Abstract
In this paper we will consider quantum aspects of a non-local, infinite-derivative scalar field theory—a toy model depiction of a covariant infinite-derivative, non-local extension of Einstein’s general relativity which has previously been shown to be free from ghosts around the Minkowski background. The graviton propagator in this theory gets an exponential suppression making it asymptotically free, thus providing strong prospects of resolving various classical and quantum divergences. In particular, we will find that at one loop, the two-point function is still divergent, but once this amplitude is renormalized by adding appropriate counter terms, the ultraviolet behavior of all other one-loop diagrams as well as the two-loop, two-point function remains well under control. We will go on to discuss how one may be able to generalize our computations and arguments to arbitrary loops.

Keywords: quantum gravity, renormalization, non-local

1. Introduction

Formulating a quantum theory of gravity \cite{1–3} remains one of the most outstanding challenges of high energy physics. While string theory (ST) \cite{4} remains the most popular candidate, other notable efforts include loop quantum gravity (LQG) \cite{5, 6}, Causal set approach \cite{7}, and ideas based on asymptotic safety \cite{8}. An interesting recurrent feature that appears in
several of these approaches is non-locality. For instance, the entire formulation of LQG is based on non-local objects, such as Wilson loops and fluxes coming from the gravitational field. Strings and branes of ST are, by their very definition, non-local objects. Even classically they do not interact with each other at a specific spatial point, but rather over a region in space. Not surprisingly, non-local structures are a common theme in stringy field theory (SFT) models. For instance, these appear in noncommutative geometry [9] and SFT [10] (for a review, see [11]), and various toy models of SFT such as $p$-adic strings [12], zeta strings [13], and strings quantized on a random lattice [14, 15]. A key feature of these models is the presence of an infinite series of higher-derivative terms incorporating the non-locality in the form of an exponential kinetic correction. Finally, it is also intriguing to note that similar infinite-derivative modifications have also been argued to arise in the asymptotic safety approach to quantum gravity [16].

Accordingly, in [17–19] attempts were made to construct ghost-free, infinite-derivative theories of gravity which may be able to resolve space-time singularities such as the ones present inside the black holes and at the big bang. For instance, in [19] a non-singular bouncing cosmological background was obtained within a class of infinite-derivative gravity theories, around which the sub and super-Hubble perturbations are well behaved and do not show instabilities [20–22]. In fact, such an action can also modify the famous Raychaudhuri’s equation and alter the Hawking–Penrose singularity theorem [23], which can yield a non-singular bouncing cosmology without violating the null energy conditions.

It was not until recently though, that concrete criteria for any covariant gravitational theory (including infinite-derivative theories) to be free from ghosts and tachyons around the Minkowski vacuum was obtained by Biswas, Gerwick, Koivisto and Mazumdar (BGKM) [24, 25]; see [26] for a detailed exposition of the problem of instabilities in infinite-derivative theories. In [24], it was also shown how one can construct infinite-derivative theories of gravity where no new perturbative states are introduced and only the graviton propagator is modified by a multiplicative entire function. In particular, one can choose the entire function to correspond to the gaussian which suppresses the ultraviolet (UV) modes making the theory asymptotically free. For brevity we will refer to this case as the BGKM model.

Given the prospects of the BGKM model at resolving the classical singularities of GR, see [27] for an overview, here we are going to explore the possibility of formulating a quantum theory of BGKM, and the various challenges we need to overcome. For important works on slightly different approaches to quantizing gravity involving infinite-derivative interactions, see [28–32]. It is probably worth mentioning that in recent years there has been a growing interest in infinite-derivative gravitational theories in not only addressing the big bang singularity problem [19–22, 34] but also finding other cosmological applications [33].

Let us start by recalling the canonical examples of infinite-derivative actions that appear in string literature. These can all be written as

\[ \mathcal{L} = \sum_{n=0}^{\infty} \frac{1}{n!} \frac{1}{n^{\alpha}} \int d^4 x \mathcal{R}^n - \frac{1}{6} \sum_{n=1}^{\infty} \frac{1}{n!} \frac{1}{n^{\beta}} \int d^4 x \mathcal{R}^n \]

**4** Regarding the differences between the 'BGKM' model and [28, 29], uses propagators that go as $k^{-2\gamma - 4}$, $\gamma \geq 2$, in the UV while our propagator falls off exponentially (the exponential fall-off in the propagator is also seen as a special case in [29] and in [35]). In particular, this changes the degree of divergence, which, in our case, is a modified one counting not powers of momenta but exponents, and the divergence structure. Furthermore, we had to develop new techniques for regulating and evaluating the Feynman integrals. Also, the loop integrals are computed explicitly in our work. The 'BGKM' model has also been shown to address cosmological and black-hole singularities, as [34, 35] also do. Hence, we decided to give these theories a different name to distinguish them from other non-local/infinite-derivative models in vogue.
Here and hereafter, we are going to use the interplay between propagators and vertices is not unique to in any theories, but unfortunately the massive state has the peculiar property of making the classical theory unstable, and the theory contains ghosts. Once interactions are included, it makes the classical theory unstable, and the theory contains ghosts and is non-unitary. In contrast, the BGKM model provides gravitational analogues of equation (2.8) where the graviton propagator obtains an additional exponential suppression just as the scalar models.

So, can this exponential infinite-derivative modification also solve the quantum UV problem of gravity by making all the Feynman loops finite? The answer is not straightforward and our paper is essentially an effort to address this question. The main problem with the gravitational theories, as opposed to a scalar field theory, is that it is a gauge theory. And, one of the key features of gauge theories is that its free kinetic action is related to the interaction terms via the gauge symmetry. We will see that the exponential suppressions in propagators inevitably give rise to exponential enhancements in the vertex factors. Actually, this compensating interplay between propagators and vertices is not unique to infinite derivative theories, but any covariant theory of gravity, including Einstein’s theory and Stelle’s 4th order gravity [44], see also [45, 46]. In particular, the compensation between propagators and vertices is exact at the one-loop level making these contributions divergent as in GR. However, for higher loops, the superficial degree of divergence calculations is different from GR, because the counting is based on the number of derivatives.
on the pre-factors of the exponents rather than the degree of polynomial divergence; exponentials dominate any polynomial growth in the UV. In fact, a naive superficial divergence counting does suggest that diagrams with more than one loop should be finite [28, 29].

The principal aim of this paper is to investigate the validity of such divergence counting in some details in a simplified toy model which retains the compensating feature of exponential suppression and enhancements between the propagator and interaction respectively. We will consider a scalar field action, which maintains a combination of global scaling and shift symmetries, similar to the residual symmetry of gravity around the Minkowski background. Although this symmetry manifests itself only at the level of classical equations of motion, it will allow us to incorporate the compensating feature of exponential suppression and enhancement in propagators and interactions, respectively, that is present in the full gravitational theory. We found that one nice way to introduce this opposing effect in scalar models is to invoke the scaling symmetry. This is not central to our discussion, but rather than invoking an action in a completely ad hoc fashion, we felt that this gives us a slightly better motivation.

We will consider a cubic interaction that respects the symmetry and study two- and higher-point functions at one- and two-loops. We will first look at the vanishing external momentum limit, as they are technically easier to analyse and can already tell us whether a graph will be finite or not. It should be emphasized that we had to develop new techniques for regulating and evaluating the Feynman integrals. We will next look at the finite external momentum case, which is important in determining whether renormalizability arguments can be recursively pursued or not. Although, the cubic scalar interaction inherits a bad IR behavior—being unbounded from below—still it serves as a very good example to study the UV aspects of the theory, which is the main focus of our paper. In particular, we will employ both hard cutoff and dimensional regularization techniques to regulate the loop integrals, and we will speculate how higher loops in these theories may also remain finite in the UV.

The paper is organized as follows: in the following section 2, we introduce our toy quantum gravity model and discuss the expected UV behavior based on a naive superficial degree of divergence. In section 3, we will look at one- and two-loop quantum integrals at zero external momenta to assess whether the divergence structure confirms to the superficial degree of divergence. In section 4, we will look at one- and two-loop integrals with non-zero external momenta to identify both the divergent structure as well as the large (external) momentum behavior which is crucial in determining whether the theory can be renormalized loop-by-loop. In section 5, we will discuss the challenges in the renormalization prescription in the exponential infinite-derivative model, and demonstrate how this could be naturally addressed when one starts to use the dressed propagator instead of the bare propagator. In section 6, we will conclude by summarizing our results.

2. Quantum gravity toy model

2.1. Superficial degree of divergence

Throughout this paper we will be interested in metric fluctuations, \( h_{\mu\nu} \), around the Minkowski background:

\[
g_{\mu\nu} = \eta_{\mu\nu} + h_{\mu\nu}. \tag{2.1}
\]

Gravity being a gauge theory only contains kinetic terms, i.e. terms containing derivatives. In the case of GR all the terms contain two derivatives. In momentum space this means that the propagators behave as \( k^{-2} \), while each vertex also comes with a \( k^2 \) factor. This is the compensating feature discussed in the introduction and is a hallmark of gauge theories. Further in
four-dimensions, each momentum loop provides a $k^4$ factor in a quantum loop integral. The superficial degree of divergence of a Feynman diagram in GR is therefore given by (see [3, 44]):

$$D = 4L - 2I + 2V,$$

(2.2)

where $L$ is the number of loops, $V$ is the number of vertices, and $I$ is the number of internal propagators. Using the topological relation:

$$L = 1 + I - V,$$

(2.3)

we get

$$D = 2L + 2.$$

(2.4)

Thus, the superficial degree of divergence increases as the number of loops increases, which is why GR is said to be non-renormalizable.

For Stelle’s 4th-order theory [44], the graviton propagator goes as $\sim k^{-4}$, while the vertices $\sim k^4$, leading to a constant degree of divergence formula

$$D = 4.$$  

(2.5)

In other words, the degree of divergence does not increase with loops which enabled Stelle to prove that such a theory is renormalizable. Unfortunately, such a theory also contains a Weyl ghost which makes the theory non-unitary. As explained before, we will follow a different approach where we will introduce an infinite series of higher-derivative operators in a way that does not introduce any new states, ghosts or otherwise. We will see that the divergence counting will also be different as it will be based on the exponents rather than the degree of the polynomial momentum dependences.

### 2.2. Infinite-derivative gravitational action

The ‘simplest’ infinite-derivative action that can modify the propagator of the graviton without introducing any new states is of the form [24, 25]

$$S = S_{\text{EH}} + S_Q,$$

(2.6)

where $S_{\text{EH}}$ is the Einstein–Hilbert action

$$\int d^4x \sqrt{-g} \frac{R}{2},$$

(2.7)

and $S_Q$ is given by

$$S_Q = \int d^4x \sqrt{-g} \left[ R \mathcal{F}_1(\Box)R + R_{\mu\nu} \mathcal{F}_2(\Box)R^{\mu\nu} + R_{\mu\nu\lambda\sigma} \mathcal{F}_3(\Box)R^{\mu\nu\lambda\sigma}\right],$$

(2.8)

where the $\mathcal{F}_i$’s are analytic functions of $\Box$ (the covariant d’Alembertian operator):

$$\mathcal{F}_i(\Box) = \sum_n 0^i f_n \Box^n,$$

(2.9)

satisfying

$$2\mathcal{F}_1 + \mathcal{F}_2 + 2\mathcal{F}_3 = 0$$

(2.10)

---

6 Around Minkowski space or in any maximally symmetric background it can be shown that $\mathcal{F}_3$ is redundant, see [24, 25].

7 For other forms of infinite-derivative gravity theories which contain an additional scalar degree of freedom, see [25, 27].
and the constraint that the combination
\[ a(\Box) = 1 - \frac{1}{2} \mathcal{F}_2(\Box) - 2 \mathcal{F}_3(\Box) \]  \hspace{1cm} (2.11)
is an entire function, with no zeroes. In equation (2.9), the \( f_i \)'s are real coefficients. Equations (2.6)--(2.11) define the BGKM gravity models. The classical equations of motion have been studied for the above action [47], and shown to be free from black-hole type of singularities for ‘small’ central masses. In this paper therefore, we take the next logical step of investigating the quantum UV behavior of these theories.

For BGKM-type models, the quadratic (in \( h_{\mu\nu} \)) or ‘free’ part of the action simplifies considerably, and one obtains\(^8\):
\[ S_{\text{free}} = \frac{M_p^2}{2} \int d^4x \; h^{\perp\mu\nu} \Box a(\Box) h^{\perp\mu\nu}, \] \hspace{1cm} (2.12)
where \( h^{\perp\mu\nu} \) is the transverse traceless spin 2 graviton mode, satisfying:
\[ \nabla^\mu h^{\perp\mu\nu} = g^{\mu\nu} h^{\perp\mu\nu} = 0. \] \hspace{1cm} (2.13)
This leads to the propagator [24, 25],
\[ \Pi(k^2) = -\frac{i}{k^2 a(-k^2)} \left( \mathcal{P}^2 - \frac{1}{2} \mathcal{P}_0^2 \right) = \frac{1}{a(-k^2)} \Pi_{GR}, \] \hspace{1cm} (2.14)
for the physical degrees of freedom for the graviton (see [25, 48] for the definitions of the spin projector operators \( \mathcal{P}^2 \) and \( \mathcal{P}_0^2 \)).

Ideally, we should now compute the interaction terms for our non-local gravity theory and then use it to compute the Feynman diagrams. This however turns out to be an extremely challenging task for several reasons: Gravitational theories are all order theories and therefore contain interactions of all orders in \( h_{\mu\nu} \), and computing all these interactions is well beyond the scope of the current paper. While one can argue that all the terms which are higher order in fields have additional Planck suppressions\(^9\), and that therefore the most relevant piece in the low energy approximation comes from the cubic terms, unfortunately even computing the complete cubic interactions for an action such as equation (2.8) is challenging. Moreover, the expressions are rather complicated making further progress in evaluating Feynman diagrams very difficult.

Therefore, rather than taking on this arduous task, in this paper we wish to understand whether non-localization can at all help to tame the UV divergences in gravity theories, given the compensating nature of the exponential suppressions and enhancements present in the propagators and vertices. To avoid getting muddled in complex algebra we will try to understand the physics in a simple scalar toy model which we will arrive at using symmetry principles that helps us to retain some of the crucial properties of the full gravitational theories, see appendix A for details. For a comparative study and future reference we have

---

\(^8\) There is also a part of action for one of the scalar modes of the metric, but this is a ghost degree of freedom that is precisely required to cancel the time-like contributions of the spin-two field [48].

