Abstract
We deal with a control-affine problem with scalar control subject to bounds, a scalar state constraint and endpoint constraints of equality type. For the numerical solution of this problem, we propose a shooting algorithm and provide a sufficient condition for its local convergence. We exhibit an example that illustrates the theory.

Keywords Optimal control · Shooting algorithm · Singular arc · Second order optimality conditions

Mathematics Subject Classification 49J30 · 49M05 · 49M15

1 Introduction
In this article, we deal with an optimal control problem governed by the dynamics
\[ \dot{x}_t = f_0(x_t) + u_t f_1(x_t) \quad \text{for a.a. } t \in [0, T], \]
subject to the control bounds
\[ u_{\min} \leq u_t \leq u_{\max}, \]
with \( u_{\min} < u_{\max} \), endpoint constraints like

\[ \Phi(x_0, x_T) = 0, \]

and a scalar state constraint of the form

\[ g(x_t) \leq 0. \]

For this class of problems, we propose a shooting-like numerical scheme and we show a sufficient condition for its local quadratic convergence, that is also a second-order sufficient condition for optimality (in a particular sense to be specified later on). Additionally, we solve an example of practical interest, for which we also prove optimality by applying second-order sufficient optimality conditions obtained in Aronna et al. (2016).

This investigation is strongly motivated by applications since we deal with both control and state constraints, which naturally appear in realistic models. Many practical examples that are covered by our chosen framework can be found in the existing literature. A non-exhaustive list includes the prey-predator model (Goh et al. 1974), the Goddard problem in presence of a dynamic pressure limit (Seywald and Cliff 1993; Graichen and Petit 2008), the optimal control of the atmospheric arc for re-entry of a space shuttle seen in Bonnard et al. (2003), an optimal production and maintenance system studied in Maurer et al. (2005), and a recent optimization problem on running strategies (Aftalion and Bonnans 2014). We refer also to de Pinho et al. (2005), Maurer and De Pinho (2014) and Schättler (2006) and references therein.

As it is commonly known, the application of the necessary conditions provided by Pontryagin’s Maximum Principle leads to an associated two-point boundary-value problem (TPBVP) for the optimal trajectory and its associated multiplier (Trélat 2012). A natural way for solving TPBVPs numerically is the application of shooting algorithms (Morrison et al. 1962). This type of algorithms has been used extensively for the resolution of optimal control problems (see e.g. Bulirsch 1971; Bock and Plitt 1984; Pesch 1994 and references therein). In particular, shooting methods have been applied to control-affine problems both with and without state constraints. Some works in this direction are mentioned in the sequel. Maurer (1976) proposed a shooting scheme for solving a problem with bang-singular solutions, which was generalized quite recently by Aronna et al. (2013), where they provided a sufficient condition for its local convergence. Both these articles (Maurer 1976; Aronna et al. 2013) analyze the case with control bounds and no state constraints. Practical control-affine problems with state constraints were solved numerically in several articles, a non-extensive list includes (Maurer and Gillessen 1975; Oberle 1979; Fraser-Andrews 1989) and the recent articles (Cots 2017; Cots et al. 2022). Up to our knowledge, there is no result in the existing literature concerning sufficient conditions for the convergence of shooting algorithms in the framework considered here.

The paper is organized as follows. In Sects. 2 and 2.2 we introduce the problem and give the basic definitions. A shooting-like method and a sufficient condition for its local quadratic convergence are given in Sects. 3 and 4, respectively. The algorithm is implemented in Sect. 5 where we solve numerically a variation of the regulator problem and we prove the optimality of the solution analytically.

**Notations** Let \( \mathbb{R}^k \) denote the \( k \)—dimensional real space, i.e. the space of column real vectors of dimension \( k \), and by \( \mathbb{R}^{k*} \) its corresponding dual space, which consists of \( k \)—dimensional row real vectors. With \( \mathbb{R}_{\leq}^k \) and \( \mathbb{R}_k^+ \) we refer to the subsets of \( \mathbb{R}^k \) consisting of vectors with nonnegative, respectively, nonpositive, components. We write \( h_t \) for the value of function \( h \) at time \( t \) if \( h \) is a function that depends only on \( t \), and by \( h_{i,t} \) the \( i \)th component of \( h \).
evaluated at $t$. Let $h(t+)$ and $h(t−)$ be, respectively, the right and left limits of $h$ at $t$, if they exist. Partial derivatives of a function $h$ of $(t, x)$ are referred as $D_t h$ or $h'$ for the derivative in time, and $D_x h$, $h_x$ or $h''$ for the differentiation with respect to space variables. The same convention is extended to higher order derivatives. By $L^p(0, T)^k$ we mean the Lebesgue space with domain equal to the interval $[0, T] \subset \mathbb{R}$ and with values in $\mathbb{R}^k$. The notations $W^{q,s}(0, T)^k$ and $H^1(0, T)^k$ refer to the Sobolev spaces (see Adams 1975 for further details on Sobolev spaces). We let $BV(0, T)$ be the set of functions with bounded total variation. In general, when there is no place for confusion, we omit the argument $(0, T)$ when referring to a space of functions. For instance, we write $L^\infty$ for $L^\infty(0, T)$, or $(W^{1, \infty})^k$ for the space of $W^{1, \infty}$—functions from $[0, T]$ to $\mathbb{R}^k$. We say that a function $h : \mathbb{R}^k \to \mathbb{R}^d$ is of class $C^\ell$ if it is $\ell$—times continuously differentiable in its domain.

### 2 The problem

Let us consider $L^\infty(0, T)$ and $W^{1, \infty}(0, T; \mathbb{R}^n)$ as control and state spaces, respectively. We say that a control-state pair $(u, x) \in L^\infty(0, T) \times W^{1, \infty}(0, T; \mathbb{R}^n)$ is a trajectory if it satisfies both the state equation

$$\dot{x}_t = f_0(x_t) + u_t f_1(x_t) \quad \text{for a.a.} \ t \in [0, T],$$

and the finitely many endpoint constraints of equality type given by

$$\Phi(x_0, x_T) = 0. \quad (2)$$

Here $f_0$ and $f_1$ are assumed to be Lipschitz continuous and twice continuously differentiable vector fields over $\mathbb{R}^n$, $\Phi$ is of class $C^2$ from $\mathbb{R}^n \times \mathbb{R}^n$ to $\mathbb{R}^q$. Under these hypotheses, for any pair control-initial condition $(u, x_0)$ in $L^\infty(0, T) \times \mathbb{R}^n$, the state equation (1) has a unique solution. Additionally, we consider a cost functional

$$\phi : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R},$$

the control bounds

$$u_{\min} \leq u_t \leq u_{\max} \quad \text{for a.a.} \ t \in [0, T], \quad (3)$$

where $u_{\min} < u_{\max}$, and a scalar state constraint

$$g(x_t) \leq 0 \quad \text{for all} \ t \in [0, T], \quad (4)$$

with the functions $\phi$ and $g : \mathbb{R}^n \to \mathbb{R}$ being of class $C^2$. A trajectory $(u, x)$ is said to be feasible if it satisfies (3) and (4).

**Remark 1** (On the control bounds) We allow $u_{\min}$ and $u_{\max}$ to be either finite real numbers, or to take the values $-\infty$ or $+\infty$, respectively, meaning that we also consider problems with control constraints of the form $u_t \leq u_{\max}$ or $u_{\min} \leq u_t$, as well as problems in the absence of control constraints.

Summarizing, this article deals with the optimal control problem in the Mayer form given by

$$\min \phi(x_0, x_T); \quad \text{subject to} \ (1) - (4). \quad (P)$$
2.1 Types of minima

Throughout this article, we make use of two notions of optimality that are weak and Pontryagin minima and are defined as follows.

Definition 1 (Weak and Pontryagin minima) A weak minimum for (P) is a feasible trajectory \((u,x)\) for which there exists \(\varepsilon > 0\) such that \(\phi(x_0, x_T) \leq \phi(\tilde{x}_0, \tilde{x}_T)\) for any feasible \((\tilde{u}, \tilde{x})\) verifying \(\|\tilde{u} - u\|_\infty < \varepsilon\).

