frac{dg}{dN}\right)_{-\infty} = 0$ in order to avoid that $w_{-\infty}$ becomes singular [5]. The coordinate of the critical point at $\Omega_m = 1$ changes into

$$
\left(\Omega_m = 1, \gamma = \frac{\alpha_{-\infty} - 3 - 3g'_{-\infty}}{2\alpha_{-\infty} - 5}\right). \tag{31}
$$

As expected, the expression for $\gamma$ in Eq. (31) corresponds to the only finite value in the asymptotic past found earlier [11]. Finally, we can also find the condition for which the curve $\Gamma$ starts at $\Omega_m = 1$ with an inclination larger than that of the heteroclinic orbit, viz.

$$
\alpha'_{-\infty} < \frac{(\alpha_{-\infty} - 2)(\alpha_{-\infty} - 3)}{10 - 4\alpha_{-\infty}} + \frac{3}{2}g''_{-\infty}(2\alpha_{-\infty} - 5) \tag{32}
$$

$$
+ 3g'_{-\infty}\frac{33 - 28\alpha_{-\infty} + 6\alpha_{-\infty}^2 - 27g'_{-\infty} + 12\alpha_{-\infty}g'_{-\infty} - 6(5 - 2\alpha_{-\infty})^2g''_{-\infty}}{2(2\alpha_{-\infty} - 5)(6g''_{-\infty} + 1)}. \tag{33}
$$

When we apply this equation to the Dvali-Gabadadze-Porrati (DGP) model [16] ($g'_{-\infty} = \frac{1}{3}$), it is found that the inequality (33) is satisfied. Hence the heteroclinic orbit in the DGP model is a decreasing function of $\Omega_m$ in the neighbourhood of $\Omega_m = 1$. This contrasts with the general shape of the heteroclinic orbit in the DGP model: it is an increasing function of $\Omega_m$ except for $\Omega_m \lesssim 10^{-3}$ and $\Omega_m \gtrsim 0.9$, the latter decrease (in the asymptotic past) is very tiny as compared to the sharp decrease in the asymptotic future [11].
4 Presence of an unclustered dust-like component

We consider yet another case inside GR where the growth index $\gamma(\Omega_m)$ is not monotonically decreasing in contrast to $\Lambda$CDM. Let us note first that in the particular case where $\Omega_m$ is constant, we readily get from (4)

$$f' + f^2 + \frac{1}{2} f - \frac{3}{2} C = 0,$$  \hspace{1cm} (34)

and we set $\Omega_m = C$ to emphasize the constancy of $\Omega_m$. Equation (34) has two constant solutions

$$p_1 = -\frac{1}{4} + \frac{1}{4} \sqrt{1+24C}, \quad p_2 = -\frac{1}{4} - \frac{1}{4} \sqrt{1+24C}.$$  \hspace{1cm} (35)

For $C > 0$, we have necessarily $p_1 > 0$ and $p_2 < 0$. In other words, there are two genuinely growing and decaying modes for $\delta_m$. When $C = 1$ we recover the standard results in an Einstein-de Sitter universe.

An interesting situation arises when dust-like matter has some (small) relative fraction $\Omega_x$ which does not cluster and only usual matter denoted by $\Omega_m$ does, with

$$\Omega^\text{tot}_m \equiv \Omega_m + \Omega_x = 1.$$  \hspace{1cm} (36)

This unclustered component can be also DE tracking matter exactly, i.e. having the effective equation of state $w_{DE} = 0$ at this stage. Then Eq.(34) is obtained with $C = \Omega_m < 1$. Let us consider for concreteness the situation with $\Omega_x \ll 1$. From (35) the growing mode scales $\propto a^{p_1}$ with

$$p_1 \approx 1 - \frac{3}{5} \Omega_x \approx \Omega^\text{35}_m.$$  \hspace{1cm} (37)

The last term in (37) makes contact with the growth index $\gamma$. In the case under consideration, both $\Omega_m$ and $f = p_1 > 0$ are constant, hence $\gamma$ is constant, too, and from (37) it is close to $\frac{3}{5}$ (see the nice discussion in [17]).