\(^9\) The easiest way to see this is to redefine \( h^{\perp}_{\mu\nu} \to M_p h^{\perp}_{\mu\nu} \), which is anyway required to make the free terms, equation (2.18), canonical. Then, each additional field comes with an additional Planck suppressed factor making them sub-leading to the cubic interactions in the low energy limit.
However, included some details about the gravitational action in appendix B, where we have calculated some of the prototype cubic interaction terms that one obtains from equation (2.6).

2.3. Motivating scalar toy model of quantum gravity from symmetries

It is well known that the field equations of GR exhibit a global scaling symmetry

$$g_{\mu\nu} \rightarrow \lambda g_{\mu\nu}. \quad (2.15)$$

When we expand the metric around the Minkowski vacuum, equation (2.1), the scaling symmetry translates to a symmetry for $h_{\mu\nu}$, whose infinitesimal version is given by

$$h_{\mu\nu} \rightarrow (1 + \epsilon)h_{\mu\nu} + \epsilon h_{\mu\nu}. \quad (2.16)$$

While we do not expect the scaling symmetry to be an unbroken fundamental symmetry of nature, the symmetry serves a rather useful purpose for us. It relates the free and interaction terms just like gauge symmetry does. Thus, we are going to use this combination of shift and scaling symmetry

$$\phi \rightarrow (1 + \epsilon)\phi + \epsilon, \quad (2.17)$$

to arrive at a scalar toy model whose propagator and vertices preserve the compensating nature found in the full BGKM gravity. Inspired by the discussion in the previous section, we will now consider a scalar toy model with a string field theory type free action:

$$S_{\text{free}} = \frac{1}{2} \int d^4x (\phi \Box a(\Box) \phi), \quad (2.18)$$

where for the purpose of this paper, we are going to choose [24, 25]:

$$a(\Box) = e^{-\Box/M^2}, \quad (2.19)$$

where $M$ is the mass scale at which the non-local modifications become important. In general, one is free to choose any entire function, while keeping in mind that $a(k^2) \rightarrow 1$ for the IR momentum, $k \rightarrow 0$, in order to recover the propagator of the usual GR. Note that the sign of $a(\Box)$ is also crucial in order to recover the correct Newtonian potential as shown in [24, 25].

The symmetry, equation (2.17), then uniquely fixes the cubic interaction term, see appendix C.

10 One way to obtain a toy scalar field model which mimics the gravitational Lagrangian is to substitute a conformally flat metric $h_{\mu\nu} = \Omega^2(x) g_{\mu\nu}$ in (2.8). The scalar field action that can be obtained this way is similar to the toy model we will consider, but its kinetic term has the wrong sign because it basically corresponds to the unphysical ghost degree in $P^0$, and also contains additional terms involving double sums that again makes the model technically more challenging to deal with. We therefore adopt a cleaner strategy based on symmetries to obtain the scalar toy model.

11 If we had chosen $a(\Box)$ to be

$$a(\Box) = e^{\Box/M^2}, \quad (2.20)$$

where $M^2 > 0$, then we can perform the loop integrals for $a(\Box) = e^{\Box/M^2}$, assuming $M^2 > 0$, and then analytically continue to $M^2 < 0$. In this way the Newtonian potentials $\Phi(\epsilon)$ and $\Psi(\epsilon)$ would be given by

$$\Psi(\epsilon) = \Phi(\epsilon) = \frac{2\epsilon M^2}{M^2 \epsilon} \frac{\text{Erfi}(\frac{Mr}{2})}{\text{Erfi}(\frac{\epsilon}{i})}, \quad (2.21)$$

is the imaginary error function and admits real values for real $\epsilon$. Clearly in this case, the Newtonian potential is purely imaginary indicating an unphysical theory. See also [49] for a discussion of Newtonian singularities in higher-derivative gravity models.
\[
S_{\text{int}} = \frac{1}{M_p} \int d^4x \left( \frac{i}{4} \phi \partial_\mu \phi \partial^\mu \phi + \frac{i}{4} \phi \Box \phi + \frac{i}{4} \phi \partial_\mu \phi \alpha (\Box) \phi - \frac{i}{4} \phi \partial_\mu \phi \alpha (\Box) \partial^\mu \phi \right),
\]

(2.22)

up to integrations by parts. Our *toy model* action is then given by:

\[
S_{\text{scalar}} = S_{\text{free}} + S_{\text{int}}.
\]

(2.23)

It is now time to revisit the superficial degree of divergence for this *toy model*.

Since an exponential suppression always dominates over a polynomial growth, the naive expectation is that as long as the exponentials come with a negative power, the integrals should converge. Thus, rather than computing the power of polynomial divergence in momentum, we are really interested in calculating the pre-factor in the exponent, and this radically changes the counting of the superficial degree of divergence.

Since every propagator comes with an exponential suppression, see equation (2.18), while every vertex comes with an exponential enhancement, equation (2.22), the superficial degree of divergence counting in exponents is given by

\[
E = V - I.
\]

(2.24)

By using the topological relation, equation (2.3), we obtain:

\[
E = 1 - L.
\]

(2.25)

Thus, except for the \( L = 1 \) loop, \( E < 0 \), and the corresponding loop amplitudes are superficially convergent. In appendix A, we discuss the analogous calculation in the complete BRST-invariant quantum infinite-derivative gravitational action. The conclusion is exactly the same. The rest of the paper is devoted to investigating whether the naive expectation about the convergence properties of the Feynman diagrams hold up in explicit calculations involving quantum loop calculations.

3. Divergence structure with zero external momenta

3.1. Feynman rules

All the Feynman rules and Feynman integral computations in this paper are carried out in Euclidean space after analytic continuation \((k_0 \rightarrow ik_0 \text{ and } k^2 \rightarrow k^2_E \text{ using the mostly plus metric signature; we shall drop the } E \text{ subscript for notational simplicity})\). The final results we obtain can then be analytically continued back to Minkowski space as desired.

The Feynman rules for our action equations (2.18) and (2.22) can be derived rather straightforwardly. The propagator in momentum space is then given by

\[
\Pi(k^2) = \frac{-i}{k^2 e^{k^2}},
\]

(3.1)

where barred four-momentum vectors from now on will denote the momentum divided by the mass scale \( M \). The vertex factor for three incoming momenta \( k_1, k_2, k_3 \) satisfying the conservation law:

\[
k_1 + k_2 + k_3 = 0,
\]

(3.2)

is given by

\[
\frac{1}{M_p} V(k_1, k_2, k_3) = \frac{i}{M_p} C(k_1, k_2, k_3) \left[ 1 - e^{k_1^2} - e^{k_2^2} - e^{k_3^2} \right],
\]

(3.3)
Let us briefly explain how we obtain the vertex factor. The first term originates from the term, \( \frac{i}{2} \partial_\mu \phi \partial^\mu \phi \), which using equation (3.2) in the momentum space, reads

\[
- \frac{i}{2} (k_1 \cdot k_2 + k_2 \cdot k_3 + k_3 \cdot k_1) = \frac{i}{4} (k_1^2 + k_2^2 + k_3^2).
\]

The second term comes from the terms, \( \frac{i}{2} \partial_\mu \phi \partial^\mu \phi \), and \( - \frac{i}{2} \partial_\mu \phi \partial^\mu \phi \). In the momentum space, again using equation (3.2), we get

\[
\frac{i}{4} (k_3 \cdot k_1 + k_1 \cdot k_2 - k_2 \cdot k_3) = - \frac{i}{4} (k_1^2 + k_2^2 + k_3^2).
\]

The third and the fourth terms in equation (3.3) arise in an identical fashion.

For instance, choosing \( k_3 = 0 \), we obtain \( k_1 = -k_2 = k \), which then gives us

\[
V(k) \equiv V(k, -k, 0) = -ik^2 e^{i \xi^2}.
\]

We will also often encounter the square of the vertex factor, which is given by:

\[
V^2(k_1, k_2, k_3) = i^2 C^2(k_1, k_2, k_3) \left[ 1 - 2e^{i \xi^2} - 2e^{i \xi^2} + 2e^{i \xi^2} e^{i \xi^2} + 2e^{i \xi^2} e^{i \xi^2} + e^{2i \xi^2} + e^{2i \xi^2} \right].
\]

### 3.2. One-loop, two-point function with zero external momenta

Let us start with the one-loop two-point function. There is only one Feynman diagram as depicted in figure 1 (left). According to the Feynman rules, we have

\[
\Gamma_2 = \frac{i}{2M^2} \int \frac{d^4k}{(2\pi)^4} \frac{V^2(k)}{i^2k^4 e^{2i \xi^2}}.
\]

Note that we are working in an Euclidean space and that the symmetry factor is 2. The angular integrations can be performed trivially, see appendix D.1 for details, as the integrand only

\[ \text{is } (2\pi)^4. \]

\[ \text{is } i^2k^4 e^{2i \xi^2}. \]

\[ \text{is } V^2(k). \]

\[ \text{is } i^2k^4 e^{2i \xi^2}. \]
depends on the norm of the external momentum, leaving us with

$$\Gamma_2 = \frac{i}{2M_p^2} \frac{4\pi}{(2\pi)^2} \int_0^\Lambda \frac{dk}{2} \frac{\pi k^3}{2}. \quad (3.10)$$

Integrating with respect to \( k \) from 0 to \( \Lambda \), where \( \Lambda \) is a hard cutoff, we obtain:

$$\Gamma_2 = \frac{i\Lambda^4}{64M_p^2 \pi^2}. \quad (3.11)$$

We see that the integral goes like \( \int d^4k \), and is therefore sensitive to the UV cut-off. This result is in complete accordance with the analysis of superficial degree of divergence according to which at one-loop level the exponential non-locality does not affect the integrals. The divergence structure is exactly the same as that of GR at one-loop.

### 3.3. \( N \)-point function with zero external momenta

An interesting fact for gravitational theories is that the superficial degree of divergence does not depend on the number of external vertices. This is true both in GR, see equation (2.4), as well as in BGKM gravity and in infinite-derivative scalar field theory, see equation (2.25). Let us then calculate the \( N \)-point function at one loop, see figure 1 (right). As one can see, the \( N \)-point diagram is not particularly different from the two-point diagram; it is an \( N \)-polygon with \( N \) vertices and \( N \) edges. Thus, instead of a square of the propagator and vertex factor, one now has \( N \) powers of them:

$$\Gamma_N = \frac{i}{M_p^2} \int \frac{d^4k}{(2\pi)^4} \frac{V^N(k)}{i^N k^{2N} e^{2iN\phi}} = (-1)^N \frac{i\Lambda^4}{32M_p^2 \pi^2}, \quad (3.12)$$

where again \( \Lambda \) is the hard cutoff. As expected, its divergence is the same as that of the two-point function precisely as predicted by the divergence power-counting. The above diagrams are also known as ring diagrams, and they contribute to the effective potential. The symmetry factor\(^{13}\) is \( 2N \), and summing all the one-loop diagrams, one obtains the one-loop contribution to the effective potential

$$V_{\text{eff}}^{(1)}(\phi) = i \sum_{N=1}^\infty \Gamma_N \phi^N = \sum_{N=1}^\infty (-1)^{N+1} \frac{\Lambda^4}{2N} \frac{\Lambda^4}{32M_p^2 \pi^2} \phi^N = \frac{\Lambda^4}{64\pi^2} \ln \left( 1 + \frac{\phi}{M_p} \right). \quad (3.13)$$

as is typical, see also [41, 42, 50] for similar computations. In a theory of gravity, we of course, do not expect to find such an effective potential as that would violate general covariance, diagrams coming from different order interactions must cancel the contributions. We obtain these terms in our toy model since the scaling symmetry is only a symmetry of the field equations and not the entire action, and therefore it is expected to be broken at the quantum level.

The prescription that was used in [42] to eliminate these divergent terms while preserving the pole mass is to simply add an opposing counter term. This is also the prescription that is followed in standard field theoretic calculations (renormalization conditions), and we will adopt the same convention as we move on to higher loop diagrams.

Our calculations corroborated the expected divergence structure, equation (2.25), in infinite-derivative theories, or any covariant theory of gravity for that matter. To prove

\[^{13}\] It should be noted that the symmetry factor is equal to \( 2N \) when 1PI corrections to the effective potential are considered (the external points are not fixed in that case). When computing a Green’s function, the symmetry factor is equal to 2 for \( N = 1, 2 \) and to 1 for \( N > 2 \).
renormalizability, the real challenge will be to demonstrate that once these one-loop divergences (subdivergences) are eliminated by counterterms in higher loop subdiagrams, the remaining loop integrals yield finite result. At the least this means that the higher than one-loop diagrams cannot diverge more than the bare vertex. This is what we now want to check in the remaining sections.

3.4. Two-point function at two-loop order

3.4.1. General structure. We wish to now investigate the second feature of the divergence formula, equation (2.25), namely, that for higher than one-loop no new divergences should emerge. Since there are always subdivergent one-loop graphs within a two-loop diagram, we do not expect in general finite results, but what we wish to find here is that the two-loop graph should have the same divergence behavior as that of the one-loop counterpart. In other words, they should diverge at most as \( \Lambda^4 \). This result will be in contrast with the GR case, where the two-loop diagrams diverge as \( \Lambda^6 \).

There are two Feynman diagrams as depicted in figure 2. The Feynman diagram with zero external momenta in figure 2 (left) is given by

\[
\Gamma_{2,2a} = \frac{i^2}{2\pi^3 M_p^4} \int \frac{d^4k_1}{(2\pi)^4} \frac{d^4k_2}{(2\pi)^4} \frac{V(k_1) V(k_2) V^2(k_3)^2 k_3^2 k_3^4 e^{2i\lambda_1} e^{2i\lambda_2}}{k_1^2 k_2^2 k_3^4}.
\]

(3.14)

where \( k_3 = -k_1 - k_2 \), and the expression is symmetric in \( k_1 \) and \( k_2 \). The numerator contains a sum of different exponents, so that the overall integral can be written in the form

\[
\Gamma_{2,2a} = \frac{i}{2M_p^2} \int \frac{d^4k_1}{(2\pi)^4} \frac{d^4k_2}{(2\pi)^4} \frac{C^2}{k_1^2 k_2^2 k_3^3} \sum_i \lambda_i \exp\left[ E_i(k_1, k_2) \right].
\]

(3.15)

where \( E_i \)'s are quadratic polynomials of \( k_1 \), \( k_2 \) and \( \lambda_i \) are constants taking on the values \(-2, -1, +1, +2\). Firstly, let us note that one can always find linear combinations of \( k_1 \), \( k_2 \) and \( \lambda_i \) that make \( E_i \) is diagonal:

\[
E_i = a_1 q_1^2 + a_2 q_2^2.
\]

(3.16)

Now, depending upon the value of the \( a_i \)'s one can classify the terms in three groups:

(I) If both \( a_1 \), \( a_2 \) < 0, both the momentum integrals can be performed to provide a finite answer.