A feasible trajectory \((u,x)\) is called a Pontryagin minimum for (P) if for any \(M > 0\), there exists \(\varepsilon_M > 0\) such that \(\phi(x_0, x_T) \leq \phi(\tilde{x}_0, \tilde{x}_T)\) for any feasible \((\tilde{u}, \tilde{x})\) satisfying

\[
\|\tilde{x} - x\|_\infty + \|\tilde{u} - u\|_1 < \varepsilon_M, \quad \|\tilde{u} - u\|_\infty < M. \tag{5}
\]

Note that any Pontryagin minimum is also a weak minimum. Consequently, necessary conditions that hold for weak minima, also do it for Pontryagin one. This article provides a numerical scheme for approximating Pontryagin minima of (P). In order to achieve this, we make use of the auxiliary unconstrained transformed problem (TP) given in equations (14)–(22), which possesses neither control bounds nor state constraints and can be solved numerically in an efficient way. In Lemma 1 below we prove that transformed Pontryagin minima of (P) that verify certain structural hypotheses are weak minima of the unconstrained transformed problem (TP).

2.2 Bang, constrained and singular arcs

The contact set associated with the state constraint is defined as

\[
C := \{t \in [0,T]: g(\hat{x}_t) = 0\}. \tag{6}
\]

For \(0 \leq a < b \leq T\), we say that \((a,b)\) is an active arc for the state constraint or, shortly, a C arc, if \((a,b)\) is a maximal open interval contained in \(C\). A point \(\tau \in (0,T)\) is a junction point of the state constraint if it is the extreme point of a C arc.

Similar definitions hold for the control constraint, with the difference that the control variable is only almost everywhere defined. The contact sets for the control bounds are given by

\[
B_- := \{t \in [0,T]: \hat{u}_t = u_{\min}\}, \quad B_+ := \{t \in [0,T]: \hat{u}_t = u_{\max}\},
\]

\[
B := B_- \cup B_+.
\]

Note that these sets are defined up to null measure sets. Additionally, observe that if \(u_{\min} = -\infty\) then \(B_- = \emptyset\) and, analogously, if \(u_{\max} = +\infty\) then \(B_+ = \emptyset\). We say that \((a,b)\) is a \(B_-\) (resp. \(B_+\)) arc if \((a,b)\) is included, up to a null measure set, in \(B_-\) (resp. in \(B_+\)), but no open interval strictly containing \((a,b)\) is. We say that \((a,b)\) is a B arc if it is either a \(B_-\) or a \(B_+\) arc.

Finally, let \(S\) denote the singular set given by

\[
S := \{t \in [0,T]: u_{\min} < \hat{u}_t < u_{\max} \text{ and } g(\hat{x}_t) < 0\}. \tag{7}
\]

We say that \((a,b)\) is an S arc if \((a,b)\) is included, up to a null measure set, in \(S\), but no open interval strictly containing \((a,b)\) is.

We call junction or switching times the points \(\tau \in (0,T)\) at which the trajectory \((\hat{x}, \hat{u})\) switches from one type of arc \((B_-, B_+, C\) or \(S\)) to another type. Junction/switching times
are denominated by the type of arcs they separate. One can have, for instance, *CS junction, B−B+ switching time, etc.*

Throughout the remainder of the article, we assume that the *state constraint is of first order*, this is,

\[ g'(\hat{x}_t) f_1(\hat{x}_t) \neq 0 \text{ on } C, \]  

and we impose the following *hypotheses on the control structure*:

- (i) the interval \([0, T]\) is (up to a zero measure set) the disjoint union of finitely many arcs of type \(B, C\) and \(S\), and the set \(C\) does not contain isolated points,
- (ii) the control \(\hat{u}\) is at uniformly positive distance of the bounds \(u_{\text{min}}\) and \(u_{\text{max}}\), over \(C\) and \(S\) arcs,
- (iii) the control \(\hat{u}\) is discontinuous at CS and SC junctions.

**Remark 2** Note that some problems [even if they are convex, like Fuller’s problem (Fuller 1963)] exhibit chattering phenomena with infinitely many switches, necessarily with some very short arcs. It is not clear how to deal with such problems with the method that we present in this article.

The example of the regulator problem studied in Sect. 5 fulfills the above hypothesis (9) [see as well the example given in Aronna et al. (2016, Remark 2)].

When a control satisfying hypothesis (9)(i) is, for instance, a concatenation of a bang and a singular arc, we call it a *BS control*. This denomination is extended for any finite sequence of arc types.

In order to formulate our shooting algorithm, we express the control as a function of the state on \(C\) arcs and we fix the control to its bounds on \(B\) arcs.

### 2.2.1 Expression of the control on constrained arcs

From \(g(\hat{x}_t) = 0\) on \(C\), we get

\[ 0 = \frac{d}{dt} g(\hat{x}_t) = g'(\hat{x}_t) \left( f_0(\hat{x}_t) + \hat{u}_t f_1(\hat{x}_t) \right) \text{ on } C, \]  

and, since (8) holds, we have that

\[ \hat{u}_t = -\frac{g'(\hat{x}_t) f_0(\hat{x}_t)}{g'(\hat{x}_t) f_1(\hat{x}_t)} \text{ on } C. \]  

### 3 Shooting formulation

We now explain how to state a transformed problem with neither control bounds nor running state constraints that serves as an intermediate step to write a numerical scheme for problem \((P)\). Afterwards the optimality system of the transformed problem is reduced to a nonlinear equation in a finite dimensional space.

The starting point is to estimate the arc structure of the control, i.e. the sequence of its different types of arcs and the approximate values of its junction times. This is done in practice by some *direct method* such as solving the nonlinear programming (NLP) associated to the
discretization of the optimal control problem. Then we formulate a transformed problem in which the control is fixed to its bounds on B arcs, and is expressed as a function of the state on C arcs. So the optimization variables are now the control over singular arcs and the switching times. Subsequently, we express the optimality conditions of the transformed problem. Finally, by eliminating the control as a function of the state and costate, we reduce the optimality system to a finite dimensional equation.

So, let us assume for the remainder of the section that \((\hat{u}, \hat{x})\) is a Pontryagin minimum for \((P)\). Additionally, without loss of generality and for the sake of simplicity of notation, we set \(u_{\text{min}} := 0\) and \(u_{\text{max}} := 1\). Recall further that \((\hat{u}, \hat{x})\) complies with the structural hypotheses (9) for the control \(\hat{u}\), and that the state constraint is of first order, i.e. (8) holds true.

### 3.1 The transformed problem

We now state the transformed problem corresponding to \((P)\), in the spirit of Aronna et al. (2013), and we prove that any Pontryagin minimum for the original problem \((P)\) is transformed into a weak minimum of the unconstrained transformed problem.

For the Pontryagin minimum \((\hat{u}, \hat{x})\), let

\[
0 =: \hat{t}_0 < \hat{t}_1 < \cdots < \hat{t}_N := T
\]

denote its associated switching times. Recall the definition of the sets \(C\), \(B_-\), \(B_+\) and \(S\) given in Sect. 2.2 above. Set \(\hat{I}_k := [\hat{t}_{k-1}, \hat{t}_k]\) for \(k = 1, \ldots, N\), and

\[
\mathcal{I}(S) := \{k \in \{1, \ldots, N\} : \hat{I}_k \text{ is a singular arc}\}.
\]

Analogously, define \(\mathcal{I}(C)\), \(\mathcal{I}(B_-)\), and \(\mathcal{I}(B_+)\). For each \(k = 1, \ldots, N\), consider a state variable \(x^k \in W^{1,\infty}(0, T; \mathbb{R}^n)\), and for each singular arc \(k \in \mathcal{I}(S)\), a control variable \(u^k \in L^\infty(0, T)\). On the set \(B\), we fix the control to the corresponding bound. Additionally, recall that from formula (11) we have that \(\hat{u}_t = \Gamma(\hat{x}_t)\) on \(C\), where \(\Gamma\) is given by

\[
\Gamma(x) := \frac{g'(x)f_0(x)}{g'(x)f_1(x)}.
\]