In [5], a family of solutions with constant $\gamma > \frac{3}{5}$ was found corresponding to the roots of $F(\Omega_m; \gamma)$ for $\Omega_m < 1$ with $\overline{w} = 0$ so that $\Omega_m$ remains constant. This corresponds to our system with $\overline{w} = w_x$. For $\Omega_x \ll 1$ it was found [5]

$$p_1 = \Omega^\text{35}_m(1+\frac{w_x}{2})$$  \hspace{1cm} (38)

when we expand $\gamma$ up to first order in $\Omega_x$. We see that (38) refines the result (37) (see also [6, 12]). We now extend these results to a universe where the expansion is driven also by an additional non-tracking (genuine) dark energy component so that $\Omega_m$ is no longer constant.

Using for convenience the variable $\Omega^\text{tot}_m$ instead of $\Omega_m$, the growth index satisfies the equation

$$\left[2 \Omega^\text{tot}_m \ln \left((1-\varepsilon)\Omega^\text{tot}_m\right) \frac{d\gamma^\varepsilon}{d\Omega^\text{tot}_m} + (2\gamma^\varepsilon - 1) \right] \alpha(1 - \Omega^\text{tot}_m) + \tilde{F}((1-\varepsilon)\Omega^\text{tot}_m; \gamma^\varepsilon) = 0,$$  \hspace{1cm} (39)

with

$$\Omega_{DE} = 1 - \Omega^\text{tot}_m, \quad \Omega_m = (1-\varepsilon)\Omega^\text{tot}_m, \quad \Omega_x = \varepsilon \Omega^\text{tot}_m.$$  \hspace{1cm} (40)
and we have noted $\gamma^\varepsilon(\Omega_{\text{tot}}^m)$ the solution of Eq. (39) for $\varepsilon > 0$.

In the asymptotic past, $\Omega_{DE} \to 0$, (39) becomes

$$-6 \ w_{-\infty} \ln(1 - \varepsilon) \frac{d \gamma^\varepsilon}{d \ln(1 - \Omega_{\text{tot}}^m)} + \tilde{F}(1 - \varepsilon; \gamma^\varepsilon) = 0 .$$

(41)

It is seen from (41) that any finite solution $\gamma^\varepsilon$ of (39) must tend in the past to the root of $\tilde{F}(1 - \varepsilon; \gamma)$, viz.

$$\tilde{F}(1 - \varepsilon; \gamma^\varepsilon_{-\infty}) = 0 ,$$

(42)

with $\gamma^\varepsilon_{-\infty} \equiv \gamma^\varepsilon(\Omega_{\text{tot}}^m \to 1)$.

Considering the change of variable, $X = (1 - \varepsilon) \gamma^\varepsilon_{-\infty}$, the Eq.(42) transforms into

$$2X^2 + X - 3(1 - \varepsilon) = 0$$

(43)

whose solutions are

$$X_{\pm} = \frac{-1 \pm \sqrt{25 - 24\varepsilon}}{4}$$

(44)

Considering only the positive root, we get

$$\gamma^\varepsilon_{-\infty} = \frac{\ln\left(\frac{-1+\sqrt{25-24\varepsilon}}{4}\right)}{\ln(1 - \varepsilon)}$$

(45)

So we get up to first order in $\varepsilon$

$$\gamma^\varepsilon_{-\infty} \simeq \frac{3}{5} \left(1 + \frac{\varepsilon}{25}\right) .$$

(46)