(II) If both \( a_i \)'s are nonzero, but one of them is positive, then one can obtain the integrals by suitably analytically continuing results from the \( a_i < 0 \) to \( a_i > 0 \) region.

(III) Finally, there are cases when one of the \( a_i \)'s is zero. We expect that this represents the divergent contribution from the one-loop subdiagram embedded within the two-loop graph. We shall check whether this provides a \( \Lambda^4 \) divergence, or a \( \Lambda^6 \) as in usual GR.
3.4.2. Convergent groups (I) terms. Let us first look at the group (I) terms. The overall exponential factors for the group (I) type terms are given by
\[ e^{-k_i^2} e^{-k_i^2}, \quad e^{-k_i^2} e^{-k_i^2}, \quad e^{-k_i^2} e^{-k_i^2}, \quad e^{-k_i^2} e^{-k_i^2}. \]  
(3.17)
The first integrand evaluates to
\[ \frac{3iM^6 \log \left( \frac{4}{3} \right)}{4096M_p^4 \pi^4}, \]
(3.18)
while all the other three gives us the same contribution:
\[ \frac{-iM^6 (3 + \log(4))}{2048M_p^4 \pi^4}. \]
(3.19)
Thus, all together we have
\[ \Gamma_{1,2} = \frac{3iM^6}{2048M_p^4 \pi^4} \left[ \frac{1}{2} \log \left( \frac{4}{3} \right) - (3 + \log 4) \right]. \]
(3.20)

3.4.3. Group (II) and (III) terms and the divergence structure. Next let us look at the integrals originating from the last three terms in equation (3.8). With overall exponents
\[ e^{k_i^2} e^{-k_i^2}, \quad e^{k_i^2} e^{-k_i^2} e^{-k_i^2}, \quad e^{k_i^2} e^{-k_i^2} e^{-k_i^2}, \quad e^{k_i^2} e^{-k_i^2} e^{-k_i^2}, \]
(3.21)
these form the group (II) set with one eigenvalue positive and one negative. These integrals can also be evaluated by employing suitable analytic continuation methods, please see appendix D.2 for details.
Again, all the terms contribute equally, and we get
\[ \Gamma_{1,2,1+} = \frac{3iM^4}{4096\pi^4 M_p^4} \left( M^2 \log(4) - 8 - 4 \Lambda^2 \right). \]
(3.22)

We are left to tackle the group (III) terms originating from the fifth, sixth and seventh terms in equation (3.8), whose exponential contributions coming from the vertices are given by
\[ e^{k_i^2} e^{2k_i^2} e^{k_i^2}, \quad e^{k_i^2} e^{2k_i^2} e^{k_i^2}, \quad e^{2k_i^2} e^{2k_i^2}. \]
(3.23)
Since the exponential contribution of the propagators is given by:
\[ e^{-2k_i^2} e^{-2k_i^2} e^{-k_i^2}, \]
(3.24)
the overall exponents, \( E_n \), for the three above cases are
\[ -\bar{k}_1^2, \quad -\bar{k}_2^2, \quad -\bar{k}_3^2. \]
(3.25)
Clearly, there is no exponential damping along the directions orthogonal to \( k_1, k_2 \) and \( k_3 \) respectively. Accordingly, while one of the momentum integrals is convergent due to the presence of the exponential, the other one can only be computed using a hard cutoff. The result is identical for all the three diagrams, and one obtains
\[ \Gamma_{2,111} = \frac{iM^2}{4096M_p^4 \pi^4} \left[ 2M^4 \left( 6 \log \left( \frac{\Lambda}{M} \right) + 5e^{-\frac{\omega}{\sqrt{M}}} - 3Ei \left( -\frac{\Lambda^2}{M^2} \right) + 3\gamma - 5 \right) \right. \\
+ \Lambda^2 M^2 \left( e^{-\frac{\omega}{\sqrt{M}}} + 15 \right) + \Lambda^4 \left( 6 - e^{-\frac{\omega}{\sqrt{M}}} \right) - \frac{N^2Ei \left( -\frac{\Lambda^2}{M^2} \right)}{M^2} \right], \quad (3.26) \]

where

\[ Ei(z) \equiv - \int_{-\infty}^{z} \frac{e^{-t}}{t} dt \]

is the exponential-integral function, see [51], and has a branch cut discontinuity in the complex \( z \)-plane running from 0 to \( \infty \). The sign \( \int \) indicates that the principal value of the integral is taken. We note that, for large negative \( z \), the \( Ei \) function falls off as a Gaussian and therefore can be ignored in the \( \Lambda \to \infty \) limit. Therefore, the surviving divergent pieces read

\[ \Gamma_{2,111} = \frac{iM^2}{4096M_p^4 \pi^4} \left[ 12M^4 \log \left( \frac{\Lambda}{M} \right) + 15\Lambda^2 M^2 + 6\Lambda^4 + 2M^4 (3\gamma - 5) \right]. \quad (3.28) \]

Firstly, we see that the divergence is indeed \( \propto \Lambda^4 \), as the superficial divergence argument suggested, and does not grow as \( \Lambda^6 \) that one would find in GR.

We note that all the results obtained in this section have been divided by a symmetry factor 2 for the diagram. Summing all the integrals, we obtain our final result:

\[ \Gamma_{2,2a} = \frac{iM^2}{4096M_p^4 \pi^4} \left[ M^4 \left( 12 \log \left( \frac{\Lambda}{M} \right) - 52 + 2(3\gamma - 5) - 3\log(3) \right) \right. \\
+ \left. 3\Lambda^2 M^2 + 6\Lambda^4 \right]. \quad (3.29) \]

To reiterate, \( \Gamma_{2,1} \sim \Gamma_{2,2} \sim \Lambda^4 \), as the counting of superficial degree of divergence would suggest. While we have not explicitly calculated higher than two loop graphs, we would expect the same pattern to continue to hold, i.e., we do not expect larger than quartic divergence in any loop order.

3.4.4. The other two-loop diagram. After setting the external momenta equal to zero, the Feynman diagram in figure 2 (right) becomes

\[ \Gamma_{2,2b} = \frac{i^2}{2^5M_p^4} \int \frac{d^4k_1}{(2\pi)^4} \frac{d^4k_2}{(2\pi)^4} \frac{V^2(k_1) V^2(k_2)}{k_1^2 \left( \frac{k_1}{2} + k_2 \right)^2 \left( \frac{k_1}{2} - k_2 \right)^2} e^{\mu_1^2 e_i \left( \frac{k_1}{2} + k_2 \right) \left( \frac{k_1}{2} - k_2 \right)}, \quad (3.30) \]

where we have assumed symmetrical routing of momenta and the symmetry factor of the diagram is 2. Again, the numerator contains a sum of different exponents, so that the overall integral can be written in the form

\[ \Gamma_{2,2b} = \frac{i}{2M_p^4} \int \frac{d^4k_1}{(2\pi)^4} \frac{d^4k_2}{(2\pi)^4} \frac{D^2}{k_1^2 \left( \frac{k_1}{2} + k_2 \right)^2 \left( \frac{k_1}{2} - k_2 \right)^2} \sum_i \mu_i \exp \left[ F_i(k_1, k_2) \right], \quad (3.31) \]

where \( F_i \)'s are quadratic polynomials of \( k_1, k_2 \), and \( \mu_i \) are constants which take on the values \( -2, -1, +1, +2 \), similar to the first two-loop diagram. Also
If we change variables $k_1 \to k'_1$, $-\frac{k_1}{2} - k_2 \to k'_2$ (or, equivalently, $k_1 \to k'_1$ and $-\frac{k_1}{2} + k_2 \to k'_2$) in $\Gamma_{2,1}$, we get $\Gamma_{2,2}$, since the Jacobian is 1; i.e., equation (3.31) is exactly equivalent to equation (3.15):

$$\Gamma_{2,2b} = \Gamma_{2,2a}.$$  

Hence, the results for both the two-loop diagrams are exactly the same. To reiterate, $\Gamma_{2,1} \sim \Gamma_{2,2} \sim \Lambda^3$, which would seem to corroborate the counting of a superficial degree of divergence (2.25).

4. External momentum dependence and renormalizability

4.1. Arbitrary loop diagrams

The calculations in the earlier subsection supported our naive divergence counting argument in section 2, which suggested that all one-loop diagrams should be divergent $\sim \Lambda^3$, and that this divergence should not increase as we go to higher loops. While this agreement is encouraging, just the fact that the divergence does not increase at higher loops does not guarantee renormalizability. To achieve renormalizability, one has to check, for instance, that once the one-loop sub-divergences are removed from a higher loop diagram, the diagram becomes finite. This requires keeping track of the UV behavior of the external momenta while performing the various loops. Let us illustrate the point with a few examples.

Consider the two-loop diagram in figure 2, left. This contains a sub-divergent three-point, one-loop diagram. If we had found a prescription to make the one-loop diagram finite (for instance by adding appropriate counter terms as suggested in the previous section\textsuperscript{14}), then the two-loop diagram should really be replaced by figure 3 (left), where we now have a finite renormalized three-point function. We then have to perform a loop integral involving the renormalized three-point function:

\textsuperscript{14} We will later see that the three-point function is actually finite once we introduce the dressed propagator.
where $k_3 = -k_1 - k_2$. The key question then is whether this latter integral is finite? A very similar reasoning can be applied to the two-loop diagram in figure 2 (right), where one can think of replacing the two-point one-loop subdiagram with the one-loop renormalized two-point function, see figure 3 (right), and then perform the remaining loop integral:

$$\Gamma_{2,3a} = \frac{i^2}{2\pi^3 M_p^2} \int \frac{d^4k_1}{(2\pi)^4} \frac{d^4k_2}{(2\pi)^4} \frac{V(k_1)V(k_2)V^2(k_1, k_2, k_3)}{k_1^4 k_2^4 e^{k_1^2 + 2k_1^2 + k_2^2} k_3^4 e^{2k_3^2}},$$

(4.1)

$$\Gamma_{2,3b} = \frac{i^2}{2\pi^3 M_p^2} \int \frac{d^4k_1}{(2\pi)^4} \frac{d^4k_2}{(2\pi)^4} \frac{V^2(k_1)V^2\left(k_1, -\frac{k_1}{2} + k_2, -\frac{k_1}{2} - k_2\right)}{k_1^4\left(\frac{k_1}{2} + k_2\right)^2\left(\frac{k_1}{2} - k_2\right)^2 e^{3k_1^2 + \left(\frac{3}{2} + k_3\right)^2 + \left(\frac{3}{2} - k_3\right)^2}},$$

(4.2)

$$\Gamma_{2,3b} = \frac{i^2}{2\pi^3 M_p^2} \int \frac{d^4k_1}{(2\pi)^4} \frac{V^2(k_1)\Gamma_{2,1r}(k_1, -k_1)}{k_1^6 e^{6k_1^2}}.$$

(4.3)

Actually, this is a very general prescription, any $n$-loop diagram can be thought of as a one-loop integral over a graph containing renormalized vertex corrections and dressed propagators, see figure 4 (right) for illustration. To prove renormalizability recursively the challenge then is to prove that if all loops up to $n - 1$ are finite, then the remaining one-loop integral remains finite too!

Now, we have already seen from counting arguments in the previous section that if the vertices and the propagators are enhanced and suppressed respectively by the same exponential factor then a one-loop diagram remains divergent. This argument can clearly be applied to $n$-loop graphs when viewed as one-loop diagrams involving renormalized vertices, and (most importantly) renormalized propagators. What the argument suggests is that to have a chance at renormalizability, the renormalized vertices must be growing less strongly than the renormalized or the ‘dressed’ propagators. In this section, we are going to compute
external momentum dependence of the two-point function at one-loop, and discuss its ramifications.

4.2. One-loop two-point function with arbitrary external momenta

Calculating the dressed propagator boils down to calculating the two-point function with external momenta. At the one-loop level with external momenta \( p, -p \) (we assume the convention that the external momenta are incoming and sum to zero), and symmetrical routing of momenta, the Feynman integral is given by (see appendix D.1 for details)

\[
\Gamma_{2,1}(p^2) = \frac{i}{2\pi^2 M_p^2} \int \frac{d^4 k}{(2\pi)^4} \frac{V^2 \left( -p, \frac{p}{2} + k, \frac{p}{2} - k \right)}{\left( \frac{p}{2} + k \right)^2 \left( \frac{p}{2} - k \right)^2 e^{\left( \frac{p}{2} + k \right)^2} e^{\left( \frac{p}{2} - k \right)^2}}, \tag{4.4}
\]

where

\[
V^2 \left( -p, \frac{p}{2} + k, \frac{p}{2} - k \right) = i^2 C^2 \left[ 1 - 2e^{\left( \frac{p}{2} + k \right)^2} - 2e^{\left( \frac{p}{2} - k \right)^2} - 2e^{\left( \frac{p}{2} + k \right)^2} e^{\left( \frac{p}{2} - k \right)^2} \right] + 2e^{\left( \frac{p}{2} - k \right)^2} e^{2\rho^2} + 2e^{\left( \frac{p}{2} + k \right)^2} e^{2\rho^2} + 2e^{\left( \frac{p}{2} - k \right)^2} e^{2\rho^2} + e^{2\rho^2} \tag{4.5}
\]

and

\[
C = \frac{1}{4} \left[ \frac{p^2}{\epsilon^2} + \left( \frac{p}{2} + k \right)^2 + \left( \frac{p}{2} - k \right)^2 \right]. \tag{4.6}
\]

While using a cut-off scheme to regulate the integral is more instructive to see the divergent structure, technically it is much more convenient to use dimensional regularization, which is what we will employ from here onwards. The integral in equation (4.4) contains several terms coming from the various sums of exponents that make up the vertex functions. The different integrals arising from the sum in \( V^2 \) can be grouped in three ways:

(I) When the integrand contains no exponentials, this comes from the fifth term in equation (4.5), and gives a divergent result.