After these considerations, we are ready to state the transformed problem. Define the optimal control problem \((\text{TP})\), on the time interval \([0, 1]\), by

\[
\begin{align*}
\min \phi(x_0^1, x_1^N), \\
\dot{x}^k &= (\tau_k - \tau_{k-1}) \left( f_0(x^k) + u^k f_1(x^k) \right) \quad \text{for } k \in \mathcal{I}(S), \\
\dot{x}^k &= (\tau_k - \tau_{k-1}) f_0(x^k) \quad \text{for } k \in \mathcal{I}(B_-), \\
\dot{x}^k &= (\tau_k - \tau_{k-1}) \left( f_0(x^k) + f_1(x^k) \right) \quad \text{for } k \in \mathcal{I}(B_+), \\
\dot{x}^k &= (\tau_k - \tau_{k-1}) \left( f_0(x^k) + \Gamma(x^k) f_1(x^k) \right) \quad \text{for } k \in \mathcal{I}(C), \\
\dot{t}_k &= 0 \quad \text{for } k = 1, \ldots, N - 1, \\
\Phi(x_0^1, x_1^N) &= 0, \\
g(x_0^k) &= 0 \quad \text{for } k \in \mathcal{I}(C), \\
x_1^k &= x_0^{k+1} \quad \text{for } k = 1, \ldots, N - 1.
\end{align*}
\]

**Remark 3** Since we use the expression (11) to eliminate the control from the expression (10) of the derivative of the state constraint equal to zero, we impose the entry conditions (21) in
the formulation of (TP) in order to guarantee that the state constraint is active along \( x^k \) for every \( k \in \mathcal{I}(C) \).

Set
\[
\hat{x}_s^k := \hat{x}(\hat{t}_{k-1} + (\hat{t}_k - \hat{t}_{k-1})s) \quad \text{for } s \in [0, 1] \text{ and } k = 1, \ldots, N, \\
\hat{u}_s^k := \hat{u}(\hat{t}_{k-1} + (\hat{t}_k - \hat{t}_{k-1})s) \quad \text{for } s \in [0, 1] \text{ and } k \in \mathcal{I}(S).
\] (23)

**Lemma 1** Let \((\hat{u}, \hat{x})\) be a Pontryagin minimum of problem (P). Then the triple
\[
\left( (\hat{u}^k)_{k \in \mathcal{I}(S)}, (\hat{x}^k)_{k=1}^N, (\hat{\tau}_k)_{k=1}^{N-1} \right)
\]
is a weak solution of (TP).

**Proof** Consider the feasible trajectories \((u^k, (x^k), (\tau_k))\) for (TP) satisfying
\[
\|u^k - \hat{u}^k\|_{\infty} < \bar{\varepsilon} \quad \text{and} \quad |\tau_k - \hat{\tau}_k| \leq \bar{\delta} \quad \text{for all } k = 1, \ldots, N,
\] (24)
for some \( \bar{\varepsilon}, \bar{\delta} > 0 \) to be determined later. Set \( I_k := [\tau_{k-1}, \tau_k] \) and consider the functions \( s_k : I_k \to [0, 1] \) given by \( s_{k,t} := \frac{t - \tau_{k-1}}{\tau_k - \tau_{k-1}} \). Define \( u : [0, T] \to \mathbb{R} \) by
\[
u_t := \begin{cases} 0 & \text{if } t \in I_k, \ k \in \mathcal{I}(B_-), \\ 1 & \text{if } t \in I_k, \ k \in \mathcal{I}(B_+), \\ \Gamma(x^k(s_{k,t})) & \text{if } t \in [0, 1], \ \text{a.a. } t \in I_k, \\ u^k(s_{k,t}) & \text{if } t \in I_k, \ k \in \mathcal{I}(S). 
\end{cases}
\] (25)

Let \( x : [0, T] \to \mathbb{R}^n \) be the state corresponding to the control \( u \) and the initial condition \( x(0) = x_0^1 \).

We next show that if \( \bar{\varepsilon} > 0 \) and \( \bar{\delta} > 0 \) are small enough, then \( (u, x) \) is feasible for (P) and arbitrarily close to \((\hat{u}, \hat{x})\) in the sense of (5). Observe that \( x(t) = x^k(s_{k,t}) \) for all \( k = 1, \ldots, N \) and \( t \in I_k \). Hence, \( x \) satisfies the endpoint constraints. Furthermore, due to Gronwall’s Lemma, \((u, x)\) verifies the estimate
\[
\|u - \hat{u}\| + \|x - \hat{x}\|_{\infty} < O(\bar{\varepsilon} + \bar{\delta}).
\] (26)

Let us analyze the control constraints. Take \( k = 1, \ldots, N \). If \( k \in \mathcal{I}(B_-) \cup \mathcal{I}(B_+) \), then \( u_t \in \{0, 1\} \) for a.a. \( t \in I_k \). On the other hand, by the hypothesis (9) on the control structure, there exists \( \rho_1 > 0 \) such that
\[
\rho_1 < \hat{u}_t < 1 - \rho_1 \quad \text{over } C \text{ and } S \text{ arcs.}
\] (27)

Suppose now that \( k \in \mathcal{I}(S) \). Then, in view of (24) and (27), we can see that the control constraints hold on \( I_k \) provided that \( \bar{\varepsilon} \leq \rho_1 \). Finally, let \( k \) be in \( \mathcal{I}(C) \). Notice that in this case (27) is equivalent to
\[
\rho_1 < \Gamma(\hat{x}_t) < 1 - \rho_1 \quad \text{on } \hat{I}_k.
\] (28)

Hence, by standard continuity arguments and for \( \bar{\varepsilon}, \bar{\delta} \) sufficiently small, we get that
\[
0 < \Gamma(x(t)) < 1 \quad \text{on } I_k.
\] (29)

We therefore confirm that \((u, x)\) verifies the control constraints.

Let us now consider the state constraint. Take first \( k \in \mathcal{I}(C) \). Then \( g(x_{\tau_k}) = g(x^k_{\tau_k}) = 0 \) and, by definition of \((u, x)\), we have that \( \frac{\partial}{\partial t}g(x(t)) = 0 \) for all \( t \in I_k \). Therefore, \( x \) satisfies
the state constraint on $I_k$ for $k \in \mathcal{I}(C)$. Next, observe that, due to (9), for any $t \in [0, T]$ sufficiently far from a $C$ arc, one has $g(\hat{x}_t) \leq -\rho$ for some small $\rho > 0$. Thus, by (26) we get that $g(x_t) < 0$ for appropriate $\tilde{\epsilon}, \tilde{\delta}$. On the other hand, for $t \in [0, T]$ close to a $C$ arc, we reason as follows. Assume, without loss of generality, that $t$ is near an entry point $\tau_k$ of a $C$ arc. In view of hypothesis (9) and of the relation (10), we have that $\frac{d}{dt}|_{s=\tau_k - g(\hat{x}_s)} > 0$, therefore, $\frac{d}{dt}|_{s=\tau_k - g(x_s)} > 0$ as well, if $\tilde{\epsilon}, \tilde{\delta}$ are sufficiently small. Consequently, $g(x_t) < 0$. Hence, $x$ verifies the state constraint on $[0, T]$. With this, we conclude that $(u, x)$ is feasible for the original problem (P).

Finally, given $M > 0$ as in Definition 1, we can easily show that $\tilde{\delta}$ and $\tilde{\epsilon}$ can be taken in such a way that $(u, x)$ satisfies (5) for such $M$ and the corresponding $\varepsilon_M$ provided by the Pontryagin optimality of $(\hat{u}, \hat{x})$. Consequently, $\phi(x_0, x_1) \geq \phi(\hat{x}_0, \hat{x}_1)$ or, equivalently,

$$\phi(x_0^1, x_1^1) \geq \phi(\hat{x}_0^1, \hat{x}_1^1),$$

which proves that $((\hat{u}^k)_{k \in \mathcal{I}(S)}, (\hat{x}^k)_{k=1}^N, (\hat{\tau}^k)_{k=1}^{N-1})$ is a weak solution of (TP), as desired. This concludes the proof.