We note the intriguing property that $\gamma^\varepsilon_{-\infty}$ does not depend on any nonzero $w_{-\infty}$. In order to understand this, we consider the corresponding vector field $\mathcal{F}[\Omega_{\text{tot}}^m, \gamma^\varepsilon; \varepsilon]$ tangent to the solutions $\gamma^\varepsilon$

$$\mathcal{F}[\Omega_{\text{tot}}^m, \gamma^\varepsilon; \varepsilon] = \begin{pmatrix} 2\alpha \Omega_{\text{tot}}^m (1 - \Omega_{\text{tot}}^m) \ln((1 - \varepsilon)\Omega_{\text{tot}}^m) \\ -\alpha (2\gamma^\varepsilon - 1)(1 - \Omega_{\text{tot}}^m) - \tilde{F}'((1 - \varepsilon)\Omega_{\text{tot}}^m, \gamma^\varepsilon) \end{pmatrix}$$

(47)

and to look for its streamlines as we have done in Section 3. For $\Omega_{\text{tot}}^m \simeq 1$ and $\varepsilon \simeq 0$, we can write the vector field (47) to leading order

$$\mathcal{F}[\Omega_{\text{tot}}^m, \gamma^\varepsilon; 0] \simeq \begin{pmatrix} (\Omega_{\text{tot}}^m - 1) \varepsilon 6w_{-\infty} \\ (\Omega_{\text{tot}}^m - 1) [(6w_{-\infty} - 5)\gamma^\varepsilon - 3w_{-\infty} + 3] + \varepsilon(3 - 5\gamma^\varepsilon) \end{pmatrix}$$

(48)

It is seen that the leading order of the upper component $\left(\frac{d\Omega_{\text{tot}}^m}{ds}\right)$ is of order $(\Omega_{\text{tot}}^m - 1) \times \varepsilon$ in the small parameters $(\Omega_{\text{tot}}^m - 1)$ and $\varepsilon$. In the lower component $(\frac{d\gamma}{ds})$, we have neglected all higher order terms. For $\varepsilon = 0$ ($\Omega_x = 0$), in the neighbourhood of $\Omega_{\text{tot}}^m = 1$, we obtain to leading order in $\Omega_{\text{tot}}^m (\Omega_x = \Omega_{\text{tot}}^m)$

$$\mathcal{F}[\Omega_{\text{tot}}^m, \gamma; 0] \simeq \begin{pmatrix} 0 \\ (\Omega_{\text{tot}}^m - 1) [(6w_{-\infty} - 5)\gamma_{-\infty} - 3w_{-\infty} + 3] \end{pmatrix} ,$$

(49)
with
\[ \gamma_{-\infty} \equiv \gamma(\Omega_m^\text{tot} \to 1, \varepsilon = 0). \] (50)

To avoid that \( \frac{d\gamma}{d\Omega_m^\text{tot}} \big|_{\varepsilon=0} \) diverges in the neighborhood of \( \Omega_m^\text{tot} = 1 \), the lower component of \( \mathcal{F}[\Omega_m^\text{tot} \simeq 1, \gamma; \varepsilon = 0] \) must vanish too and hence we get
\[ \gamma_{-\infty} = \frac{3w_{-\infty} - 3}{6w_{-\infty} - 5}, \] (51)
so we recover the (expected) result, Eq.(15). On the other hand, for \( \varepsilon > 0 \) fixed and however small, from (48) the limit \( \Omega_m^\text{tot} \to 1 \) gives to leading order in the small parameter \( \varepsilon \)
\[ \mathcal{F}[\Omega_m^\text{tot} \to 1, \gamma^\varepsilon; \varepsilon] \simeq \begin{pmatrix} 0 \\ \varepsilon (-5\gamma_{-\infty} + 3) \end{pmatrix}. \] (52)
We obtain now \( \frac{3}{5} \) to lowest order in \( \varepsilon \), viz.
\[ \gamma_{-\infty}^\varepsilon = 3/5 + O(\varepsilon), \] (53)
in agreement with (37), (38). Actually, if we take the limit \( \Omega_m^\text{tot} \to 1 \) in (17), without expanding in \( \varepsilon \), we obtain
\[ \mathcal{F}[\Omega_m^\text{tot} \to 1, \gamma^\delta; \delta] \simeq \begin{pmatrix} 0 \\ -\tilde{F}(1 - \varepsilon; \gamma^\delta_{-\infty}) \end{pmatrix}, \] (54)
showing again that \( \gamma^\delta_{-\infty} \) must be a root of \( \tilde{F}(1 - \varepsilon; \gamma) \), and the value \( \frac{3}{5} \) obtained from (52) is just the lowest order of the expansion of \( \gamma^\delta_{-\infty} \) in powers of \( \varepsilon \).