(II) When we have a Gaussian damping term present in equation (4.5). This is the case for all the terms except the fifth, eighth and the ninth terms and gives a convergent answer.

(III) The eighth and the ninth terms contain a \( pk \) in the exponent of equation (4.5), and they are the most difficult to handle analytically, but they are not particularly important for our discussions as will become clear soon. Let us discuss these terms separately now.

4.2.1. Group (I) terms. The divergent integral corresponding to the fifth term can again be calculated straightforwardly using dimensional regularization (see appendix E), and one obtains

\[
\Gamma_{2,1,5}(p^2) = \frac{i p^4}{256 \pi^2 M_p^2} \left( \frac{2}{\epsilon} - \log \left( \frac{p^2}{4\pi M_p^2} \right) - \gamma + 2 \right). \tag{4.7}
\]

Let us make a couple of comments: Firstly, the \( p^2 \to 0 \) limit is well defined, i.e., none of the expressions diverge. If it did, that would make the low energy limit ill-defined, ruling out such modifications phenomenologically even as an effective theory. Secondly, the counter term needed to cancel the divergence is given by
\[ \mathcal{L}_{ct} = -\frac{1}{256\pi^2 M_p^2} \int d^4x \phi \Box^2 \phi, \quad (4.8) \]

or equivalently
\[ \Gamma_{2.1,ct}(p^2) = -\frac{i p^4}{128\pi^2 M_p^2} \epsilon. \quad (4.9) \]

The counter term is clearly not of the same form as the original action equation (2.23). This is not surprising given that the symmetry principle we used to write down the action equation (2.23) was not a symmetry of the action, but only that of the field equations.

4.2.2. Group (II) terms. The group (II) type integrals are all convergent due to the presence of the exponential damping factor. They can therefore be evaluated rather straightforwardly to yield
\[
\Gamma_{2.1,II}(p^2) = \frac{i M^4 e^{\rho^2}}{512 M_p^2 \pi^2 p^2} \left[ -2e^{\rho^2}(e^{2\rho^4} - 1)\rho^6 Ei(-\rho^2) \\
+ (e^{\rho^2} - 1)(-2(\rho^4 + 3\rho^2 + 2) \\
+ \left( \frac{\mu^2}{e^\mu} - \frac{\rho^2}{e^{\rho^2}} \right)(2\rho^4 + 5\rho^2 + 4) + e^{\rho^2}(e^{\rho^2} - 1)\rho^6 Ei\left(-\frac{\rho^2}{2}\right) \\
+ 2e^{\rho^2}(7(\rho^4 + \rho^2 + 2)) \right]. \quad (4.10)
\]

Again, the expression is regular as \( p^2 \to 0 \). This again shows that the theory has a well defined low energy limit. However, to assess the renormalizability of the theory we need to look at the UV behavior, and especially track any exponential growth. With this in mind let us look at the various terms that grow as a Gaussian as \( p^2 \to \infty \):
\[
\Gamma_{2.1,II}(p^2) = \frac{i M^4}{512 M_p^2 \pi^2 p^2} \left[ 3(1 - 2M^2 p^{-2} + 8M^4 p^{-4})e^{\mu^2} - 2e^{\rho^2} - e^{\rho^2} \right] + \ldots \quad (4.11)
\]

where the \ldots indicate subleading terms or terms which are growing at most as a polynomial, and we have used the relation
\[
\lim_{x \to +\infty} x^2 e^{\alpha x^2} Ei(-\alpha x^2) = -\frac{1}{\alpha}, \quad (4.12)
\]

for positive \( \alpha \) to obtain the asymptotic behavior. In particular, as \( p^2 \to \infty \), we find
\[
\Gamma_{2.1,II}(p^2) \to \frac{i M^4 e^{\mu^2}}{512 M_p^2 \pi^2} \left[ 9 - 12\rho^2 + \ldots \right]. \quad (4.13)
\]

As we see, the correction to the propagator grows with a larger exponent than the ‘bare’ inverse propagator, and this will be crucial in proving finiteness of the one-loop diagrams and our arguments on renormalizability of the theory.
4.2.3. Group (III) terms. For the purpose of completeness, let us also compute the group (3)
integrals using dimensional regularization (see appendix E for details). We find that the $e^{p_k}$
integrals do not give rise to any poles. There is no simple analytical result for the integral, but it
can be expressed as a single integral:
$$
\Gamma_{2,1,iii}(\vec{p}^2) = \frac{iM^4}{128\pi M_p^2} \int_0^1 \mathrm{d}r \, e^{(1-2r)p^2} \left[ t(r, \vec{p}) Y_0 \left( 2\sqrt{r - r^2} \vec{p}^2 \right) + u(r, \vec{p}) \sqrt{r - r^2} Y_1 \left( 2\sqrt{r - r^2} \vec{p}^2 \right) \right],
$$
(4.14)
where
$$
t(r, \vec{p}) = -16\vec{p}^4 r^4 + \left( 32\vec{p}^4 + 8\vec{p}^2 \right) r^3 - \left( 26\vec{p}^4 + 12\vec{p}^2 \right) r^2 + \left( 10\vec{p}^4 + 4\vec{p}^2 \right) r - 2\vec{p}^4,
$$
(4.15)
$$
u(r, \vec{p}) = -16\vec{p}^4 r^3 + \left( 24\vec{p}^4 + 4\vec{p}^2 \right) r^2 - \left( 16\vec{p}^4 + 4\vec{p}^2 - 8 \right) r + 4\vec{p}^4 + 3\vec{p}^2 - 4,
$$
(4.16)
and $Y_\nu(z)$ is the Bessel function of the second kind and $Y_\nu(z) \to 0$ as $z \to \infty$. The above
equation (4.14) is regular as $\vec{p} \to \infty$. In figure 5 (left), we have plotted the ratio
$\Gamma_{2,1,iii}(\vec{p}^2)/\Gamma_{2,1,io}(\vec{p}^2)$ as a function of $\vec{p}$. As we can see, the $\Gamma_{2,1,io}(\vec{p}^2)$ term
dominates for large momentum, and is therefore going to be the most important for understanding the UV
behavior of the quantum theory.

To summarize, from our preceding calculations in the UV limit we have:
$$
\Gamma_{2,1}(p^2) = \Gamma_{2,1,io}(p^2) + \Gamma_{2,1,io}(p^2) + \Gamma_{2,1,iii}(p^2) \approx \frac{9iM^4 e^{3p^2/2}}{512M_p^2 \pi^2}.
$$
(4.17)

---

Note: We used the relation, $J_\nu(z) = \frac{e^{i\nu}}{\pi} \Psi_\nu(\nu + 1; -\frac{i}{2}e^2)$, between the Bessel function of the first kind and the
regularized confluent hypergeometric function. Moreover, the Cauchy principal value (CPV) prescription was used to
compute some of the irregular integrals.

---

**Figure 5.** Left: a log-linear plot of $A(\vec{p}^2) = \frac{\Gamma_{2,1,io}(\vec{p}^2)}{\Gamma_{2,1,io}(\vec{p}^2)}$. We observe that $A(\vec{p}^2)$ goes to 0
as $\vec{p} \to \infty$. Right: a log-plot for three-point diagrams $\Gamma_3$ (in units of $iM_p$), four-point
diagrams $\Gamma_4$ (in units of $iM_p^4$), and five-point diagrams $\Gamma_5$ (in units of $iM_p^9$), where $M_p/M_p$
ranges from 0.1 to 1. The red, green and blue curves represents equation (5.5) for
$N = 3, 4$ and 5, respectively.
In other words, the two-point ‘vertex’ grows more strongly than even the momentum dependence, $\sim e^{\bar{p}}$, of the bare three-point vertex. Also note that the term is finite and therefore it is expected to survive even after we have renormalized the divergent part in the one-loop two-point function. Naively, this may seem like a disaster. For instance, it is easy to see that this leads to an additional divergence in the two-loop diagram, figure 3 (right), which contains the one-loop 2-pt subdiagram. In equation (4.3), since $\Gamma_{1,1}(k^2)$ goes as $e^{\bar{p}}$, the integrand now diverges exponentially as $e^{\bar{p}}$. This is worse than the power law divergence of one-loop! So, does this mean the end of the road for non-local theories as a candidate for quantum gravity? On the contrary, we will now see that this apparent strong exponential dependence may, in fact, be exactly what is needed to make all the higher loops finite!

5. Improved convergence with dressed propagators

5.1. Dressed propagator and one-loop integrals

We saw in the earlier section that additional divergences may arise in higher loops from the one-loop, two-point functions. However, we know that, in quantum field theory, the one-loop correction is only the first term in a sequence of graphs, see figure 6, which can be resummed as a geometric series in the region of convergence and then analytically continued to the entire momentum space. In other words, the bare propagators need to be replaced by the dressed propagator while performing calculations for higher-point Green’s functions or higher loops. Note, that no such infinite sequence exists for interaction vertices, the loop contributions simply add to the bare vertex. Thus, a rather remarkable consequence of this resummation will be that for non-local theories the dressed propagators will be more exponentially suppressed than their bare counterparts at large momentum, and therefore going to overwhelm the exponential enhancements coming from the vertices$^{16}$. In particular, we will explicitly see that this will make the UV part of all higher (than two) point one-loop graphs finite!

The UV part of the two-loop integrals, and here we will only illustrate the two-point function, will also become finite. We will argue that it should be possible to extend this reasoning to all higher loop graphs. In other words, we conjecture that except for the one-loop, two-point function, all graphs in this toy-model for quantum gravity converge in the UV. A more rigorous proof, possibly involving more general coupling (not just cubic), is beyond the scope of this paper and obviously requires further investigation.

The one-loop, two-point contribution schematically reads (see figure 6, top, for a diagrammatic representation):

\[ \cdots \bullet \cdots = \cdots \circ \cdots + \cdots \times \cdots \]

\[ \cdots \circ \cdots = \cdots + \cdots \bullet \cdots + \cdots \bullet \cdots \bullet + \cdots \]

Figure 6. Top: the one-loop, two-point contribution of 1PI diagrams. The cross denotes a counter term vertex. Bottom: the dressed propagator as the sum of an infinite geometric series. The dressed propagator is denoted by the shaded blob.

$^{16}$ This property is more general than just the infinite-derivative theories as finite one-loop results were also obtained for ‘local’ higher-derivative extensions of gravity [52].
where

\[
\begin{align*}
f (\bar{\rho}^2) &= \frac{\bar{\rho}^4}{256\pi^2} \left( -\log \left( \frac{\bar{\rho}^2}{4\pi} \right) - \gamma + 2 \right) + \frac{e^{-\bar{\rho}^2}}{512\pi^2\bar{\rho}^2} \left[ -2e^{2\bar{\rho}^2} (e^{2\bar{\rho}^2} - 1)\bar{\rho}^6Ei (-\bar{\rho}^2) \\
&+ \left( e^{\bar{\rho}^2} - 1 \right) \left( -2(\bar{\rho}^4 + 3\bar{\rho}^2 + 2) + \left( e^{\bar{\rho}^2} - e^{2\bar{\rho}^2} \right) (2\bar{\rho}^4 + 5\bar{\rho}^2 + 4) \right) \right] \\
&+ e^{\bar{\rho}^2} (e^{\bar{\rho}^2} - 1) \bar{\rho}^6Ei \left( -\frac{\bar{\rho}^2}{2} \right) + 2e^{\bar{\rho}^2} \left( 7(\bar{\rho}^4 + \bar{\rho}^2 + 2) \right) \right] \\
&+ \frac{1}{128\pi} \int_0^1 dz \, e^{(1-2z)\bar{\rho}^2} \left[ \bar{t}(r, \bar{\rho})Y_0 \left( 2\sqrt{r - r^2\bar{\rho}^2} \right) \right] \\
&+ u(r, \bar{\rho}) \sqrt{r - r^2} \left( 2\sqrt{r - r^2\bar{\rho}^2} \right). \tag{5.2}
\end{align*}
\]

\(f (\bar{\rho}^2)\) is a regular analytic function of \(\bar{\rho}^2\) which grows as \(e^{3\bar{\rho}^2/2}\) as \(\bar{\rho}^2 \to \infty\). The dressed propagator then represents the geometric series of all the graphs with one-loop, two-point insertions as shown in figure 6 (bottom), analytically continued to the entire complex \(\bar{p}^2\)-plane. Mathematically, this is equivalent to replacing the bare propagator, \(\Pi (\bar{p}^2)\), with the dressed propagator, \(\hat{\Pi} (\bar{p}^2)\):

\[
\hat{\Pi} (\bar{p}^2) = \frac{\Pi (\bar{p}^2)}{1 - \Pi (\bar{p}^2)\Gamma_{2,1c} (\bar{p}^2)} = \frac{-i}{\bar{p}^2e^{\bar{\rho}^2} - \frac{M^4}{M_p^4} f (\bar{\rho}^2)}. \tag{5.3}
\]

Since, in our case, \(\Pi (\bar{p}^2)\) \(\Gamma_{2,1c} (\bar{p}^2)\) grows with large momenta, in the UV limit, we have

\[
\hat{\Pi} (\bar{p}^2) \to \Gamma_{2,1c}^{-1} (\bar{p}^2) \approx \left( 9 - 12\bar{\rho}^{-2} \right)^{-1} e^{-\frac{\bar{\rho}^2}{2}}. \tag{5.4}
\]

Clearly, the dressed propagator is more strongly suppressed than the bare propagator! This is a very crucial result that is now going to ensure that the UV contribution of quantum fluctuations for all the other higher-point one-loop graphs are finite. Since the cubic interactions are known to cause vacuum instability, the mass squared correction is, except for very small \(\bar{\rho}\), negative (as is the case in ordinary \(\phi^3\) theory) leading to an artificial pole in the dressed propagator. This makes all the integrals divergent in the IR. We however, expect this pathology to be cured once higher-order (such as quartic couplings) interactions are included as they must be in a complete gravitational theory. Here, we are concentrating on the UV behavior, and we can bypass this problem by evaluating only the UV part of the integrals, from say \(\bar{\rho} = 1 \ldots \infty\) where the dressed propagator can be approximated by equation (5.4).