3.2 The shooting function

We shall start by rewriting the problem (TP) in the following compact form, in order to ease the notation,

$$\min \hat{\phi}(X_0, X_1),$$

$$\hat{X} = \hat{f}_0(X) + \sum_{k \in \mathcal{I}(S)} U^k \hat{f}_k(X),$$

$$\hat{\Phi}(X_0, X_1) = 0,$$

where $X := (x_k^N)_{k=1}^N, (\tau_k)_{k=1}^{N-1})$, $U := (u^k)_{k \in \mathcal{I}(S)}$, the vector field $\hat{f}_0 : \mathbb{R}^{Nn+N-1} \to \mathbb{R}^{Nn+N-1}$ is defined as follows,

$$(\hat{f}_0(X))_{i=(k-1)n+1}^{kn} := \begin{cases} (\tau_k - \tau_{k-1})f_0(x_k) & \text{for } k \in \mathcal{I}(S) \cup \mathcal{I}(B_-), \\ (\tau_k - \tau_{k-1})f_0(x_k) + f_1(x_k) & \text{for } k \in \mathcal{I}(B_+), \\ (\tau_k - \tau_{k-1})(f_0(x_k) + \Gamma(x_k) f_1(x_k)) & \text{for } k \in \mathcal{I}(C), \end{cases}$$

and $((\hat{f}_0(X))_{i=(k-1)n+1}^{Nn+N-1})_{i=nN+1}^{nN+1} := 0$. Additionally, for $k \in \mathcal{I}(S)$ the vector field $\hat{f}_k : \mathbb{R}^{Nn+N-1} \to \mathbb{R}^{Nn+N-1}$ is given by

$$(\hat{f}_k(X))_{i=(k-1)n+1}^{kn} := (\tau_k - \tau_{k-1})f_1(x_k),$$

and $((\hat{f}_k(X))_{i=0}^{(k-1)n+1}) := 0$ for the remaining index $i$, the new cost $\hat{\phi} : \mathbb{R}^{2(Nn+N-1)} \to \mathbb{R}$ is

$$\hat{\phi}(X_0, X_1) := \phi(x_0^1, x_1^N),$$

and the function $\hat{\Phi} : \mathbb{R}^{2(Nn+N-1)} \to \mathbb{R}^{d\phi}$ with $d\phi := q + (\mathcal{I}(C)) + n(N - 1)$ is defined as

$$\hat{\Phi}(X_0, X_1) := \begin{pmatrix} \Phi(x_0^1, x_1^N) \\ (g(x_0^k))_{k \in \mathcal{I}(C)} \\ (x_k - x_0^{k+1})_{k=1}^{N-1} \end{pmatrix}.$$
The pre-Hamiltonian for problem (TP) is given by
\[
\tilde{\mathcal{H}} = P \left( f_0(X) + \sum_{k \in \mathcal{I}(S)} U^k \tilde{f}_k(X) \right) = \sum_{k=1}^N (\tau_k - \tau_{k-1}) H^k, \tag{34}
\]
where \( P \) denotes the costate associated to (TP),
\[
H^k := p^k (f_0(x^k) + w^k f_1(x^k)), \tag{35}
\]
with the notation \( w^k \) defined as
\[
\begin{cases}
  u^k & \text{if } k \in \mathcal{I}(S), \\
  0 & \text{if } k \in \mathcal{I}(B_-), \\
  1 & \text{if } k \in \mathcal{I}(B_+), \\
  \Gamma(x^k) & \text{if } k \in \mathcal{I}(C),
\end{cases} \tag{36}
\]
and \( p^k \) denotes the \( n \)-dimensional vector of components \( p_{(k-1)n+1}, \ldots, p_{kn} \). Note that \( w^k \) is a variable only for \( k \in \mathcal{I}(S) \), in which case it represents the control \( u^k \).

### 3.3 Constraint qualification and first-order optimality condition for (TP)

Since problem (TP) has only endpoint equality constraints, and the Hamiltonian is an affine function of the control, it is known that Pontryagin’s Maximum Principle is equivalent to the first-order optimality conditions. So, the qualification condition is that the derivative of the constraint is onto at the nominal trajectory \((\hat{U}, \hat{X})\), see e.g. Bonnans and Shapiro (2000, Ch. 3). This means that
\[
\Phi : \mathbb{R}^{Nn+N-1} \times (L^\infty)^{|\mathcal{I}(S)|} \to \mathbb{R}^d, \quad (X_0, U) \mapsto \Phi(X_0, X_1), \tag{37}
\]
where \( X_t \) is the solution of (32) associated to \((X_0, U)\) is such that
\[
D\Phi(\hat{X}_0, \hat{U}) \text{ is surjective.} \tag{38}
\]
Under this hypothesis, the first-order optimality condition in normal form is as follows, defining the endpoint Lagrangian associated to (TP) by:
\[
\tilde{\ell} := \phi(x_0^1, x_1^N) + \sum_{j=1}^q \Psi_j \Phi_j(x_0^1, x_1^N) + \sum_{k \in \mathcal{I}(C)} \gamma_k g(x_0^k) + \sum_{k=1}^{N-1} \theta_k (x_k^1 - x_0^{k+1}). \tag{39}
\]

**Theorem 2** Let \((\hat{U}, \hat{X})\) be a weak solution for (TP) satisfying the qualification condition (38). Then there exists a unique \( \tilde{\lambda} := (\tilde{\Psi}, P) \in \mathbb{R}^{d\Phi^*} \times (W^{1,\infty})^{Nn+N-1*} \) such that \( P \) is solution of
\[
-\dot{P}_t = D_X \tilde{\mathcal{H}}(\hat{U}_t, \hat{X}_t, P_t) \text{ a.e. on } [0, T], \tag{40}
\]
with transversality conditions
\[
P_0 = -D_{X_0} \tilde{\ell}(\hat{X}_0, \hat{X}_1), \tag{41}
\]
and with
\[
\tilde{H}_U(\hat{U}_t, \hat{X}_t, P_t) = 0. \tag{42}
\]
Proof} This is a variant of Bonnans (2019, Theorem 1.174), where the cost function was supposed to be convex: one easily checks that the proof is essentially the same if the cost is differentiable. See also Arutyunov and Karamzin (2020).

Since there is a unique associated multiplier, we omit from now on the dependence on \( \tilde{\lambda} \) for the sake of simplicity of the presentation. Moreover, in some occasions, we omit the dependence on the nominal solution \((\tilde{U}, \tilde{X})\).

### 3.4 Expression of the singular controls in problem (TP)

It is known that in this control-affine case, the control variable does not appear explicitly neither in the expression of \( \tilde{H}_U \) nor in its time derivative \( \dot{\tilde{H}}_U \) (see e.g. Robbins 1967; Aronna et al. 2013). The \textit{strengthened generalized Legendre–Clebsch condition} (Robbins 1967) for (TP) reads

\[
- \frac{\partial}{\partial U} \dot{\tilde{H}}_U > 0. \tag{43}
\]

Here \( A > B \), where \( A \) and \( B \) are symmetric matrices of same size, means that \( A - B \) is positive semidefinite. At this point, recall the definitions of \( H^k \) and \( p^k \) given in (35) and in the first line after (36), respectively. Simple calculations show that the l.h.s. of (43) is a \(|\mathcal{I}(S)| \times |\mathcal{I}(S)|\)-diagonal matrix with positive entries equal to

\[
-(\tau_k - \tau_{k-1}) \frac{\partial}{\partial u^k} \dot{H}^k_{u^k} \quad \text{for } k \in \mathcal{I}(S). \tag{44}
\]

Then condition (43) becomes

\[
\frac{\partial}{\partial u^k} \dot{H}^k_{u^k} < 0 \quad \text{for } k \in \mathcal{I}(S). \tag{45}
\]

Hence, thanks to (45), for each \( k \in \mathcal{I}(S) \) one can compute the control \( u^k \) from the identity

\[
\dot{H}^k_{u^k} = 0. \tag{46}
\]

Apart from the previous equation (46), in order to ensure the stationarity \( H^k_{u^k} = 0 \), we add the following endpoint conditions:

\[
0 = H^k_{u^k}(0) = p^k_0 f_1(x^k_0), \quad 0 = \dot{H}^k_{u^k}(0) = p^k_0 [f_1, f_0](x^k_0) \quad \text{for } k \in \mathcal{I}(S). \tag{47}
\]