Interestingly, there is another situation where an identical result appears [5]. Let us assume that we have a two-component system (\( \varepsilon = 0 \)) with \( \Omega_m^\text{tot} = \Omega_m \to 1 - \delta, \Omega_{DE} \to \delta \). This is possible only if DE behaves asymptotically like dust, \( w_{-\infty} = 0 \). If we take \( \delta > 0 \), we have from (17) in analogy with (34)
\[ \mathcal{F}[1 - \delta, \gamma^\delta_{-\infty}; \delta] \simeq \begin{pmatrix} 0 \\ -\tilde{F}(1 - \delta; \gamma^\delta_{-\infty}) \end{pmatrix}, \] (55)
which is just (54) with \( \varepsilon \) replaced by \( \delta \). So in this case, the small parameter that goes to zero is \( w \) instead of \( 1 - \Omega_m^\text{tot} \) previously.

To summarize, the system with a small amount of unclustered dustlike component is not continuous in the variables \( (\Omega_m^\text{tot}, \varepsilon) \) at \( \Omega_m^\text{tot} = 1, \varepsilon = 0 \) and taking the limit is affected by the order in which it is taken, viz
\[ \lim_{\varepsilon \to 0} \gamma^\varepsilon_{-\infty} \equiv \lim_{\varepsilon \to 0} \gamma^\varepsilon(\Omega_m^\text{tot} \to 1) \neq \lim_{\Omega_m \to 1} \gamma(\Omega_m) \equiv \gamma_{-\infty}. \] (56)
This explains why it is possible that \( \gamma^\varepsilon_{-\infty} \) does not depend on \( w_{-\infty} \). We recover consistently from (17) that for \( \varepsilon = 0, \Omega_m^\text{tot} = \Omega_m \to 1 - \delta \neq 1, w_{-\infty} = 0 \) (tracking DE), roots of \( \tilde{F}(1 - \delta; \gamma) \) yield the tracking DE solutions with a constant growth index \( \gamma \) found in [7].
In order to evaluate the derivative of $\gamma^\varepsilon(\Omega^\text{tot}_m)$ with respect to $\Omega^\text{tot}_m$ at $\Omega^\text{tot}_m = 1$, let us assume $\gamma^\varepsilon(\Omega^\text{tot}_m)$ is analytic with respect to $\Omega^\text{tot}_m$ and use an expansion at second order in $(\Omega^\text{tot}_m - 1)$, viz.

$$
\gamma^\varepsilon(\Omega^\text{tot}_m) = \gamma_{-\infty}^\varepsilon + \left. \frac{d\gamma^\varepsilon}{d\Omega^\text{tot}_m} \right|_{-\infty} (\Omega^\text{tot}_m - 1) + \frac{1}{2} \left. \frac{d^2\gamma^\varepsilon}{d(\Omega^\text{tot}_m)^2} \right|_{-\infty} (\Omega^\text{tot}_m - 1)^2 + \mathcal{O}((\Omega^\text{tot}_m - 1)^3)
$$

For simplicity, we denote

$$
\gamma_\Omega \equiv \left. \frac{d\gamma^\varepsilon}{d\Omega^\text{tot}_m} \right|_{-\infty}, \quad \gamma_{\Omega\Omega} \equiv \left. \frac{d^2\gamma^\varepsilon}{d(\Omega^\text{tot}_m)^2} \right|_{-\infty}.
$$

The derivative $\frac{d\gamma^\varepsilon}{d\Omega^\text{tot}_m}$ has therefore the following expansion up to first order

$$
\frac{d\gamma^\varepsilon}{d\Omega^\text{tot}_m} = \gamma_\Omega + \gamma_{\Omega\Omega}(\Omega^\text{tot}_m - 1)
$$