Let us now revisit the one-loop calculations of the \(N\)-point diagrams. Once the infinite sum of diagrams leading to the dressed propagators are taken into account, see figure 4 (left), the UV part of the one-loop integral reduces to

\[
\Gamma_{N,UV} \approx \frac{i}{i^N M_p^N} \int \frac{d^4k}{(2\pi)^4} \left[ \frac{V^N (k)}{M_p^N} \right] = \frac{iM^4}{M_p^N} \int \frac{d^4\bar{\ell}}{(2\pi)^4} \left[ \frac{\bar{\ell}^{2N} e^{i\bar{\ell}^2}}{M_p^N f (\bar{\ell})} \right]^N. \tag{5.5}
\]
This integral is finite and we have provided numerical plots as a function of $M/M_p$, see figure 5 (right). We note that the amplitudes remain well behaved even in the limits $M \ll M_p$ and $M_p \ll M$.

5.2. UV convergence of two-loop diagrams

In the previous section we have seen how when we make the transition from the bare to the dressed propagator, the one-loop diagrams in non-local theories become finite. This means that to renormalize at the one-loop level, all we have to do is to renormalize the divergence in the two-point function. This is not very different from the local field theories. For instance, in $\lambda \phi^4$ theory, once the two-point and four-point functions are renormalized, all the higher-point Green’s functions become finite. Can this procedure be extended to all loops though? If the answer is yes, it would provide a tremendous encouragement towards the possibility of having a candidate for an analogue of quantum theory of gravity in the non-local framework. However, in this paper we have to be content with mostly a study of the convergence properties of the two-point two-loop diagrams. We will indeed see that they also become finite as opposed to the $\Lambda^4$ divergence found in equation (3.29).

Consider first the figure 7 (right) that resembles the one-loop, two-point figure 2 (right), except that now the bare propagator has been replaced by the dressed propagator. Again, to determine the finiteness of the graph it is sufficient to focus on the zero external momenta case. The Feynman integral is given by

$$\Gamma_{2,3b} = \frac{i^2}{2^3 M_p^2} \int \frac{d^4 k_1}{(2\pi)^4} \frac{d^4 k_2}{(2\pi)^4} \frac{V^2(k_1) V^2(k_1 - \frac{k_1}{2} + k_2 - \frac{k_2}{2})}{k_1^2 \epsilon_{k_1}^2 - M_p^2 \left( \frac{k_1}{2} \right)^2} \left[ \frac{k_1^2}{2} \epsilon_{k_1}^2 \left( \frac{\epsilon_{k_1}}{\epsilon_{k_1}^2} \right) - M_p^2 \left( \frac{k_1}{2} + k_2 \right)^2 \right]$$

$$\times \left[ \frac{1}{\left( \frac{k_1}{2} - k_2 \right)^2 \epsilon_{k_1}^2 - M_p^2 \left( \frac{k_1}{2} - k_2 \right)^2} \right].$$

(5.6)
Making the redefinition $k_1 \rightarrow k_i, -\frac{h_2}{2} - k_2 \rightarrow k_2$ and $k_3 = -k_2 - k_2$, we get
\[ \Gamma_{2,3b} = \frac{i}{2M_p^2} \int \frac{d^4k_1}{(2\pi)^4} \frac{d^4k_2}{(2\pi)^4} \times \frac{V^2(k_1)V^2(k_1, k_2, k_3)}{k_i^2 e^{\xi_i} - \frac{M^s}{M_p^2} f(k_1)} \left[ k_i^2 e^{\xi_i} e^{\xi_2} - \frac{M^s}{M_p^2} f(k_2) \right] \left[ k_i^2 e^{\xi_3} - \frac{M^s}{M_p^2} f(k_3) \right] \right]. \] (5.7)

To see whether the integrals are convergent or not, we need to look at large values of $k_1, k_2$ where the exponentials dominate. One can check that the integrand goes as
\[ \sim \exp \left[ -\left( \frac{k_1}{2} - k_2 \right)^2 - \frac{7}{4} k_i^2 \right], \] (5.8)

ensuring that both the $k_1$ and $k_2$ integrals are convergent.

The other two-loop diagram for the two-point function, see figure 7 (left), reads as:
\[ \Gamma_{2,3a} = \frac{i^2}{2^3M_p^2} \int \frac{d^4k_1}{(2\pi)^4} \frac{d^4k_2}{(2\pi)^4} \times \frac{V(k_1)V(k_2)V^2(k_1, k_2, k_3)}{k_i^2 e^{\xi_i} - \frac{M^s}{M_p^2} f(k_1)} \left[ k_i^2 e^{\xi_i} e^{\xi_2} - \frac{M^s}{M_p^2} f(k_2) \right] \left[ k_i^2 e^{\xi_3} - \frac{M^s}{M_p^2} f(k_3) \right] \right]. \] (5.9)

where $k_3 = -k_1 - k_2$. The exponential dependence of the integrand as $|k_1|, |k_2| \rightarrow \infty$, goes as
\[ \sim \exp \left[ -\frac{3}{2} \left( \frac{k_1}{3} - \frac{k_2}{3} \right)^2 - \frac{4}{3} k_i^2 \right], \] (5.10)

again leading to a convergent integral.

5.3. Higher vertices and prospects for a finite theory

We have just now seen how strong exponential suppression of the dressed propagator can make the one-loop and two-loop integrals finite. We believe that most likely this remarkable feature continues to higher loops. The basic reason is—even for the one-loop diagrams, the suppression coming from the propagators is stronger than the enhancements coming from the vertices. This ensures two things—first it makes the loops finite, and second the UV growth of
the finite diagrams with respect to the external momenta becomes weaker in every subsequent loops. Thus, finiteness of higher loops is guaranteed recursively. A rigorous proof of the above statement is well beyond the scope of the present paper, but we will now sketch heuristic arguments to demonstrate finiteness of the particular set of two- and three-point diagrams that can be constructed out of lower-loop two- and three-point diagrams, see figure 8.

The basic approach is the following—in order to understand whether any diagram converges in the UV or not, we only need to keep track of the exponential momentum dependences. We already know that the dressed propagators, represented by the shaded blobs, decay in the UV as $e^{-\frac{3k^2}{2}}$. Conservatively, we are therefore going to assume $\Pi(k^2)_{\text{UV}} \rightarrow e^{-\frac{3k^2}{2}}$. The three-point function (represented by the dark blobs) can, on the other hand, be written as

$$\Gamma_3 \rightarrow \sum_{\alpha,\beta,\gamma} e^{\gamma_i^2 + \beta_i^2 + \alpha_i^2},$$

with the convention

$$\alpha \geq \beta \geq \gamma,$$

where $p_1, p_2, p_3$ are the three external momenta. This is because once all the (lower-) loop sub diagrams have been integrated out, what remains are expressions in terms of the corresponding external momenta. Some of these external momenta can then become the internal loop momentum in a subsequent higher loop diagram, see figure 8 for a pictorial representation of the recursive construction.

The sum over the exponents $\{\alpha, \beta, \gamma\}$ in equation (5.11) indicates that there could be many different exponential terms including the permutations needed to symmetrize the vertices over the three internal momenta. We are going to assume that these exponents satisfy certain properties, up to say $(n - 1)$-loops. These conditions will allow us to demonstrate that the loops remain finite. Moreover, we will recursively argue that these properties are also satisfied in the $n$th loop.

### 5.3.1. Two-point diagram.

First, let us look at the zero external momentum limit. It is easy to see that the most divergent UV part of the two-point diagram reads

$$\Gamma_{2,n} \rightarrow \int \frac{d^4k}{(2\pi)^4} \frac{e^{(\alpha_i + \alpha_j + \beta_j)k^2}}{e^{3k^2}},$$

where $k$ is the loop momentum variable in figure 8 (left). We have got two propagators $e^{k^2}$ while the (most divergent UV parts of the) vertex factors originating from lower-loop diagrams are $e^{\alpha_k \beta_k}$ and $e^{\alpha_k \beta_k}$ (we get no $\gamma$s in the exponents, since the external momenta are set equal to zero). Clearly, the integral is finite as long as

$$\alpha_i + \beta_i < \frac{3}{2},$$

where $i = 1, 2$. One can check that the same condition ensures finiteness of the diagram even when one includes non-zero external momenta.

### 5.3.2. Three-point diagram.

First, let us check whether the three-point diagram (see figure 8, right) is finite or not for zero external momenta. Again the most divergent UV contribution comes when the momentum associated with exponents, $\alpha$’s and $\beta$’s, run in the internal loop giving rise to
where $k$ is the loop momentum variable in figure 8, right. Similarly to the argument for the 2-pt function, we have got three propagators $\sigma^2$, while the (most divergent UV parts of the) vertex factors originating from lower-loop diagrams are $e^{\alpha k^2 + \beta k^2}$, $e^{\alpha_2 k^2 + \beta k^2}$ and $e^{\alpha_3 k^2 + \beta k^2}$. Again the integral converges as long as equation (5.14) is valid.

To prove the validity of equation (5.14), let us try to find out how one can get the largest exponents for the external momenta. First, let us consider how one can get the largest sum of the exponents, i.e., $\alpha + \beta + \gamma$. Although, all the arguments below can be conducted for three different sets of exponents in the three three-point vertices making up the one-loop triangle, figure 8 (right), for simplicity, here we will look at what happens when all the three vertices have the same exponents. Clearly, the best way to obtain the largest exponents for the external momenta is to have the $\alpha$ exponent correspond to the external momenta. For a symmetric distribution of $(\beta, \gamma)$ among the internal loops, we get

$$\Gamma_{3,n} \rightarrow \int \frac{d^4k}{(2\pi)^4} \frac{e^{(\alpha_1 + \alpha_2 + \beta + \gamma)k^2}}{e^{\alpha k^2}} , \quad \text{ (5.15)}$$

where $p_1$, $p_2$, $p_3$ are the external momenta for the one-loop triangle, and the superscript in the $\alpha$, $\beta$, $\gamma$ indicates that these are coefficients that one obtains from contributions up to $n-1$ loop level. Before proceeding to obtain the $n$th loop coefficients, let us briefly explain how we got equation (5.16). Assuming symmetrical routing of momenta in the one-loop triangle, we get the propagators $e^{-\frac{1}{2}(k^2 + \frac{p_2^2}{\mu^2})}$, $e^{-\frac{1}{2}(k^2 + \frac{p_3^2}{\mu^2})}$ and $e^{-\frac{1}{2}(k^2 + \frac{p_1^2}{\mu^2})}$, and the vertex factors $e^{\alpha k^2 + \beta k^2 + \gamma k^2}$, $e^{\alpha k^2 + \beta k^2 + \gamma k^2}$, and $e^{\alpha k^2 + \beta k^2 + \gamma k^2}$.

Conservation of momenta then yields equation (5.16). By integrating equation (5.16), we have

$$\alpha^n = \beta^n = \gamma^n = \alpha^{n-1} + \frac{1}{3} \left( \beta^{n-1} + \gamma^{n-1} \right) - \frac{1}{2} . \quad \text{ (5.17)}$$

In particular, for the one-loop, three-point graph, one has to use the three-point bare vertices: $\alpha^0 = 1$ and $\beta^0 = 1$. One then obtains

$$\alpha^1 = \beta^1 = \gamma^1 = \frac{1}{2} , \quad \text{ (5.18)}$$

leading to an overall symmetric vertex: $e^{\frac{1}{2}(p_1^2 + p_2^2 + p_3^2)}$ and $\alpha^1 + \beta^1 + \gamma^1 = \frac{3}{2}$. Since we expect the exponents to decrease as we increase loops, we therefore conjecture that the sum of exponents satisfies the inequality

$$\alpha^n + \beta^n + \gamma^n \leq \frac{3}{2} . \quad \text{ (5.19)}$$

From equation (5.17), we see that this is satisfied provided a further condition is satisfied by the exponents, i.e.:

$$\alpha^{n-1} + \frac{1}{3} (\beta^{n-1} + \gamma^{n-1}) \leq 1 . \quad \text{ (5.20)}$$

To summarize, so far we have shown that if, up to $n - 1$ loops, inequality equation (5.20) is satisfied, then, at the $n$th loop, equation (5.19) is also satisfied. To complete the recursive proof, we must argue that equation (5.20) is also satisfied at $n$-loops. For the loop contribution we are discussing, we have
\[ \alpha^n + \frac{1}{3}(\beta^n + \gamma^n) = \frac{5}{3} \left[ \alpha^{n-1} + \frac{1}{3}(\beta^{n-1} + \gamma^{n-1}) - \frac{1}{2} \right] \leq \frac{5}{6} < 1, \]

and equation (5.20) is indeed satisfied.

One may wonder whether there are other ways of distributing the exponents which could violate equation (5.19). For instance, one can try to maximize \( \alpha^n \) by distributing \( \alpha^{n-1} \) in two of the vertices to run along the internal loop. However, one can check that equation (5.20) still remains valid.

The final point is that the sum of the exponents is maximized by distributing the largest exponents to all the external momentum, in particular making all the exponents positive thereby ensuring that equation (5.19) follows from equation (5.19). While we do not yet have a rigorous proof of these above arguments, in all the cases we have looked at so far, the inequalities, equations (5.14), (5.19) and (5.20) seem to hold up.

6. Summary and future research directions

In this paper, we studied the quantum loops for an infinite-derivative scalar field theory action as a toy model to mimic the UV properties of the BGKM gravity [24], which is ghost-free at tree-level (see [36] for a discussion of unitarity in infinite-derivative theories). Expanding the BGKM action around the Minkowski vacuum, one can obtain, for instance, the ‘free’ part that determines the propagator from the \( \mathcal{O}(\hbar^2) \) terms, while the \( \mathcal{O}(\hbar^3) \) terms determine the cubic interaction vertices. Unfortunately, \( \mathcal{O}(\hbar^3) \) terms are technically challenging and some of the expression involves double sums. Instead of getting involved with too many technicalities, we therefore chose to work with a simple toy model action, equation (2.23), that respects a combination of the shift and scaling symmetry at the level of equation of motion that lets us capture some of the essential features of BGKM gravity such as the compensating nature of the exponential suppression in the propagator and the exponential enhancement in the vertex factor.

Of course, in order to formulate a consistent, UV-complete nonlocal theory of quantum gravity, we should discuss the spin-2 part of the graviton propagator (the corresponding exponential enhancements from the vertices would also include rank-2 tensors). The current paper merely captures some aspects of an infinite-derivative theory of gravity. By no means is our current analysis complete and can only be considered as a step towards formulating a nonlocal infinite-derivative theory of gravity. However, there is a general belief that nonlocality may be able to tame the quantum divergences in gravity that remain one of the outstanding challenges of theoretical physics.