### 3.5 Lagrangians and costate equation

The costate equation for \( p^k \) is

\[
p^k = -(\tau_k - \tau_{k+1}) D_{x^k} H^k, \tag{48}
\]

with endpoint conditions

\[
p^1_0 = -D_{x^1_0} \tilde{\ell} = -D_{x^1_0} \phi - \sum_{j=1}^q \Psi_j D_{\psi_j} \phi_j - \chi_{\mathcal{I}(C)}(1) g'(x^1_0), \tag{49}
\]

\[
p^k_1 = \theta^k \quad \text{for } k = 1, \ldots, N - 1, \tag{50}
\]

\[
p^k_0 = \theta^{k-1} - \chi_{\mathcal{I}(C)}(k) g'(x^k_0) \quad \text{for } k = 2, \ldots, N, \tag{51}
\]
where \( \chi_{I(C)} \) denotes the \textit{characteristic function} associated to the set \( I(C) \). For the costate \( p^\tau_k \) we have the dynamics

\[
\dot{p}^\tau_k = -H^k + H^{k+1}, \quad p_0^\tau = 0, \quad p_1^\tau = 0 \quad \text{for } k = 1, \ldots, N - 1.
\]  

It is known that the pre-Hamiltonian of autonomous problems has a constant value along an optimal solution (see e.g. Trélat 2012). By similar arguments it is easily seen that each \( H^k \) is a constant function of time along an optimal solution. Consequently, from (53) we get that \( p^\tau_k \) vanishes identically and that

\[
H^k_1 = H^k_0 + 1 \quad \text{for } k = 1, \ldots, N - 1.
\]  

### 3.6 The shooting function and method

The shooting function associated with (TP) that we propose here is

\[
S : \mathbb{R}^{Nn+N−1} \times \mathbb{R}^{Nn+q+|I(C)|,*} \to \mathbb{R}^{(N−1)n+N−1+q+|I(C)|+2|I(S)|} \times \mathbb{R}^{(N+1)n,*},
\]

\[
((x^k_0), (\tau_k), (p^k_0), \Psi, \gamma) \mapsto \begin{pmatrix}
\Phi(x^1_0, x^N_1) \\
g(x^k_0) \\
(x^k_1 - x^{k+1}_0)_{k=1,\ldots,N-1} \\
p_0^1 + D_{x^1_0} \ell/\Psi \\
p^k_0 + n^k_0 - \chi_{I(C)}(k) n^k g'(x^k_0) \\
p^g - D_{x^N_1} \ell/\Psi \\
(H^k_1 - H^k_0 + 1)_{k=1,\ldots,N-1} \\
p^k_0 f_1(x^k_0)_{k \in I(S)} \\
p^k_0 [f_1, f_0](x^k_0)_{k \in I(S)}
\end{pmatrix},
\]  

where \( ((x^k), (p^k), (u^k)) \) is the solution of the state and costate equations (15)–(18), (48) with initial values \( (x^0_0), (p^0_0) \), and control \( (u^k)_{k \in I(S)} \), given by the stationarity condition (46). Note that we removed the variable \( \theta \) by combining equations (50) and (51).

The key feature of this procedure is that \( \omega := ((x^k_0), (\tau_k), (p^k_0), \Psi, \gamma) \) satisfies

\[
S(\omega) = 0,
\]  

if and only if the associated solution \( ((x^k), (p^k), (u^k)) \) verifies the Pontryagin’s Maximum Principle for (TP). Briefly speaking, in order to find the candidate solutions of (TP), we shall solve (56).

Let us observe that the system (56) has \( 2Nn + N - 1 + q + |I(C)| \) unknowns and \( 2Nn + N - 1 + q + |I(C)| + 2|I(S)| \) equations. Hence, as soon as a singular arc occurs, (56) has more equations than unknowns, i.e. it is overdetermined. We then follow (Aronna et al. 2013), where the authors suggested to solve the shooting equations by the Gauss–Newton method. We recall the following convergence result for Gauss–Newton, see e.g. Fletcher (2013), or alternatively Bonnans et al. (2006). If \( F \) is a \( C^1 \) mapping from \( \mathbb{R}^n \) to \( \mathbb{R}^p \) with \( p > n \), the Gauss–Newton method computes a sequence \( (y^j) \) in \( \mathbb{R}^n \) satisfying
\[ F(y^j) + DF(y^j)(y^{j+1} - y^j) = 0. \] When \( F \) has a zero at \( \bar{y} \) and \( DF(\bar{y}) \) is onto, the sequence \((y^j)\) is well-defined provided that the starting point \( y^0 \) is close enough to \( \bar{y} \) and in that case, \((y^j)\) converges superlinearly to \( \bar{y} \) (quadratically if \( DF \) is Lipschitz near \( \bar{y} \)). In view of the regularity hypotheses done in Sect. 2, we know that \( S' \) is Lipschitz continuous.

### 4 Sufficient condition for the convergence of the shooting algorithm

The main result of this article is Theorem 6 of current section. It gives a sufficient condition for the local convergence of the shooting algorithm, that is also a sufficient condition for weak optimality of problem (TP), as stated in Theorem 5 below.

#### 4.1 Second-order optimality conditions for (TP)

We now recall some second-order optimality conditions for (TP). Let us consider the quadratic mapping on the space \( (L^\infty)^{|\mathcal{Z}(S)|} \times (W^{1,\infty})^{n+n-1} \), defined as

\[
\tilde{Q}(V, Z) := \frac{1}{2} D^2\tilde{\ell}(Z_0, Z_1)^2 + \frac{1}{2} \int_0^1 [Z^\top \tilde{H}_{XX} Z + 2V \tilde{H}_{UX} Z] dt. \tag{57}
\]

We next introduce the critical cone associated to (TP). Since the problem has only qualified equality constraints, this critical cone coincides with the tangent space to the constraints. Consider first the linearized state equation

\[
\dot{Z} = \tilde{A}Z + \tilde{B}V \quad \text{a.e. on } [0, 1], \tag{58}
\]

where \( F(U, X) := \tilde{f}_0(X) + \sum_{k \in \mathcal{Z}(S)} U_k \tilde{f}_k(X) \), \( \tilde{A} := F_X \), \( \tilde{B} := FU \); and let the linearization of the endpoint constraints be given by

\[
D\tilde{\Phi}(Z_0, Z_1) = 0. \tag{59}
\]

The critical cone for (TP) is defined as

\[
\tilde{C} := \{ (V, Z) \in (L^\infty)^{|\mathcal{Z}(S)|} \times (W^{1,\infty})^{n+n-1} : (58)-(59) \text{ hold} \}. \tag{60}
\]

The following result follows (see e.g. Levitin et al. 1978; Aronna et al. 2012 for a proof).

**Theorem 3** (Second-order necessary condition) *If \((\hat{U}, \hat{X})\) is a weak minimum for (TP) that verifies (38), then

\[
\tilde{Q}(V, Z) \geq 0 \quad \text{for all } (V, Z) \in \tilde{C}. \tag{61}
\]

In the sequel we present some optimality conditions for (TP). The first one is a necessary condition due to Goh (1966a) and the second one, a sufficient condition from Dmitruk (1977, 1987). The idea behind these results lies on the following observation. Note that \( \tilde{H}_{UU} \) vanishes and, therefore, the quadratic mapping \( \tilde{Q} \) does not contain a quadratic term on the control variation \( V \). Consequently, the Legendre-Clebsch necessary optimality condition on the positive semidefiniteness of \( \tilde{H}_{UU} \) holds trivially and a second-order sufficient condition cannot be obtained by strengthening inequality (61). In order to overcome this issue and derive necessary conditions for this singular case, Goh introduced a change of variables in Goh (1966b) and applied it to derive necessary conditions in Goh (1966a). Some years later, Dmitruk (1977) showed a second-order sufficient condition in terms of the coercivity of the transformation \( \tilde{\Omega} \) of \( \tilde{Q} \) introduced below.
The Goh transformation for the linear system $(58)$ is given by

$$ Y_t := \int_0^t V_s ds, \quad \Xi_t := Z_t - \tilde{B}_t Y_t. \quad (62) $$

Notice that if $(V, Z) \in \tilde{C}$, then $(Y, \Xi)$ defined by the above transformation $(62)$ satisfies (removing time indexes):

$$ \dot{\Xi} = AZ + \tilde{B}U - \tilde{B}U - \dot{\tilde{B}}Y = A(\Xi + \tilde{B}Y) - \dot{\tilde{B}}Y, \quad (63) $$

and, therefore $\Xi$ is solution of the transformed linearized equation

$$ \dot{\Xi} = \tilde{A}\Xi + \tilde{E}Y, \quad (64) $$

where $\tilde{E} := \tilde{A}\tilde{B} - \frac{d}{dt} \tilde{B}$, and $\Xi$ satisfies the transformed linearized endpoint constraints

$$ D\tilde{\Phi}(\Xi_0, \Xi_1 + \tilde{B}_1 h) = 0, \quad (65) $$

where we set $h := Y_1$.