Let us use this expansion in $\mathcal{F}[\Omega^\text{tot}_m, \gamma; \varepsilon]$ and compute the ratio of the components, which then gives the derivative $\left. \frac{d\mathcal{F}}{d\Omega^\text{tot}_m} \right|_{-\infty}$. We will assume here that $\alpha$ is constant. The first component is

$$
2\alpha \Omega^\text{tot}_m (1 - \Omega^\text{tot}_m) \ln\left((1 - \varepsilon)\Omega^\text{tot}_m\right) = -2\alpha \left[\ln(1 - \varepsilon)(\Omega^\text{tot}_m - 1) + (\ln(1 - \varepsilon) + 1)(\Omega^\text{tot}_m - 1)^2\right],
$$

while the second component is

$$
-\alpha (2\gamma^\varepsilon - 1)(1 - \Omega^\text{tot}_m) - \tilde{\mathcal{F}}\left(\Omega^\text{tot}_m, \gamma; \varepsilon\right) = \gamma_{\text{tot}} + \gamma_\Omega (\Omega^\text{tot}_m - 1) + 1/2 \gamma_{\Omega\Omega} (\Omega^\text{tot}_m - 1)^2
$$

$$
\equiv f_0(\varepsilon) + f_1(\varepsilon)(\Omega^\text{tot}_m - 1) + f_2(\varepsilon)(\Omega^\text{tot}_m - 1)^2 + \ldots
$$

Considering $\Omega^\text{tot}_m = 1$, it is trivial to find

$$
-\tilde{\mathcal{F}}\left(\varepsilon; \gamma_{\text{tot}}\right) = f_0(\varepsilon)
$$

and using Eq. (52), we obtain $f_0(\varepsilon) = 0$. We have further

$$
f_1(\varepsilon) = \alpha (2\gamma^\varepsilon_{-\infty} - 1) - 2(1 - \varepsilon)\gamma^\varepsilon_{-\infty}(\gamma^\varepsilon_{+\infty} + \gamma_\Omega \ln(1 - \varepsilon)) - 3(1 - \varepsilon)^{1-\gamma^\varepsilon_{-\infty}}(\gamma^\varepsilon_{-\infty} + \gamma_\Omega \ln(1 - \varepsilon) - 1)
$$

$$
f_2(\varepsilon) = 2\alpha \gamma_\Omega - 3(1 - \varepsilon)^{1-\gamma^\varepsilon_{-\infty}} \times
$$

$$
\left(\gamma_\Omega + \frac{1 + (-\gamma^\varepsilon_{-\infty} + \gamma_{\Omega\Omega} \ln(1 - \varepsilon)) - (-1 + \gamma^\varepsilon_{-\infty} + \gamma_\Omega \ln(1 - \varepsilon))^2}{2}\right)
$$

$$
- 2(1 - \varepsilon)^{\gamma^\varepsilon_{-\infty}} \left(\gamma_\Omega + \frac{-\gamma^\varepsilon_{-\infty} + \gamma_{\Omega\Omega} \ln(1 - \varepsilon) + (\gamma^\varepsilon_{-\infty} + \gamma_\Omega \ln(1 - \varepsilon))^2}{2}\right)
$$

The derivative $\frac{d\gamma}{d\Omega^\text{tot}_m}$ is therefore given by

$$
\frac{f_0(\varepsilon) + f_1(\varepsilon)(\Omega^\text{tot}_m - 1) + f_2(\varepsilon)(\Omega^\text{tot}_m - 1)^2}{-2\alpha \ln(1 - \varepsilon)(\Omega^\text{tot}_m - 1) - 2\alpha (\ln(1 - \varepsilon) + 1)(\Omega^\text{tot}_m - 1)^2},
$$