Higher-derivative theories, typically, suffer from the problem of ghosts of the Ostrogradsky instabilities, as discussed quite elaborately by Eliezer and Woodard in [26]. The ghosts typically arise as extra poles in the propagator, while the Ostrogradsky argument relies on having a highest ‘momentum’ associated with the highest derivative in the theory in which the energy is seen to be linear, as opposed to quadratic. However, the ‘BGKM’ model contains an infinite set of derivatives where no such highest momentum operator can be readily identified, nor are their any extra poles in the propagator which could correspond to new degrees of freedom ghosts or otherwise. This is the reason why we believe that the BGKM theory may be ghost-free. We would like to note that the presence of ghosts typically shows up as classical instabilities. So far, our studies involving certain classical cosmological backgrounds [21], have shown that the perturbations remain under control and do not show any instabilities. Also, we are currently investigating the issue of unitarity more explicitly by
looking into scattering processes and revisiting the optical theorem for these theories as there remain certain technical and subtle considerations involving analytic continuation and the use of CPV theorem.

Even in ordinary field theory, integrals are irregular and one always needs to come up with prescriptions (such as Wick rotation or the $i\epsilon$ prescription) to make sense of the integrals. In other words, quantum field theories have to be supplemented with rules that define what an integral is as the usual rules simply do not work. The same is true for the nonlocal models, in fact, largely our paper can be thought of as an attempt to find prescriptions/defining rules that makes the loop integrals well defined and hopefully (after renormalization of the one-loop divergences) finite. All we can say is that, so far, in the loops that we have looked at, our prescription seems to be giving us well defined results which bodes well for future. Whether these prescriptions can be carried forward to higher and higher loops and in the actual theory of gravity obviously remains an open question.

We derived the Feynman rules for our toy model action, i.e., the propagator and the vertex factors. Consequently, we computed the one-loop, two-point diagram, both with zero and arbitrary external momenta, which gives a $\Lambda^4$ divergence, where $\Lambda$ is a momentum cutoff. The two-loop diagrams with zero external momenta also give a $\Lambda^4$ divergence, suggesting that we do not get new divergences as we proceed from one-loop to two-loop. We repeated our one-loop and two-loop computations with external momenta, and we paid extra care in understanding the one-loop, two-point function which appears as a subdivergence in higher-loop diagrams. Typically, in the one-loop, two-point function, we obtain a $\frac{1}{\epsilon^2}$ external momentum dependence in the UV which indicates that, for $\vec{p}^2 \to \infty$, the one-loop, two-point function tends to infinity. This may appear as an initial setback, but, actually, this external momentum dependence is what, we believe, makes all higher-loop and higher-point diagrams finite once the bare propagators are replaced with the dressed propagators. This becomes possible because the exponential suppression in the dressed propagator overcomes the exponential enhancement originating from the vertices. The one-loop, $N$-point functions with zero external momenta become UV-finite, as do the two-loop integrals for vanishing external momenta. We believe that, even in the case of arbitrary external momenta, our results will not change; the higher-loop diagrams also become UV-finite with the use of the dressed propagators. The basic reason is that, even for the one-loop diagrams, the suppression coming from the propagators is stronger than the enhancements coming from the vertices. This ensures two things—first, it makes the loops finite and, second, the UV growth of the finite diagrams with respect to the external momenta becomes weaker in every subsequent loops. Thus, finiteness of higher loops is ensured recursively.

To illustrate this general argument, we considered the finiteness of $n$-loop, two-point and three-point diagrams that can be constructed out of lower-loop two-point and three-point diagrams. We found strong arguments, but not rigorous proofs, to support that, once the one-loop divergences are tamed, all other higher-loop and higher-point functions may become finite. Whether these results can be transferred to a complete theory of gravity is indeed an open question, but it is a question worth exploring, at the very least. This is already an encouraging sign for an infinite-derivative action of scalar toy model, which can now make higher loops finite, giving us a ray of hope to tackle the problem in full glory for the BGKM gravity. However, as a future computation, it would be interesting to first demonstrate that the finiteness of the diagrams hold to all orders in loops for any $N$-point diagrams. A full proof even for an infinite-derivative toy model is beyond the scope of this current paper, and we will carry on this computation elsewhere.

Appendix A. The BRST-invariant gravitational action and superficial degree of divergence

If we consider metric fluctuations around the Minkowski background

\[ g_{\mu\nu} = \eta_{\mu\nu} + h_{\mu\nu}, \]  

within the harmonic gauge, we can define the quantum theory with:

\[ \partial_\nu \tilde{h}^{\mu\nu} = 0, \]

where

\[ \tilde{h}_{\mu\nu} = h_{\mu\nu} - \frac{1}{2} \eta_{\mu\nu} h \Rightarrow \tilde{h}^{\mu\nu} = h^{\mu\nu} - \frac{1}{2} \eta^{\mu\nu} h. \]

\( \tilde{h}_{\mu\nu} \) is called the trace-reverse of \( h_{\mu\nu} \) since

\[ h_{\mu\nu} = -\tilde{h}^{\nu\mu} h. \]

Furthermore, \( h_{\mu\nu} = \frac{1}{2} \eta_{\mu\nu} \tilde{h} \).

The quantized BGKM action must contain:

\[ S_{\text{quantized}} = S + S_{\text{GF}} + S_{\text{ghost}} \]

\[ = S_{\text{EH}} + S_{Q} + \frac{1}{2} \int d^4x \left( F \mathcal{F}(\Box) F^\tau + \int d^4x \tilde{C}_\mu D^\mu \partial_\nu C^\nu \right). \]

where \( S_{\text{EH}} + S_{Q} \) is the gravitational action (see equation (2.6)), \( S_{\text{EH}} \) is given by equation (2.7) and \( S_{Q} \) is given by equation (2.8). \( S_{\text{GF}} \) is the gauge-fixing term and \( S_{\text{ghost}} \) is the ghost-antighost action while \( \xi \) is a finite parameter. We have that \( F^\tau = \tilde{F}_\mu h^{\mu\nu} \) and \( \tilde{F}_\mu = \delta^\nu_\tau \tilde{F}_\mu \eta^{\mu\nu} - \frac{1}{2} \delta^\nu_\tau \eta^{\mu\nu} \tilde{h}_{\mu\nu} \) (the arrow indicates the direction in which the derivative acts).

\( C^\nu \) is the ghost field and \( \tilde{C}_\mu \) is the antighost field; both are anticommuting. \( D^\mu \) is the operator generating gauge transformations in the graviton field \( h^{\mu\nu} \), given an arbitrary infinitesimal vector field \( \xi^\nu(x) \) (corresponding to \( x^\mu = x^\mu - \xi^\mu \)).

That is,

\[ \partial_\nu h_{\mu\nu} = \mathcal{L}_\xi g_{\mu\nu} = \xi^\rho \partial_\rho g_{\mu\nu} + g_{\mu\rho} \partial_\rho \xi^\nu + g_{\nu\rho} \partial_\rho \xi^\mu + D_{\mu\nu} \xi^\rho, \]

where \( \mathcal{L} \) is the Lie derivative and

\[ D_{\mu\nu} \xi^\rho = \partial_\rho \xi^\mu + \partial_\mu \xi^\nu + h_{\mu\alpha} \partial_\alpha \xi^\nu + h_{\nu\alpha} \partial_\alpha \xi^\mu + \partial_\nu \xi^\mu + \partial_\mu \xi^\nu. \]

Accordingly

\[ D_{\mu\nu} = \eta_{\alpha\nu} \partial_\alpha + \eta_{\mu\nu} \partial_\nu + h_{\alpha\nu} \partial_\alpha + h_{\mu\nu} \partial_\mu + \partial_\mu h_{\nu\rho}. \]

We can raise indices in (A.5) using the Minkowski tensors.

Moreover, \( \mathcal{F} \) is an analytic function of \( \Box \):

\[ \mathcal{F}(\Box) = \sum f^\nu_n = 0^\nu_n \Box^\nu_n, \]

where \( f^\nu_n \) are real coefficients.
If we change the gauge-fixing term to read \( F^T = e'(x) \) \[44\], with \( e'(x) \) an arbitrary four-vector function, we can smear out the gauge condition with a weighting functional. Choosing the weighting functional
\[
\omega(e') = \exp \left[ i \left( \frac{1}{2\xi} \int \! \! d^4x \; e_x \mathcal{F}(\Box)e' \right) \right].
\]
\( \xi \) is a finite parameter, we obtain the gauge-fixing term (see \[28, 44\] for a derivation of the gauge-fixing term in non-local theories)
\[
S_{GF} = \frac{1}{2\xi} \int \! \! d^4x \; F_x \mathcal{F}(\Box) F^T.
\]

The ghost-antighost action is given by
\[
S_{\text{ghost}} = \int \! \! d^4x \; \bar{C}_x e^{*}_{\mu \nu} C^\alpha_{\mu \nu},
\]
folowing the usual prescription \[53, 54\].

Hereafter, repeated indices denote both summation over the discrete values of the indices and integration over the spacetime arguments of the functions or operators indexed.

The BRST transformations for Yang–Mills theories express a residual symmetry of the effective action which remains after the original gauge invariance has been broken by the addition of the gauge-fixing and ghost action terms \[44\]. The BRST transformations for BGKM gravity, appropriate for the gauge-fixing term, \( S_{GF} \), are given by
\[
\begin{align*}
\delta_{\text{BRST}} h^\mu{}^\nu &= D^\mu{}_{\alpha} C^\alpha \delta \lambda, \\
\delta_{\text{BRST}} C^\alpha &= - \partial_\beta C^\alpha C^\beta \delta \lambda, \\
\delta_{\text{BRST}} \bar{C}_T &= \frac{1}{\xi} \mathcal{F}(\Box) F_x \delta \lambda,
\end{align*}
\]
where \( \delta \lambda \) is an infinitesimal anticommuting constant parameter. The BRST transformation of the gravitational field is just a gauge transformation of \( h^\mu{}^\nu \) generated by \( C^\alpha \delta \lambda \); thus, gauge-invariant functionals of \( h_{\mu \nu} \), like \( S \), are BRST-invariant. The transformation of \( C^\alpha \) is nilpotent
\[
\delta_{\text{BRST}} \left( \partial_\beta C^\alpha C^\beta \right) = 0,
\]
while the transformation of \( h^\mu{}^\nu \) is also nilpotent:
\[
\delta_{\text{BRST}} \left( D^\mu{}_{\alpha} C^\alpha \right) = 0
\]
Since the only part of the ghost action which varies under the BRST transformations is the antighost, \( \bar{C}_T \), we have chosen the BRST transformation of the antighost such that the variation of the ghost action cancels the variation of the gauge-fixing term. Hence, \( S_{\text{quantized}} \) is BRST-invariant.

If we also include BRST-invariant couplings of the ghosts and gravitons to some external fields \( K_{\mu \nu} \) (anti-commuting) and \( L_{\sigma} \) (commuting), we obtain the effective action \( \tilde{S} \), as:
\[
\tilde{S} = S_{\text{quantized}} + K_{\mu \nu} D^\mu{}_{\alpha} C^\alpha + L_{\sigma} \partial_\beta C^\alpha C^\beta,
\]
where \( \tilde{S} \) is also BRST-invariant.

Now, we want to compute the superficial degree of divergence for the BRST-invariant BGKM action, where we have made the choices \( \mathcal{F}_3(\Box) = 0 \) and \( \mathcal{F}_1(\Box) = \frac{e^{1/2\Box} - 1}{\Box} = -\frac{\mathcal{F}(\Box)}{2} \)

\[
\begin{align*}
Class. Quantum Grav. 32 (2015) 215017
S Talaganis et al
\end{align*}
\]
in equations (2.8), (2.9) and \( \mathcal{F}(\Box) = e^{-\Box/M^2} \). To proceed, let us introduce the following notations:

- \( n_h \) is the number of graviton vertices,
- \( n_G \) is the number of anti-ghost-graviton-ghost vertices,
- \( n_K \) is the number of \( K \)-graviton-ghost vertices,
- \( n_L \) is the number of \( L \)-ghost-ghost vertices,
- \( I_h \) is the number of internal graviton propagators,
- \( I_G \) is the number of internal ghost propagators,
- \( I_C \) is the number of external ghosts,
- \( E_C \) is the number of external anti-ghosts.

By counting the exponential contributions of the propagators and the vertex factors, as discussed in section 2.2, we can now obtain the superficial degree of divergence, which is given by

\[
E = n_h - I_h, \tag{A.16}
\]

where \( n_h \) is the number of graviton vertices, and \( I_h \) is the number of internal graviton propagators. By using the following topological relation

\[
L = 1 + I_h + I_G - n_h - n_G - n_K - n_L, \tag{A.17}
\]

we get

\[
E = 1 - L + I_G - n_G - n_K - n_L. \tag{A.18}
\]

Employing the momentum conservation law for ghost and anti-ghost lines

\[
2I_G - 2n_G = 2n_L + n_K - E_C - E_C, \tag{A.19}
\]

we obtain

\[
E = 1 - L - \frac{1}{2}(n_K + E_C + E_C). \tag{A.20}
\]

Note that, as \( n_K, E_C \) and \( E_C \) increase, the degree of divergence decreases. Therefore, the most divergent diagrams are those for which \( n_K = E_C = E_C = 0 \), i.e., the diagrams whose external lines are all gravitons. In this case, the degree of divergence is given by:

\[
E = 1 - L. \quad \text{For } L \geq 2, E < 0 \text{ and the corresponding loop amplitudes are superficially convergent.}
\]

### Appendix B. Types of terms originating from the gravitational action

If we compute the \( \mathcal{O}(\hbar^3) \) part of the Einstein–Hilbert action, \( S_{EH} \) (see equation (2.7)), we obtain the following type of term:

\[
h\partial_{\mu}\hbar\partial^{\mu}\hbar. \tag{B.1}
\]

Now, let us compute the \( \mathcal{O}(\hbar^3) \) part of the BGKM action, \( S_Q \) (see equation (2.8)), keeping in mind that \( \sqrt{-g} = 1 + \frac{1}{2}h + \frac{1}{8}h^2 - \frac{1}{2}h_{\mu}^\nu h^\nu_{\mu} + \mathcal{O}(\hbar^3) \), where \( h = \eta_{\mu}^\nu h_{\mu\nu} \).