Consider the function

$$ \rho(\zeta_0, \zeta_1, h) := D^2\tilde{\ell}(\zeta_0, \zeta_1 + \tilde{B}_1 h)^2 + h\tilde{H}_{UU,1}(2\zeta_1 + \tilde{B}_1 h), \quad (66) $$

and the quadratic mapping

$$ \tilde{\Omega}(Y, \tilde{h}, \Xi) := \frac{1}{2} \rho(\Xi_0, \Xi_1, \tilde{h}) + \frac{1}{2} \int_0^1 \left( \Xi^T \tilde{H}_{XX} \Xi + 2Y\tilde{M} \Xi + Y\tilde{R}Y \right) dt, \quad (67) $$

for $(Y, \tilde{h}, \Xi) \in (L^2)^{|\mathcal{I}(S)|} \times \mathbb{R} \times (H^1)^{N+n+N-1}$ and

$$ \tilde{M} := f_1^T \tilde{H}_{XX} - \frac{d}{dt} \tilde{H}_{UX} - \tilde{H}_{UX} \tilde{A}, \quad \tilde{R} := f_1^T \tilde{H}_{XX} f_1 - 2\tilde{H}_{UX} \tilde{E} - \frac{d}{dt}(\tilde{H}_{UX} f_1). \quad (68) $$

Let us recall that the second-order necessary condition for optimality stated by Goh (1966a) (and nowadays known as Goh condition) implies that if $(\tilde{U}, \tilde{X})$ is a weak minimum for (TP) verifying $(38)$, then

$$ \tilde{H}_{UX} \tilde{B} \text{ is symmetric}, \quad (69) $$

or, equivalently, $P \cdot D\tilde{f}_i \tilde{f}_j = P \cdot D\tilde{f}_j \tilde{f}_i$ for all $i, j = 1, \ldots, N$. In the recent literature, this condition can be encountered as $P \cdot [\tilde{f}_i, \tilde{f}_j] = 0$. We shall mention that this necessary condition was first stated by Goh (1966a) for the case with neither control nor state constraints, and extended in Aronna et al. (2012); Frankowska and Tonon (2013) for problems containing control constraints.

Notice that when the control variable of (TP) is scalar (i.e. $|\mathcal{I}(S)| = 1$), then $(69)$ is trivially verified since $\tilde{H}_{UX} \tilde{B}$ is also a scalar.

We claim that $(D\tilde{f}_i) f_j = 0$, for all $i, j \in \{1, \ldots, N\}$ with $i \neq j$ and, consequently, the matrix in $(68)$ is diagonal and the Goh condition holds trivially for (TP) even when $|\mathcal{I}(S)| > 1$. Indeed, let $k, \ell$ be disjoint elements of $\mathcal{I}(S)$. By the definition, the nonzero components of $\tilde{f}_k(X)$ have coordinates in the set $I_k := \{(k-1)n + 1, kn\}$. So, only the rows of $D\tilde{f}_k(X)$ in $I_k$ can be nonzero. However, since $I_k \cap I_\ell$ is empty, $\tilde{f}_k$ has only zero components in $I_\ell$. Our claim follows.

From $(69)$ and Aronna et al. (2012, Theorem 4.4) we get the following result:
Proposition 4 For all \((V, Z) \in (L^\infty)^{|\mathcal{I}(S)|} \times (W^{1,\infty})^{Nn+N-1}\) solution of (58) and \((Y, \Xi)\) given by the Goh transform (62), it holds
\[
\tilde{Q}(V, Z) = \tilde{\Omega}(Y, Y_T, \Xi).
\]
Define, for \((\Xi_0, Y, \tilde{h}) \in \mathbb{R}^n \times (L^2)^{|\mathcal{I}(S)|} \times \mathbb{R}\), the order function
\[
\gamma(\Xi_0, Y, \tilde{h}) := |\Xi_0|^2 + \int_0^1 |Y_t|^2 dt + |\tilde{h}|^2.
\] (70)

Definition 2 \((\gamma\text{-growth})\) A feasible trajectory \((\hat{U}, \hat{X})\) of (TP) satisfies the \(\gamma\)-growth condition in the weak sense if there exists a positive constant \(c\) such that, for every sequence of feasible variations \(\{\delta X_k^0, V_k\}\) converging to 0 in \(\mathbb{R}^{Nn+N-1} \times (L^\infty)^{|\mathcal{I}(S)|}\), one has that
\[
\tilde{\phi}(X_k^0, X_k^1) - \tilde{\phi}(\hat{X}_0, \hat{X}_1) \geq c\gamma(\hat{X}_0^0, Y_k^k, Y_k^T),
\] (71)
for \(k\) large enough, where \((Y^k, \Xi^k)\) are given by Goh transform (62) and \(X^k\) is the solution of the state equation (32) associated to \((\hat{X}_0 + \delta X_0^k, \hat{U} + V^k)\).

Consider the transformed critical cone
\[
\tilde{P}_S^2 := \left\{(Y, \tilde{h}, \Xi) \in (L^2)^{|\mathcal{I}(S)|} \times \mathbb{R} \times (H^1)^{Nn+N-1} : (64)-(65) \text{ hold} \right\}.
\] (72)

The following characterization of \(\gamma\)-growth holds (see Dmitruk 1977 or Dmitruk (1987, Theorem 3.1) for a proof).

Theorem 5 Let \((\hat{U}, \hat{X})\) be such that the qualification condition (38) holds. Then \((\hat{U}, \hat{X})\) is a weak minimum of (TP) that satisfies \(\gamma\)-growth in the weak sense if and only if (69) holds and there exists \(c > 0\) such that
\[
\tilde{\Omega}(Y, \tilde{h}, \Xi) \geq c\gamma(\Xi_0, Y, \tilde{h}) \text{ on } \tilde{P}_S^2.
\] (73)

We are now ready to state the following convergence result for the shooting algorithm.

Theorem 6 If \((\hat{U}, \hat{X})\) is a weak minimum of problem (TP) satisfying the constraint qualification (38) and the uniform positivity condition (73), then the shooting algorithm is locally quadratically convergent.

Proof This is a consequence of the convergence result in Aronna et al. (2013, Theorem 5.4). \(\square\)

Note that in the proof of the above Theorem, it is established that the hypotheses imply that the derivative of the shooting function is injective.

5 Application to a regulator problem

Consider the following regulator problem, where \(T = 5\):
\[
\min \frac{1}{2} \int_0^5 (x_{1,t}^2 + x_{2,t}^2) dt + \frac{1}{2} x_{1,5}^2,
\]
\[
\dot{x}_{1,t} = x_{2,t}, \quad \dot{x}_{2,t} = u_t \in [-1, 1].
\] (74)
subject to the state constraint and initial conditions
\[ x_{2,t} \geq -0.2, \quad x_{1,0} = 0, \quad x_{2,0} = 1. \] (75)

To write the problem in the Mayer form, we introduce an auxiliary state variable given by the dynamics
\[ \dot{x}_3 = \frac{1}{2}(x_1^2 + x_2^2), \quad x_{3,0} = 0. \] (76)

The resulting problem is then
\[
\begin{align*}
\min x_{3,5} &+ \frac{1}{2} x_{1.5}, \\
\dot{x}_1 &= x_2, \quad \dot{x}_2 = u, \quad \dot{x}_3 = \frac{1}{2}(x_1^2 + x_2^2), \\
x_{1,0} &= 0, \quad x_{2,0} = 1, \quad x_{3,0} = 0, \\
-1 &\leq u \leq 1, \quad x_2 \geq -0.2.
\end{align*}
\] (77)

Using the optimal control solver BOCOP Team (2017) we estimated that the optimal control \( \hat{u} \) is a concatenation of a bang arc in the lower bound, followed by a constrained arc and ended with a singular one. Briefly, we can say that the optimal control has a \( B_{-CS} \) structure.