11
If $\varepsilon > 0$, this expression is not singular at $\Omega_{m}^{\text{tot}} = 1$ provided that $f_{0}(\varepsilon) = 0$ that is to say

$$
\gamma_{-\infty} = \frac{\ln \left( \frac{\sqrt{25 - 24\varepsilon} - 1}{4} \right)}{\ln(1 - \varepsilon)}.
$$

Expanding this expression in series near $\varepsilon = 0$ leads to

$$
\gamma_{-\infty} \equiv \gamma^{\varepsilon}(\Omega_{m}^{\text{tot}} \to 1) = \frac{3}{5} + \frac{3}{125} \varepsilon + \frac{97}{6250} \varepsilon^{2} + \frac{737}{62500} \varepsilon^{3} + O(\varepsilon^{4})
$$

(66)

We recover the first two terms, the root of $\tilde{F}(1 - \varepsilon; \gamma)$ up to first order in $\varepsilon$ [5] mentioned above, Eq. (38). Let us remark that near $\Omega_{m}^{\text{tot}} = 1$, the derivative is given, up to terms of order $O(\varepsilon)$

$$
\frac{d\gamma}{d\Omega_{m}^{\text{tot}}} \simeq \frac{(5\gamma_{-\infty} - 3)\varepsilon}{2\alpha(1 - \Omega_{m}^{\text{tot}}) \ln((1 - \varepsilon)\Omega_{m}^{\text{tot}})} - \frac{\alpha(2\gamma_{-\infty} - 1) + 3 - 5\gamma_{-\infty}}{2\alpha \ln((1 - \varepsilon)\Omega_{m}^{\text{tot}})}
$$

(67)

For $\varepsilon > 0$, this expression is not singular at $\Omega_{m}^{\text{tot}} = 1$ provided that the first term is null, i.e. $\gamma_{-\infty} = \frac{3}{5} + O(\varepsilon)$, whereas for $\varepsilon = 0$, the first term is identically zero and the condition for the derivative to be non singular at $\Omega_{m}^{\text{tot}} = 1$ is $\gamma_{-\infty} = (\alpha - 3)/(2\alpha - 5)$ as obtained in [51].

We can proceed to the identification

$$
\gamma_{\Omega} = \frac{f_{1}(\varepsilon)}{-2\alpha \ln(1 - \varepsilon)}
$$

(68)

$$
\gamma_{\Omega \Omega} = \frac{f_{2}(\varepsilon)}{-2\alpha \ln(1 - \varepsilon)} - \frac{f_{1}(\varepsilon)(-2\alpha(\ln(1 - \varepsilon) + 1))}{(-2\alpha \ln(1 - \varepsilon))^{2}}
$$

(69)

We first solve for $\gamma_{\Omega}$, using (62)

$$
\gamma_{\Omega} = \frac{(1 - \varepsilon)\gamma_{-\infty}(2\gamma_{-\infty}(1 - \varepsilon)\gamma_{-\infty} + 3(\gamma_{-\infty} - 1)(1 - \varepsilon)^{1 - \gamma_{-\infty}} - \alpha(2\gamma_{-\infty} - 1))}{\ln(1 - \varepsilon)(3\varepsilon - 2(1 - \varepsilon)2\gamma_{-\infty} + 2\alpha(1 - \varepsilon)\gamma_{-\infty} - 3)}
$$

(70)

expanding in series of $\varepsilon$ gives

$$
\gamma_{\Omega} = \frac{\alpha}{5(2\alpha - 5)\varepsilon} - \frac{26\alpha^{2} - 5\alpha + 150}{250(2\alpha - 5)^{2}}
$$

(71)

Finally, we use this expression in $f_{2}$ (see Eq. [63]) in order to solve for $\gamma_{\Omega \Omega}$ and we obtain the following expansion (the close form expression is too complicated to be of interest)

$$
\gamma_{\Omega \Omega} = \frac{2\alpha}{5(2\alpha - 5)\varepsilon^{2}} - \frac{\alpha(504\alpha^{2} - 1525\alpha + 1250)}{125(2\alpha - 5)^{2}(4\alpha - 5)\varepsilon}
$$

$$
+ \frac{61696\alpha^{5} - 141960\alpha^{4} + 658150\alpha^{3} - 2382375\alpha^{2} + 3413125\alpha - 1818750}{18750(2\alpha - 5)^{3}(4\alpha - 5)^{2}}
$$