We shall need the following relation for the double sums appearing in the last two lines of equation (B.3), see below:

\[
T\delta(\Box^n)S = \sum_{m=0}^{n-1} \Box^m T\delta(\Box)\Box^{n-m-1}S, \tag{B.2}
\]
where \( n \geq 1 \). \( \delta(\Box) \) indicates the variation of the \( \Box \) operator and \( \delta(\Box^n) \) indicates the variation of the \( \Box^n \) operator. \( S \) and \( T \) are tensors constructed out of the Riemann curvatures and the metric.

Then, by applying integration by parts where appropriate

\[
\begin{align*}
S_{(3)} &= \int d^4 x \frac{1}{2} h \left[ R^{(1)} \mathcal{F}_1(\Box) R^{(1)} + R^{(1)}_{\mu \nu} \mathcal{F}_2(\Box) R^{(1) \mu \nu} + R^{(1)}_{\mu \nu \lambda \sigma} \mathcal{F}_3(\Box) R^{(1) \mu \nu \lambda \sigma} \right] \\
&\quad + \int d^4 x \left[ 2 R^{(2)} \mathcal{F}_1(\Box) R^{(1)} + R^{(1)}_{\mu \nu} \mathcal{F}_2(\Box) R^{(2) \mu \nu} + R^{(2)}_{\mu \nu \lambda} \mathcal{F}_3(\Box) R^{(1) \mu \nu \lambda} \right] \\
&\quad + \sum_{n=0}^{n-1} \int d^4 x \left[ f_{h n} \Box^n \delta(\Box) \Box^{n-m-1} R^{(1)} + f_{h n} \Box^n R^{(1) \mu \nu \lambda \sigma} \delta(\Box) \Box^{n-m-1} R^{(1) \mu \nu \lambda \sigma} \right],
\end{align*}
\]

where \( \mathcal{F}_i(\Box) = \sum_{n=0}^{\infty} f_n \Box^n \), \( i = 1, 2, 3 \), and \( \Box = \eta^{\mu \nu} \partial_\mu \partial_\nu \). We have that \( R^{(1) \mu \nu} = \partial_\alpha \Gamma^{\mu \nu}_\alpha - \partial_\mu \Gamma^{\nu \alpha}_\alpha + \Gamma^{\mu \alpha}_\lambda \Gamma^{\nu \lambda}_\alpha - \Gamma^{\nu \lambda}_\rho \Gamma^{\mu \lambda}_\rho \). Moreover, \( R^{(2)} = R^{(2) \mu \nu} \) and \( R = g^{\mu \nu} R_{\mu \nu} \).

When we lower or raise an index in the Riemann tensors, that is always done with the use of

\[
g_{\mu \nu} = \eta_{\mu \nu} + h_{\mu \nu}
\]

and

\[
g^{\mu \nu} = \eta^{\mu \nu} - h^{\mu \nu} + \ldots,
\]

respectively. For instance, \( R^{(2) \mu \nu} = \eta^{\rho \sigma} \eta^{\mu \sigma} R^{(2) \rho \sigma} - 2 \eta^{\rho \sigma} h^{\mu \sigma} R^{(1) \rho \sigma} \) and \( R^{(2)} = \eta^{\mu \nu} R^{(2) \mu \nu} - h^{\mu \nu} R^{(1) \mu \nu} \).

Let us mention that

\[
R^{(1)}_{\mu \nu \lambda \sigma} = \frac{1}{2} \left( \partial_\nu \partial_\lambda h_{\mu \sigma} + \partial_\nu \partial_\sigma h_{\mu \lambda} - \partial_\mu \partial_\lambda h_{\nu \sigma} - \partial_\mu \partial_\sigma h_{\nu \lambda} \right),
\]

\[
R^{(1)}_{\mu \nu} = \frac{1}{2} \left( \partial_\nu \partial_\mu h^{\sigma \sigma} + \partial_\nu \partial_\sigma h^{\mu \sigma} - \partial_\mu \partial_\sigma h^{\nu \sigma} \right),
\]

\[
R^{(1)} = \partial_\mu \partial_\nu h^{\mu \nu} - \Box h.
\]

Following the same method, we can derive the \( O(h^2) \) expressions for the Riemann tensors.

The terms involving double sums give rise to technical complications when evaluating the Feynman loop integrals. While several \( \mathcal{F}^\prime \)’s can satisfy equation (2.10), following BGKM [24], we have:

\[
a(\Box) = e^{-\Box/M^2} \quad \text{and} \quad \mathcal{F}_3(\Box) = 0 \Rightarrow \mathcal{F}_1(\Box) = \frac{e^{-\Box/M^2} - 1}{\Box} = -\frac{\mathcal{F}_2(\Box)}{2},
\]

\( a(\Box) \) having been defined in equation (2.11) and \( M \) being a mass scale at which the infinite-derivative modifications become important. Hence, we obtain a ghost-free, infinite-derivative quantum gravitational action, given by [24, 25]

\[
S_{QG} = \int d^4 x \sqrt{-g} \left\{ \frac{R}{2} + R \left[ \frac{e^{-\Box/M^2} - 1}{\Box} \right] R - 2R_{\mu \nu} \left[ \frac{e^{-\Box/M^2} - 1}{\Box} \right] R^{\mu \nu} \right\}.
\]

Making these assumptions and enforcing a conformal flatness condition, \( h_{\mu \nu} = \Omega^2(x) \eta_{\mu \nu} \), where \( \Omega(x) \) is a smooth, strictly positive function (\( \Omega^2 = h/4 \) in four-dimensional spacetime), in order to get scalar-type gravitational terms, we obtain the following types of \( O(h^3) \) terms:
\[
\partial_\mu h \partial_\nu h \left( \frac{a(\Box) - 1}{\Box} \right) \partial_\rho \partial_\sigma h, \quad h \partial_\mu h \left( \frac{a(\Box) - 1}{\Box} \right) \Box h, \\
h \partial_\mu h \partial_\nu h \left( \frac{a(\Box) - 1}{\Box} \right) \partial_\rho \partial_\sigma h, \quad h \Box h \left( \frac{a(\Box) - 1}{\Box} \right) \Box h. \quad (B.9)
\]

Inspired by the BGKM action (B.8), we wish to construct a scalar field theory toy model that will capture its essential properties and behavior. After integration by parts, the terms in equation (B.9) which are relevant to the construction of such a scalar field theory toy model, are

\[
h \partial_\mu h \partial_\nu h, \quad h \Box h (\Box) h, \quad h \partial_\mu h (\Box) \partial_\rho h. \quad (B.10)
\]

Therefore, if we choose the free part, \( S_{\text{free}} \), of the action of our scalar field theory toy model (\( \phi \) is the scalar field) of equation (2.18) (so that the propagator shall have an exponential suppression), the interaction part, \( S_{\text{int}} \), will be of the form

\[
S_{\text{int}} = \frac{1}{M_p} \int d^4x \left( \alpha_1 \phi \partial_\mu \phi \partial^\mu \phi + \alpha_2 \phi \Box \phi a(\Box) \phi + \alpha_3 \phi \partial_\mu \phi a(\Box) \partial_\rho \phi \right), \quad (B.11)
\]

where \( \alpha_1, \alpha_2 \) and \( \alpha_3 \) are real coefficients.

**Appendix C. Arriving at the toy model action**

We start with

\[
S_{\text{free}} = \frac{1}{2} \int d^4x \left( \phi \Box a(\Box) \phi \right) \quad (C.1)
\]

and

\[
S_{\text{int}} = \frac{1}{M_p} \int d^4x \left( \alpha_1 \phi \partial_\mu \phi \partial^\mu \phi + \alpha_2 \phi \Box \phi a(\Box) \phi + \alpha_3 \phi \partial_\mu \phi a(\Box) \partial_\rho \phi \right). \quad (C.2)
\]

We want the equation of motion of \( S_{\text{scalar}} = S_{\text{free}} + S_{\text{int}} \) to satisfy the following symmetry: \( \phi \rightarrow (1 + \epsilon) \phi + \epsilon \). This requirement will fix the values of the coefficients \( \alpha_1, \alpha_2 \) and \( \alpha_3 \).

After integrating by parts, we can write \( S_{\text{free}} \) and \( S_{\text{int}} \), as follows:

\[
S_{\text{free}} = \int d^4x \left( \frac{1}{2} \phi \Box \phi + \frac{1}{2} \phi \Box a(\Box) \phi \right), \quad (C.3)
\]

\[
S_{\text{int}} = \int d^4x \left[ \left( \alpha_1 + \alpha_3 - 2 \alpha_2 \right) \phi \partial_\mu \phi \partial^\mu \phi + \alpha_2 \phi \Box \phi a(\Box) \phi + \alpha_3 \phi \partial_\mu \phi a(\Box) \partial_\rho \phi \right]. \quad (C.4)
\]

where

\[
\bar{a}(\Box) = a(\Box) - 1. \quad (C.5)
\]

Hence, \( S_{\text{scalar}} \) can be written as

\[
S_{\text{scalar}} = \int d^4x \left( \frac{1}{2} \phi \Box \phi + \frac{1}{M_p} \left( \alpha_1 + \alpha_3 - 2 \alpha_2 \right) \phi \partial_\mu \phi \partial^\mu \phi \right)
\]

\[
+ \int d^4x \left( \frac{1}{2} \phi \Box a(\Box) \phi + \frac{1}{M_p} \left( \alpha_2 \phi \Box \phi a(\Box) \phi + \alpha_3 \phi \partial_\mu \phi a(\Box) \partial_\rho \phi \right) \right). \quad (C.6)
\]
Each of the two lines in equation (C.6), when considered separately, should have invariant equations of motion under the symmetry: \( \phi \rightarrow (1 + \epsilon) \phi + \epsilon \). Let us write \( S_{\text{scalar}} \) as
\[
S_{\text{scalar}} = S_1 + S_2,
\]
where \( S_1 \) is the first line in (C.6), and \( S_2 \) is the second line in (C.6).

If we vary \( S_1 \), we obtain
\[
\delta S_1 = \int d^4x \left( \epsilon \phi \Box \phi + \frac{\epsilon}{2} \Box \phi + \frac{1}{M_p} \left( 3 \epsilon (\alpha_1 + \alpha_3 - 2 \alpha_2) \phi \partial_{\mu} \phi \partial^{\mu} \phi \right. \\
+ \left. \epsilon (\alpha_1 + \alpha_3 - 2 \alpha_2) \partial_{\mu} \phi \partial^{\mu} \phi \right) \right)
\]
\[
= \int d^4x \left( \epsilon (1 + 2 \alpha_2 - \alpha_1 - \alpha_3) \phi \Box \phi + \frac{3 \epsilon}{M_p} (\alpha_1 + \alpha_3 - 2 \alpha_2) \phi \partial_{\mu} \phi \partial^{\mu} \phi \right),
\]
up to a total divergence and after integrating by parts, it should be proportional to \( S_1 \). Therefore, we should have
\[
1 + 2 \alpha_2 - \alpha_1 - \alpha_3 = \frac{3}{2}.
\]

Now, varying \( S_2 \) yields
\[
\delta S_2 = \int d^4x \left( \epsilon \phi \Box \phi + \frac{\epsilon}{2} \Box \phi + \frac{3 \epsilon}{M_p} \alpha_2 \phi \Box \phi \partial(\Box) \phi + \alpha_2 \Box \phi \partial(\Box) \phi \\
+ \frac{3 \epsilon}{M_p} \alpha_3 \partial_{\mu} \phi \partial(\Box) \partial^{\mu} \phi + \alpha_3 \partial_{\mu} \phi \partial(\Box) \partial^{\mu} \phi \right)
\]
\[
= \int d^4x \left( \epsilon (1 + \alpha_2 - \alpha_3) \phi \Box \phi + \frac{1}{M_p} (3 \alpha_2 \phi \Box \phi \partial(\Box) \phi \\
+ 3 \alpha_3 \phi \partial_{\mu} \phi \partial(\Box) \partial^{\mu} \phi) \right),
\]
up to a total divergence and after integration by parts. Again, it should be proportional to the original action, so
\[
1 + \alpha_2 - \alpha_3 = \frac{3}{2}.
\]

From equations (C.9) and (C.11), we get
\[
\alpha_1 = \alpha_2 = - \alpha_3 = \frac{1}{4}.
\]

As a result
\[
S_{\text{int}} = \frac{1}{M_p} \int d^4x \left( \frac{1}{4} \phi \partial_{\mu} \phi \partial^{\mu} \phi + \frac{1}{4} \phi \Box \phi \alpha (\Box) \phi - \frac{1}{4} \phi \partial_{\mu} \phi \alpha (\Box) \partial^{\mu} \phi \right).
\]
Appendix D. Loop integrals

D.1. One-loop integrals with arbitrary external momenta

To compute one-loop, two-point integral with arbitrary external momenta, \( p \) and \(-p\), we have:

\[
\int \frac{d^4k}{(2\pi)^4} f(p, k),
\]

where \( f \) is a function of the external momentum \( p \), and the loop momentum \( k \). We analytically continue the integrand, so that we can work in the Euclidean space:

\[
d^4k \rightarrow i d^4k, \quad k^2 \rightarrow k_E^2, \quad p \cdot k \rightarrow (p \cdot k)_E, \quad p^2 \rightarrow p_E^2,
\]

since \( k_0 \rightarrow ik_0 \), and \( p_0 \rightarrow ip_0 \). Then, by spherical symmetry, we express \( d^4k_E \) as

\[
4\pi k_E^2 \sqrt{1 - x^2} \, dx \, dk_E,
\]

where \( x \) is the angle between \( p_E \) and \( k_E \). We assume \( p_E \) to be the z-axis, so \( p_E \cdot k_E = p_E k_E x \) and \( p_E \) and \( k_E \) are the norms of \( p_E \) and \( k_E \).

We then integrate with respect to \( x \) from \(-1\) to \( 1 \). If the integral converges, we subsequently integrate with respect to \( k_E \) from \( 0 \) to \( \Lambda \), where \( \Lambda \) is the momentum cutoff.