5.1 Checking local optimality

In this subsection we compute analytically the optimal solution of (77) and check that it verifies the second-order sufficient condition for state-constrained control-affine problems proved in Aronna et al. (2016, Theorem 5). While the problem is convex, and hence, satisfying the first-order optimality conditions is enough for proving optimality, the quoted second-order conditions are of interest since they imply the quadratic growth, see Aronna et al. (2016, Definition 3).

To problem (77) we associate the functions
\[ g(x) := -x_2 - 0.2, \quad f_0(x) := \begin{pmatrix} x_2 \\ 0 \\ \frac{1}{2}(x_1^2 + x_2^2) \end{pmatrix}, \quad f_1(x) = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}. \]

So that the optimal control \( \hat{u} \) is equal to -1 on the \( B_- \) arc, and to \( -\frac{g'(\hat{x})f_0(\hat{x})}{g'(\hat{x})f_1(\hat{x})} = 0 \) on \( C \) according to formula (11), where \( \hat{x} \) is the associated optimal state.

The pre-Hamiltonian of (77) reads
\[ H(u, x, p) := p_1 x_2 + p_2 u + \frac{1}{2} p_3 (x_1^2 + x_2^2), \]
where \( p := (p_1, p_2, p_3) \) is the costate.

Over the singular arc \( S \), the inequality \( u_{\min} < \hat{u}_t < u_{\max} \) and the minimum condition of Pontryagin’s Maximum Principle [see e.g. Aronna et al. (2016, equation (2.12))] imply that
\[ H_u = 0. \] (78)

Differentiating in time, (see e.g. Maurer 1976; Aronna et al. 2013), we obtain
\[
H_u = p f_1, \quad \dot{H}_u = p[f_1, f_0], \quad \ddot{H}_u = p[[f_1, f_0], f_0] + \hat{u} p[[f_1, f_0], f_1],
\] (79)
where \([X, Y] := X'Y - Y'X\) denotes the \textit{Lie bracket} associated with a pair of vector fields \(X, Y : \mathbb{R}^n \to \mathbb{R}^n\). In this control-affine case, the control variable does not appear explicitly neither in the expression of \(H_u\) nor in its time derivative \(\dot{H}_u\). So, if \(p[[f_1, f_0], f_1]\) takes only nonzero values along singular arcs, we obtain an expression for the control on singular arcs, namely

\[
\hat{u} = -\frac{p[[f_1, f_0], f_0](\hat{x})}{p[[f_1, f_0], f_1](\hat{x})}. \tag{80}
\]

The involved Lie brackets for this example are

\[
[f_1, f_0] = \begin{pmatrix} -1 \\ 0 \\ -2x_2 \end{pmatrix}, \quad [[f_1, f_0], f_0] = \begin{pmatrix} 0 \\ 0 \\ x_1 \end{pmatrix}, \quad [[f_1, f_0], f_1] = \begin{pmatrix} 0 \\ 0 \\ -1 \end{pmatrix}. \tag{81}
\]

On the other hand, the costate equation on the singular arc \(S\) gives

\[
\dot{p}_1 = -p_3 \hat{x}_1, \quad p_{1.5} = \hat{x}_{1.5}, \\
\frac{dp_2}{dt} = -(p_1 + p_3 \hat{x}_2) + \nu, \quad p_{2.5} = 0, \\
\dot{p}_3 = 0, \quad p_{3.5} = 1, \tag{82}
\]

where \(\mu\) is the multiplier associated with the state constraint, and \(\nu\) is the density of \(\mu\). Thus,

\[
p_3 \equiv 1, \tag{83}
\]

and from (80) and (81) we get

\[
\hat{u} = \hat{x}_1 \text{ on } S. \tag{84}
\]

Moreover, the first-order optimality conditions imply that

\[
0 = H_u = p_2 \text{ on } C \cup S. \tag{85}
\]

Let us write \(\hat{\tau}_1, \hat{\tau}_2\) for the switching times, so that

\[
B_- = [0, \hat{\tau}_1], \quad C = [\hat{\tau}_1, \hat{\tau}_2], \quad S = [\hat{\tau}_2, 5].
\]

Since the control \(\hat{u}\) is constantly equal to \(-1\) on \(B_-\), then

\[
\hat{x}_{2,t} = 1 - t \text{ on } B_-, \tag{86}
\]

until it saturates the state constraint at \(\hat{\tau}_1\). Hence \(1 - \hat{\tau}_1 = -0.2\), so it follows that

\[
\hat{\tau}_1 = 1.2 \tag{87}
\]

and \(B_- = [0, 1.2]\). Consequently,

\[
\hat{x}_{1,t} = t - \frac{t^2}{2} \text{ on } B_. \tag{88}
\]

On \(C = [1.2, \hat{\tau}_2]\), necessarily \(\hat{x}_2 \equiv -0.2\), thus \(u \equiv 0\) and

\[
\hat{x}_{1,t} = 0.48 - 0.2(t - 1.2) = 0.72 - t/5 \text{ on } C. \tag{89}
\]

On the singular arc \(S = [\hat{\tau}_2, 5]\) we get, from the expression of \(\hat{u}\) on \(S\) (84), that \(\hat{x}_1 = \hat{x}_2 = \hat{u} = \hat{x}_1\). Thus

\[
x_{1,t} = c_1e^{5-t} + c_2e^{t-5} \text{ on } S, \tag{90}
\]
for some real constant values $c_1, c_2$. Therefore,
\[\hat{x}_{2,t} = \hat{x}_{1,t} = -c_1 e^{5-t} + c_2 e^{t-5} \quad \text{on} \ S.\] (91)

The stationarity condition $0 = H_u = p_2$ on $S$ yields $0 = \dot{p}_2 = -p_1 - \hat{x}_2$, where the second equality of latter equation follows from (82) and since $v \equiv 0$ on $S$. Thus $p_1 = -\hat{x}_2$ on $S$, so
\[p_{1,t} = c_1 e^{5-t} - c_2 e^{t-5} \quad \text{on} \ S.\] (92)

The transversality condition for $p_1$ (see (82)) implies $c_1 + c_2 = c_1 - c_2$. Thus, $c_2 = 0$ and
\[\dot{x}_1 = -\hat{x}_2 = p_1 = c_1 e^{5-t} \quad \text{on} \ S.\] (93)

Since $-0.2 < x_2, \hat{x}_2$, then $x_1, \hat{x}_2 = 0.2$. Hence, from the expression of $\hat{x}_1$ on $C$ given in (89), we obtain $0.72 - \hat{x}_2/5 = 0.2$ and, consequently
\[\hat{x}_2 = 2.6.\] (94)

Additionally, $-0.2 = x_2, \hat{x}_2 = -c_1 e^{2.4}$ so that $c_1 = 0.2 e^{-2.4}$. At time $\hat{t}_2$ we have that $p_1 = c_1 e^{2.4} = 0.2$ and, from the costate equation (82) and from (89), we have
\[\dot{p}_{1,t} = -\hat{x}_{1,t} = t/5 - 0.72 \leq 2.6/5 - 0.72 < 0 \quad \text{on} \ C = [1.2, 2.6].\] (95)

So $p_1$ is decreasing on $C$ and, recalling (85), this implies that
\[v_t = p_{1,t} + \hat{x}_{2,t} > p_1, \hat{x}_2 - 0.2 = 0 \quad \text{for} \ t \in [\hat{t}_1, \hat{t}_2).\] (96)

Thus the complementarity condition for the state constraint Aronna et al. (2016, equation(3.4)(ii)) holds true.

In order to check that the strict complementarity hypothesis (i) of Aronna et al. (2016, Theorem 5) is satisfied, we will prove that the corresponding strict complementarity condition for the control constraint of Aronna et al. (2016, Definition 4) holds. In view of (95), we get
\[p_{1,t} = 0.2 + (t - \hat{t}_2)^2/10 - 0.72(t - \hat{t}_2).\] (97)

Therefore $p_{1,\hat{t}_1} = 0.2 + (1.4)^2/10 + 0.72 \times 1.4 = 1.404$. On the $B_-$ arc, we have seen that $\hat{x}_1 > 0$ due to (88) and $x_{1,0} = 0$, so that $\dot{p}_1 = -\hat{x}_1 < 0$, and since $p_{1,\hat{t}_1} > 0$, it follows that $p_1$ has values greater than $p_{1,\hat{t}_1} = 1.404$. Therefore, since $\hat{x}_2 > -0.2$ over $B_-$,
\[\dot{p}_2 = -p_1 - \hat{x}_2 < 0 \quad \text{on} \ B_.\] (98)

Since $p_{2,\hat{t}_1} = 0$, we get $p_2 > 0$ on $(0, \hat{t}_1)$ or, equivalently, $H_u > 0$ on $(0, \hat{t}_1)$. We conclude that the strict complementarity condition for the control constraint given in Aronna et al. (2016, Definition 4) holds. This completes the verification of Aronna et al. (2016, Theorem 5 - (i)).