(72)
Figure 2: Left panel: The blue curve shows the reconstruction of $\gamma(\Omega_{m}^{\text{tot}}, \varepsilon)$ for $\varepsilon = 0.15$. The red curve is the second order approximation given by (57). We see that they match nicely for $\Omega_{m}^{\text{tot}} \simeq 1$. Right panel shows a zoom for $\Omega_{m}^{\text{tot}} \simeq 1$.

For $\alpha = -3$ ($w_{DE} = -1$) this gives

$$\gamma\Omega = \frac{3}{55\varepsilon} - \frac{399}{30250} - \frac{10161\varepsilon}{16637500} + \frac{12960073}{1202059375},$$

$$\gamma\Omega\Omega = \frac{6}{55\varepsilon^2} - \frac{31083}{257125\varepsilon} + \frac{12960073}{1202059375} (\Omega_{m}^{\text{tot}} - 1)^2 + ...$$

(73)

These results are illustrated with Figure (2) where we can see that the approximation (57) gives an excellent match to the solution $\gamma^{\varepsilon}(\Omega_{m}^{\text{tot}})$ for $\varepsilon = 0.15$, $\Omega_{m}^{\text{tot}} \simeq 1$. Note that we have obtained a double expansion with respect to both $\Omega_{m}^{\text{tot}}$ and $\varepsilon$ (neglecting all terms $O(\varepsilon)$)

$$\gamma^{\varepsilon}(\Omega_{m}^{\text{tot}}) \simeq \frac{3}{5} + \left[ \frac{3}{55\varepsilon} - \frac{399}{30250} \right] (\Omega_{m}^{\text{tot}} - 1)$$

$$+ \frac{1}{2} \left[ \frac{6}{55\varepsilon^2} - \frac{31083}{257125\varepsilon} + \frac{12960073}{1202059375} \right] (\Omega_{m}^{\text{tot}} - 1)^2 + ...$$

(75)

This suggests that, as a function of $\varepsilon$, $\gamma^{\varepsilon}$ has an essential singularity (i.e. a pole of infinite order) at $\varepsilon = 0$.

We will see now other situations were the value $\frac{3}{5}$ appears. Until now we were interested in an unclustered component which behaves like dust, hence $\varepsilon = \text{constant}$. For such a system we see from (75) that $\gamma^{\varepsilon}(\Omega_{m}^{\text{tot}} \to 1) \to \frac{3}{5}$. The same limit is obtained if the unclustered component instead of behaving like dust tends to such a behaviour in the past, in other words if it is a tracking component in the past with $\varepsilon$ tending to some constant value. Finally we note that our results hold for $\varepsilon < 0$, see e.g. [18].

It is also interesting to consider an unclustered component with $w_{DE} < w_{\text{uncl}} < 0$. Specializing to $w_{DE} = -1$, taking only the leading order term in $\varepsilon$ at each order of the expansion (75),
we obtain
\[
\gamma(\Omega_{DE}) = \frac{3}{5} + \frac{3}{55} \Omega_{DE} + \frac{3}{55} \left( \frac{\Omega_{DE}}{\varepsilon} \right)^2 + \frac{3}{55} \left( \frac{\Omega_{DE}}{\varepsilon} \right)^3 + \cdots
\]  
(76)
\[
= \frac{3}{5} \left[ 1 + \frac{1}{11} \sum_{k=1}^{\infty} \left( \frac{\Omega_{DE}}{\varepsilon} \right)^k \right] + \cdots
\]  
(77)
\[
= \frac{3}{5} \left[ 1 + \frac{1}{11} \left( -1 + \sum_{k=0}^{\infty} \left( \frac{\Omega_{DE}}{\varepsilon} \right)^k \right) \right] + \cdots
\]  
(78)
\[
= \frac{6}{11} + \frac{3}{55} \sum_{k=0}^{\infty} \left( \frac{\Omega_{DE}}{\varepsilon} \right)^k + \cdots
\]  
(79)