D.2. Two-loop integrals with zero external momenta

Let us compute the integral resulting in equation (3.22). The integral is given by:

\[
\int \frac{d^4k_1}{(2\pi)^4} \frac{d^4k_2}{(2\pi)^4} \frac{(k_1^2 + k_2^2 + k_3^2)}{16M_p^4 k_1^2 k_2^2 k_3^2} e^{k_1^2/2M^2} e^{-(k_1 - k_3)^2/2M^2}. \tag{D.4}
\]

This can be written as

\[
\frac{1}{16M_p^4} \int_0^\Lambda \, da \int_0^\infty \, db \times \int_{-1}^1 \, dx \frac{\sqrt{1 - x^2}}{16(2\pi)^3 a^2 b^2 (a^2 + b^2 + 2abx)^{1/2}} \exp \left( \frac{a^2}{2M^2} \right) \exp \left( \frac{b^2}{2M^2} \right), \tag{D.5}
\]

where \( x \) is the cosine of the angle between \( k_1 \) and \( k_2 - k_3 \), \( a \) is the norm of \( k_1 \) in the Euclidean space, and \( b \) is the norm of \( k_2 - k_3 \) in the Euclidean space. The factor \( 1/16 \) in front of the integral is the Jacobian \( \left( \frac{1}{2} \right)^4 \).

17 In Minkowski space (mostly plus metric signature), \( k^2 = -k_0^2 + k^2 \), where \( k_0 = k_1^2 + k_2^2 + k_3^2 \). After analytic continuation, \( k_E^2 = k_0^2 + k^2 \), where \( k_0 = -ik_\phi \).
Integrating with respect to \( x \) from \(-1\) to \(1\), we get
\[
\frac{1}{2048 \pi^5 M_p^2} \int_0^\lambda da \int_0^\infty db \frac{\pi \left( a^2 + b^2 - (a + b)(a - b) \right)}{4a^2b^2(a^2 + b^2)} ab^3 \left( 3a^2 + b^2 \right)^2 \times \exp \left( \frac{a^2}{2M^2} \right) \exp \left( -\frac{b^2}{2M^2} \right).
\] (D.6)

The integration with respect to \( b \) is split into two parts: (i) from 0 to \( a \) and (ii) from \( a \) to \( \infty \).

The first part becomes \((a^2 + b^2 - (a + b)(a - b) = 2b^2)\)
\[
\frac{1}{4096 \pi^4 M_p^2} \int_0^\lambda da \int_0^a db \frac{b^3}{a(a^2 + b^2)} \left( 3a^2 + b^2 \right)^2 \exp \left( \frac{a^2}{2M^2} \right) \exp \left( -\frac{b^2}{2M^2} \right). \] (D.7)

and gives
\[
\frac{1}{4096 \pi^4 M_p^2} \int_0^\lambda da \frac{-2}{a} \left( M^2 - a^2 M^2 \left( 7 - 5e^{\frac{a^2}{2M^2}} \right) - 4M^4 \left( e^{\frac{a^2}{2M^2}} - 1 \right) + a^4 \left( 5 - 2e^{\frac{a^2}{2M^2}} \right) \right) + a^2 e^{\frac{a^2}{2M^2}} Ei \left( -\frac{a^2}{M^2} \right) - a^4 e^{\frac{a^2}{2M^2}} Ei \left( -\frac{a^2}{2M^2} \right)).
\] (D.8)

The second part becomes \((a^2 + b^2 - (a + b)(b - a) = 2a^2)\)
\[
\frac{1}{4096 \pi^4 M_p^2} \int_0^\lambda da \int_a^\infty db \frac{ab}{a^2 + b^2} \left( 3a^2 + b^2 \right)^2 \exp \left( \frac{a^2}{2M^2} \right) \exp \left( -\frac{b^2}{2M^2} \right). \] (D.9)

and gives
\[
\frac{1}{4096 \pi^4 M_p^2} \int_0^\lambda da \frac{1}{4} \left( 24a^2 M^2 + 8M^4 - 8a^4 e^{\frac{a^2}{2M^2}} Ei \left( -\frac{a^2}{M^2} \right) \right). \] (D.10)

In (D.8), there are (four) terms which diverge exponentially; those terms are the terms in the integrand involving \(-5e^{\frac{a^2}{2M^2}}, e^{\frac{a^2}{2M^2}} - 1, -2e^{\frac{a^2}{2M^2}}\) and \(-a^2 e^{\frac{a^2}{2M^2}} Ei(-\frac{a^2}{2M^2})\). For those terms, we first write \(M^2 = -\bar{M}^2\) and then analytically continue back the integrals to obtain them as a function of \(\bar{M}^2\). We should mention that we get \(\Lambda^2, \Lambda^2\) and \(\log \left( \frac{\Lambda^2}{\bar{M}^2} \right)\) divergences after we apply that prescription in (D.8). The full result is

\[18\] We note that the loop integrals in the type of nonlocal theories we are considering are always ill-defined in Minkowski space-time; this is because a term such as \(e^{\frac{\pi^2}{2M^2}} = e^{\pi \bar{M}^2} e^{\frac{\pi^2}{2M^2}}\) is always divergent either in the space or the time direction depending upon the sign of \(M^2\). Thus, these integrals only make sense once appropriately ‘Euclideanized’ and then analytically continued back to Minkowski space-time. While going to Euclidean space, we always have a choice, either \(t \to it\), or \(x \to ix\), and that depends on the overall sign of the exponents. When we write \(M^2 = -\bar{M}^2\) in appendix D.2, we simply mean that rather than \(t \to it\), we choose \(x \to ix\). And, as we have now checked, once the integrals are evaluated correctly, we do not find any inconsistencies, all the loop amplitudes are purely imaginary leading to terms that are real in the effective action. Perhaps it is also worth pointing out that the analytic continuations followed here is not new, and has been used in previous nonlocal quantum field theory literature with consistent results. In particular, in both [38, 42], it was also shown that, in the \(M^2 \to \infty\) limit, one recovers the local field theory results, as it should.
\[
\frac{M^2}{8192\pi^4\lambda^2} \left( -4\lambda^4 - 4(5 + \gamma)\lambda^4 - 18\lambda^2 M^2 - 2e^{\frac{-\lambda^2}{2M^2}}(\lambda^4 - 2\lambda^2 M^2 + 2M^4)E_{1\gamma} \left( -\frac{\lambda^2}{M^2} \right) \right) \\
+ 8M^4 \left( \frac{1}{2} E_{1\gamma} \left( -\frac{\lambda^2}{2M^2} \right) + \log \left( \frac{2M^2}{\lambda^2} \right) \right) + 20M^4 e^{-\frac{\lambda^2}{2M^2}} - 4\lambda^2 M^2 e^{-\frac{\lambda^2}{2M^2}} \\
+ 4\lambda^2 M^2 e^{-\frac{\lambda^2}{2M^2}} E_{1\gamma} \left( \frac{\lambda^2}{2M^2} \right) + 2\lambda e^{-\frac{\lambda^2}{2M^2}} E_{1\gamma} \left( \frac{\lambda^2}{2M^2} \right) + 4M^4 e^{-\frac{\lambda^2}{2M^2}} E_{1\gamma} \left( \frac{\lambda^2}{2M^2} \right). \tag{D.11}
\]

Integrating (D.10) with respect to \( a \) from 0 to \( \Lambda \) yields
\[
\frac{M^2}{8192\pi^4\lambda^2} \left( -2e^{\frac{-\lambda^2}{2M^2}}(\lambda^4 - 2\lambda^2 M^2 + 2M^4)E_{1\gamma} \left( -\frac{\lambda^2}{M^2} \right) + 4\lambda^4 \\
+ 8M^4 \log \left( \frac{\lambda^2}{M^2} \right) + 4\gamma M^4 - 2\lambda^2 M^2 \right). 	ag{D.12}
\]

Summing (D.11) and (D.12), we obtain
\[
\frac{M^2}{2048\pi^4\lambda^2} \left( -e^{\frac{\lambda^2}{2M^2}}(\lambda^4 - 2\lambda^2 M^2 + 2M^4)E_{1\gamma} \left( -\frac{\lambda^2}{M^2} \right) - 5M^2(\lambda^2 + M^2) \right) \\
+ 2M^4 \left( \frac{1}{2} E_{1\gamma} \left( -\frac{\lambda^2}{2M^2} \right) + \log(2) \right) + 5M^4 e^{-\frac{\lambda^2}{2M^2}} - \lambda^2 M^2 e^{-\frac{\lambda^2}{2M^2}} \\
+ \lambda^2 M^2 e^{-\frac{\lambda^2}{2M^2}} E_{1\gamma} \left( \frac{\lambda^2}{2M^2} \right) + 2\lambda e^{-\frac{\lambda^2}{2M^2}} E_{1\gamma} \left( \frac{\lambda^2}{2M^2} \right) + 4M^4 e^{-\frac{\lambda^2}{2M^2}} E_{1\gamma} \left( \frac{\lambda^2}{2M^2} \right) \right). \tag{D.13}
\]

If we expand (D.13) for large \( \lambda \), we get a quadratic divergence as expected:
\[
\frac{M^4}{2048\pi^4\lambda^2} (M^2(\log(4) - 8) - 4\lambda^2). \tag{D.14}
\]

**Appendix E. Dimensional regularization**

If we want to regulate dimensionally an integral, we should follow a certain procedure, see [56–58]. First, we make the following replacement:
\[
\int \frac{d^4k}{(2\pi)^4} g(p, k) h(p, k) \rightarrow \int \frac{d^d k}{(2\pi)^d} g(p, k) h(p, k), \tag{E.1}
\]
as we now wish to perform the integral in \( d \) dimensions, where \( d \) is an arbitrary complex number. Then we express the terms appearing in the denominator \( h(p, k) \) as integrals, using the following relation for positive \( x \):
\[
\frac{1}{x} = \int_0^\infty d\alpha e^{-\alpha x}; \tag{E.2}
\]
\( \alpha \) is called a Schwinger parameter. We complete the square in the exponent of the integrand and then shift the loop momentum variable, so we just have to perform a Gaussian integral. Regarding the numerator \( g(p, k) \), we accordingly shift the loop momentum variable (the integration measure is invariant) in order to be consistent, and drop terms linear in the (shifted) \( k \) as they integrate symmetrically to 0. In the context of dimensional regularization,
we can also make the replacement $k^u k^v \to \frac{\omega^2}{d^2}$, when evaluating the loop integrals (in Euclidean space, after analytic continuation).

For the sake of convenience, let us list the following generalized Gaussian integrals ($a > 0$) in $d$-dimensional Euclidean space, where $d$ is a complex parameter:

\[
\int \frac{d^d k}{(2\pi)^d} \exp\left[-ak^2\right] = \frac{1}{(4\pi a)^{d/2}}.
\]

\[
\int \frac{d^d k}{(2\pi)^d} k_\mu \exp\left[-ak^2\right] = 0,
\]

\[
\int \frac{d^d k}{(2\pi)^d} k_\mu k_\nu \exp\left[-ak^2\right] = \frac{\delta_{\mu\nu}}{2a(4\pi a)^{d/2}},
\]

\[
\int \frac{d^d k}{(2\pi)^d} k^2 \exp\left[-ak^2\right] = \frac{d}{2a(4\pi a)^{d/2}},
\]

\[
\int \frac{d^d k}{(2\pi)^d} k_\mu k_\nu k_\rho \exp\left[-ak^2\right] = 0,
\]

\[
\int \frac{d^d k}{(2\pi)^d} k_\mu k_\nu k_\sigma \exp\left[-ak^2\right] = \frac{\delta_{\mu\nu}\delta_{\rho\sigma} + \delta_{\mu\rho}\delta_{\nu\sigma} + \delta_{\mu\sigma}\delta_{\nu\rho}}{4a^2(4\pi a)^{d/2}},
\]

\[
\int \frac{d^d k}{(2\pi)^d} k^4 \exp\left[-ak^2\right] = \frac{d(d + 2)}{4a^2(4\pi a)^{d/2}},
\]

where $k_\mu$ is a vector in $d$-dimensional Euclidean space. Partial differentiation of (E.3) with respect to $a$ yields the other formulae. All integrals involving odd powers of $k$ vanish.

After the Gaussian integration, there are only some parameter integrals remaining. For instance, if there are two parameter integrals remaining $\int_0^\infty d\alpha_1 \int_0^\infty d\alpha_2$, we can make the following substitutions:

\[
\alpha_1 + \alpha_2 = s, \quad \alpha_1 = s\alpha, \quad \alpha_2 = s(1 - \alpha),
\]

where $0 < s < \infty$ and $0 < \alpha < 1$ while $d\alpha_1 d\alpha_2 = s \, ds \, d\alpha$.

If the integral we are trying to regulate dimensionally is very complicated, we may follow an alternative procedure. We can employ the following relation for the volume element of a $d - 1$-dimensional surface:

\[
d\Omega_d = d\Omega_{d-1}(1 - z^2)^{d-3} \frac{d-3}{2} \, dz,
\]

where $z \equiv \cos(\theta)$ ($\theta$ may be defined to be the angle between $p$ and $k$ in one-loop Feynman integrals with arbitrary external momenta or the angle between $k_1$ and $k_2$ in two-loop Feynman integrals with the external momenta set equal to zero) and $d\Omega_d$ denotes the differential solid angle of the $d$-dimensional unit sphere:

\[
d\Omega_d = \sin^{d-2}(\phi_{d-1}) \sin^{d-3}(\phi_{d-2}) \cdots \sin(\phi_2) \, d\phi_1 \cdots d\phi_{d-1},
\]

where $\phi_i$ is the angle to the $i$th axis, with $0 \leq \phi_i < 2\pi$ and $0 \leq \phi_i < \pi$ for $i > 1$.

Then we can use

\[
\int d^d k = \int d\Omega_d \int_0^{2\pi} k^{d-1} \, dk.
\]
and, subsequently, insert equation \((E.11)\), for which
\[
\Omega_{d-1} = \int d^{d-1}z = \frac{2\pi^{d/2}}{\Gamma\left(\frac{d}{2}\right)}; \tag{E.14}
\]
\(\Gamma(x)\) is the Gamma function.

After all the Gaussian integrals and as many as possible of the parameter integrals have been carried out, we write \(\Omega_{d-1}\) as
\[
\int d^{d-1}z = \frac{2\pi^{d/2}}{\Gamma\left(\frac{d}{2}\right)}
\]
and, then, perform a series expansion in \(\epsilon\) about 0. To make the result dimensionally correct, we may have to multiply it by factors of \(M\), where \(M\) is a mass scale at which the non-local modifications become important. If we get a pole in \(\epsilon\), say \(\frac{1}{\epsilon}\), this means we have a divergence. Otherwise, the integral is finite within the framework of dimensional regularization; this does not necessarily mean that the integral is convergent in the conventional sense.