Let us now verify the uniform positivity Aronna et al. (2016, equation (4.6)). The dynamics for the linearized state is
\[\hat{z}_1 = z_2, \quad \hat{z}_2 = v, \quad \hat{z}_3 = \hat{x}_1 z_1 + \hat{x}_2 z_2.\] (99)

Let $C_S$ and $P^2$ denote the strict critical cone and the extended cone [invoking the notation used in Aronna et al. (2016)] at the optimal trajectory $(\hat{u}, \hat{x})$, respectively. Since $\hat{u}$ is $B_\cdot CS$ then, for any $(v, z) \in C_S$, $v = 0$ on the initial interval $B_\cdot$. Consequently,
\[y = 0 \quad \text{on} \ B_\cdot, \quad \text{for all} \ (y, \xi, h) \in P^2.\] (100)
On the other hand, the dynamics for the transformed linearized state is
\[ \dot{\xi}_1 = \xi_2 + y, \quad \dot{\xi}_2 = 0, \quad \dot{\xi}_3 = \hat{x}_1 \xi_1 + \hat{x}_2 \xi_2 + \hat{x}_2 y, \]
(101)
\[ \xi_{1,0} = \xi_{2,0} = \xi_{3,0} = 0. \]
(102)

Take \((y, \xi, h) \in \mathcal{P}_a^2\). Then
\[ \dot{\xi}_2 \equiv 0 \text{ on } [0, 5]. \]
(103)

In view of Aronna et al. (2016, equation (3.15)(i)), we have that \(-\dot{\xi}_2 - y = 0\) on \(C\). Thus, due to (103), we get that
\[ y = 0 \text{ on } B_- \cup C. \]
(104)
Thus, from (101)-(104), we get \(\xi_1 = \xi_3 = 0\) on \(B_- \cup C\). Regarding the last component \(h\) of the considered critical direction \((y, \xi, h) \in \mathcal{P}_a^2\), in view of the linearized cost equation Aronna et al. (2016, equation (3.16)) and due to the fact that there are no final constraints, we get that
\[ \hat{x}_{1,5} \xi_{1,5} + \xi_{3,5} = 0. \]
(105)

Then, we deduce that there is no restriction on \(h\). We obtain
\[ \mathcal{P}_a^2 = \left\{ (y, \xi, h) \in L^2 \times (H^1)^n \times \mathbb{R} : y = \xi_1 = \xi_2 = 0 \text{ on } B_- \cup C, \right. \]
\[ \left. \dot{\xi}_2 = 0 \text{ on } [0, 5], \right. \]
\[ \dot{\xi}_1 = y \text{ and } \dot{\xi}_3 = \hat{x}_1 \xi_1 + \hat{x}_2 y \text{ on } S, \right. \]
\[ \left. (105) \text{ holds} \right\}. \]
(106)

The quadratic forms \(Q\) and \(\Omega\) are given by
\[ Q(v, z) := \int_0^T (z_1^2 + z_2^2)dt + z_1^2; \quad \Omega(y, h, \xi) := \int_0^T (\xi_1^2 + (\xi_2 + y)^2)dt + h^2. \]
(107)
Thus, \(\Omega\) is a Legendre form on \(\{(y, h, \xi) \in L^2 \times \mathbb{R} \times (H^1)^3 : (101)\text{ holds}\}\) and is coercive on \(\mathcal{P}_a^2\). Hence Theorem 5 in Aronna et al. (2016) holds. Consequently, \((\hat{u}, \hat{x})\) is a Pontryagin minimum of problem (77) satisfying the \(\gamma\)-growth condition.

### 5.2 Transformed problem

Here we transform the problem (77) to obtain a problem with neither control nor state constraints, as done in Sect. 3.1.

The optimal control associated with (77) has a \(B_-CS\) structure, as said above. Then we triplicate the number of state variables obtaining the new variables \(X_1, \ldots, X_9\) and we consider two switching times that we write \(X_{10}, X_{11}\). The new problem has only one control variable that corresponds to the singular arc and which we call \(V\). The reformulation of (77) is as follows
\[
\min X_{9,1} + \frac{1}{2} X_{7,1}^2, \\
\dot{X}_1 = X_{10} X_2, \\
\dot{X}_2 = -X_{10}, \\
\dot{X}_3 = \frac{1}{2} X_{10} (X_1^2 + X_2^2), \\
\dot{X}_4 = (X_{11} - X_{10}) X_5.
\]
\[
\begin{align*}
\dot{X}_5 &= 0, \\
\dot{X}_6 &= \frac{1}{2} (X_{11} - X_{10})(X_4^2 + X_5^2), \\
\dot{X}_7 &= (5 - X_{11})X_8, \\
\dot{X}_8 &= (5 - X_{11})V, \\
\dot{X}_9 &= \frac{1}{2} (5 - X_{11})(X_7^2 + X_8^2), \\
\dot{X}_{10} &= 0, \\
\dot{X}_{11} &= 0, \\
X_{1,0} &= 0, \quad X_{2,0} = 1, \quad X_{3,0} = 0, \\
X_{1,1} &= X_{4,0}, \quad X_{2,1} = X_{5,0}, \quad X_{3,1} = X_{6,0}, \\
X_{4,1} &= X_{7,0}, \quad X_{5,1} = X_{8,0}, \quad X_{6,1} = X_{9,0}, \\
X_{2,1} &= 0.2, \quad \text{(or } g(x_2(\tau_2)) = 0). 
\end{align*}
\]

From (84) we deduce that \( V = X_7 \).

We solved problem (108) by the shooting algorithm proposed in Sect. 3. The graphics of the optimal control and states are shown in Fig. 1 in the original variables \( u \) and \( x \), and the corresponding costate variables \( p_1, p_2, p_3 \) are displayed in Fig. 2.

In our numerical tests we take 1000 time steps. The optimal switching times obtained numerically are \( \hat{\tau}_1 = 1.2 \) and \( \hat{\tau}_2 = 2.6036023 \), so these values agree with the ones founded analytically in (87) and (94), while the optimal cost is 0.3934884 and the shooting function evaluated at the optimal trajectory is \( 5 \times 10^{-6} \).
Remark 4 In order to compare with existing methods, we have solved the same problem using GEKKO Python (Beal et al. 2018). We have tested different variable definitions for the control input and we found the best result by setting the control as a manipulated variables (Beal et al. 2018). The results are shown in Fig. 3. On the right of this figure, we exhibit a zoom around the second switching point $\hat{\tau}_2$ of the optimal control. We can see that the method shows a discontinuity of the control at $\hat{\tau}_2$, but that the approximation of $\hat{\tau}_2$ is between 2.57 and 2.58, while we have calculated analytically that $\hat{\tau}_2 = 2.6$ and our shooting algorithm finds the approximate value 2.6036023. GEKKO was tested with up to 1000 time steps, while our shooting algorithm was run with 150 time steps. This indicates that our method is more accurate when it comes to finding switching times and approximating bang-singular solutions. This feature of shooting methods has been already observed in the literature (see e.g. Trélat 2012).

6 Conclusion

We have shown that, for problems that are affine w.r.t. the control, and for which the time interval can be partitioned in a finite set of arcs, the shooting algorithm converges locally quadratically if a second-order sufficient condition holds, and thus the method may be an efficient way to get a highly accurate solution.

The essential tool was to formulate a transformed problem. We think that this approach could be extended to more general problems with several state constraints and control variables, the latter possibly entering nonlinearly in the problem. Problems with vector control are important in complex models, see e.g. Leparoux et al. (2022a, b) where they studied a control-affine problem with vector control, state constraints, but no singular arcs, generically, in the state-constrained solution. When considering several controls and state constraints, it becomes important to take into account the possibility of having high-order state constraints.