For our system, \( \frac{\Omega_{DE}}{\varepsilon} \to 0 \) so the sum is well-defined and yields
\[
\gamma(\Omega_{DE}) = \frac{6}{11} + \frac{3}{55} \frac{1}{1 - \frac{\Omega_{DE}}{\varepsilon}} + \cdots
\]  
(80)

For \( \frac{\Omega_{DE}}{\varepsilon} \to 0 \) we obtain again
\[
\gamma(\Omega_{DE} \to 0) \to \frac{6}{11} + \frac{3}{55} = \frac{3}{5}.
\]  
(81)

5 Summary and conclusion

The growth index \( \gamma \) is a interesting tool for the study of the evolution of matter perturbations on cosmic scales in various cosmological models (see e.g. [19] for its use in different contexts). Though it was introduced in order to characterize the influence of a non-vanishing spatial curvature on the growth of matter perturbations, interest for its study was revived in the context of DE models. Indeed, the growth index is a particularly efficient tool for the assessment of DE models in modified gravity.

We are interested in the global dynamics of \( \gamma \) from the asymptotic past to the asymptotic future. Though only a restricted interval of redshifts is relevant for observations, a global analysis yields a deeper insight [11]. Using the dynamical system approach we have found all critical points of the system. That unique trajectory for which the growth index remains finite from the asymptotic future to the asymptotic past is identified as the heteroclinic orbit connecting the critical points \((\Omega_m = 0, \gamma_{\infty})\) in the asymptotic future and \((\Omega_m = 1, \gamma_{-\infty})\) in the asymptotic past. The critical point \((\Omega_m = 0, \gamma_{\infty})\) is an attractor while the critical point \((\Omega_m = 1, \gamma_{-\infty})\) is a saddle point. These results confirm our earlier findings [11]. We recall that this unique trajectory corresponds to a vanishing decaying mode. As an additional result, we have refined our earlier results regarding the behaviour of \( \gamma(\Omega_m) \) in the DGP model and we find its very tiny decrease in the past, while it is essentially an increasing function except in the asymptotic future \((\Omega_m \lesssim 10^{-3})\).

We have considered a system consisting of DE with an effective equation of state having arbitrary dependence on redshift and partially clustered dust-like matter with some (small)
component of the latter remaining smooth at all scales, and investigated the growth of perturbations in it at scales exceeding the Jeans (or free streaming) length of gravitationally clustering matter (but much less than the Hubble scale). We have shown both analytically and numerically that $\gamma_{-\infty}^\varepsilon$ is the root of $\tilde{F}(1 - \varepsilon; \gamma)$ for $\Omega_m \to 1 - \varepsilon < 1$. Interestingly $\gamma_{-\infty}^\varepsilon$ does not depend on $w_{DE}$ which is possible because, as we have shown $\lim_{\varepsilon \to 0} \gamma_{-\infty}^\varepsilon \neq \gamma_{-\infty}$ where the last quantity corresponds to (usual) clustered dust and depends of course on $w_{DE}$. The quantity $\gamma_{-\infty}^\varepsilon$ was found earlier to correspond to the constant growth index corresponding to tracking DE in the matter era with $\Omega_{DE} \to \varepsilon$. We find further that $\frac{d\gamma_{-\infty}^\varepsilon}{d\Omega_m} \sim \frac{1}{\varepsilon^2}$ for $\varepsilon \simeq 0$ suggesting that $\gamma_{-\infty}^\varepsilon$ has an essential singularity at $\varepsilon = 0$. The results presented in this work show that besides its use for the assessment of DE models, the growth index $\gamma$ has also interesting mathematical properties reflecting physical properties of the underlying cosmological model.
