Thiolated DAB Dendrimer-Gold Nanoparticles
Self-Assembled Monolayer as Covalent Support for Direct Electrochemistry of HRP and Sensing Applications

Abstract
A thiolated DAB dendrimer has been employed to bond gold nanoparticles of several sizes in order to obtain an electrocatalytic framework for the covalent immobilization and direct electrochemistry of horseradish peroxidase (HRP). This biosensor must represent the basis for developing a lot of oxidase-peroxidase biensymatic biosensors and heavy metals biosensors based on the HRP inhibition. The kinetic study of the modified electrodes showed that the 5 nm and 16 nm gold nanoparticles are the most efficient to contact with the HRP active centre and the optimized biosensor allow to measure hydrogen peroxide at -0.3 V applied potential in linear ranges of 1-5000 and 1-140 or 140-5000 respectively with high sensitivities of 418.6 and 266.3 μA mM⁻¹ cm⁻² respectively too with low detection limits of 5 and 9 nM and fast response. The obtained apparent Michaelis-Menten constants, were 0.16 and 0.84 mM respectively. Both are significantly lower than the intrinsic K’ₘ, revealing the very high enzymatic efficiency of the developed devices.

Keywords: Biosensor; Self-Assembled Multilayer Structure; Thiolated DAB Dendrimer; Horseradish Peroxidase.

Introduction
HRP is widely used in hydrogen peroxide amperometric biosensors of 2nd and 3rd [1-5] generations because the possibility of stabilish direct electrochemistry with the electrode material. The H₂O₂ is a by-product of a lot of oxidase enzymatic reactions, consequently has great interest for sensing in pharmaceutical or industrial processes as well as in clinical, food or environmental analysis. Also, heavy metal ions inhibit the activity of HRP and therefore the HRP biosensors can act as inhibition-based biosensor for the determination of heavy metals [6,7]. In order to develop 3rd generation’s biosensors, three-dimensional nanoparticle materials as gold nanoparticles (AuNPs), constitutes a favourable surface for the immobilization of biomolecules because maintain their biological activity and favouring longer stability and higher reproducibility [8] by their ability to form S-Au bonds with the thiol and amine groups. Moreover, due to their nanometric size, AuNPs refine the enzymes in the proper orientation onto the electrode surface, acting as nanoelectrodes. On the other hand, The dendrimers combine the physical and chemical desired properties with tuneable solubility and surface reactivity. In order to conform the assembled layers, a thiol-functionalized dendrimer has been used to form S-bonds with the AuNPs. In this work, we present the kinetic and analytical characterization of a new sensitive DAB-S-AuNPs-HRP peroxide biosensor with the intention of develop the basis of different biensymatic oxidase-peroxidase or inhibition biosensors.

Materials and Methods
The DAB-SH dendrimer (Figure 1) has sixty-four thiol terminal units and was synthesized as previously described [9]. Horseradish peroxidase (HRP, 222 units mg⁻¹), colloidal gold nanoparticles (Au) (5 nm diameter) and HAuCl₄·3H₂O were purchased from Sigma-Aldrich. K₃Fe(CN)₆, K₄Fe(CN)₆, Na₂citrate and other chemicals were analytical grade and were used without further purification. The hydrogen peroxide solutions were previously normalized by the permanganate titration method. Ultrapure water was used for all the purposes. AuC with diameters of 16 nm and 41 nm were synthesized according to the Turkelvich method [10], based in citrate as reductor, (0.5 or 0.25 ml of 1% sodium citrate solution were added to 50 ml of a stirred boiling aqueous solution containing 0.5 ml of 1% HAuCl₄ to obtain 16 nm and 41 nm sizes, respectively).
The GC disk electrodes were polished using 0.1 μm of alumina powder and rinsed in ultrapure water in an ultrasonic bath. In order to achieve the anchorage of SH groups to the electrode surface, a first layer of AuNPs were electrodeposited on the GC bare electrode by nine potential cycles between 0.2 and −0.4 V vs SCE in a 10 mM H\textsubscript{2}AuCl\textsubscript{4} deaerated solution at scan rate of 0.02 V s\textsuperscript{−1}. Next 0.8 μl of a solution of the dendrimer (approximately 10\textsuperscript{−4} mM) in 60% sodium hydroxide was dropped onto the AuNPs-electrode surface and maintained for 3 hours at room temperature. Next, the S-DAB/AuNPs/GC electrode was dipped in the corresponding Au\textsubscript{c} suspension for 15 hours and washed with phosphate buffer pH 7 and ultrapure water.

The enzyme immobilization was carried out by dipping the modified electrodes in a 1.0 mg mL\textsuperscript{−1} of HRP solution in the phosphate buffer pH 7.0 at room temperature for 4 hours. The biosensors were rinsed with the phosphate buffer and preserved in the buffer solution at 4 °C when not in use. All electrochemical measurements were carried out using an Ecochemie BV Autolab PGSTAT 12. The experiments were performed in a conventional three-electrode cell at 20–21 °C with a GC disk of 3 mm diameter as working electrode, a Pt wire as auxiliary electrode and a saturated Calomel (SCE) as reference electrode. In the steady-state measurements, an Autolab rotating-disc electrode was used. 0.01 M phosphate buffer pH 7.0 was used as supporting electrolyte.

**Results**

Figure 2 shows the voltammetric profile of the modified electrode before and after the enzyme immobilization. As can be see, a quasi-reversible redox system with \( E_\text{a} = 0.225 \) V and \( E_\text{c} = 0.185 \) V related to the oxide formation and reduction on the Au\textsubscript{c} surface appears after the assembly of the Au\textsubscript{c} to dendrimer’s thiol groups [11]. This quasi-reversible system allow us to study the kinetics of electrodes modified with the three Au\textsubscript{c} sizes applying the Laviron model [12], based in the variation of the anodic and cathodic peak potentials with the scan rate. Cyclic voltammograms of modified electrodes show an increase of the peak potential difference, \( \Delta E_\text{p} \), as the sweep rate increases, indicating certain charge transfer kinetics limitation. The homogeneous rate constants \( k_s \) were calculated in agreement with the Laviron’s model from the supplied data for \( \Delta E_\text{p} < 200/n \text{ mV} \) with polynomial fit:

\[
Fvn/RT_{\text{k}} = 0.0003 \Delta E_p^2 + 0.491 \left( R^2 = 0.9992 \right)
\]

Where \( F \) is the Faraday constant, \( n \) is the stoichiometric number of electrons involved, \( R \) is the gas constant and \( T \) is the absolute temperature. The average \( k_s \) obtained by this way for Au\textsubscript{c5}/S-DAB/AuNPs/GC, Au\textsubscript{c16}/S-DAB/AuNPs/GC and Au\textsubscript{c41}/S-DAB/AuNPs/GC electrodes were respectively 228, 322 and 308 s\textsuperscript{−1}. These values constants are indicative of little kinetic limitations and let us consider the Au\textsubscript{c} with diameter of 16 nm as the most adequate size to the electron transfer with the electrode. Next, we must study if the best electron transfer in the electrode conformation is also the more effective HRP-Au mediation. The kinetic and analytical
characterization of the HRP/Au/S-DAB/AuNPs/GCE electrodes were studied for the amperometric hydrogen peroxide reduction at working potential -0.3 V, selected as optimum. Figure 3 shows the calibration plots and the amperometric response inset in Figure 3.

Conclusion

This work presents the kinetic and analytical study of electrodes modified with a thiolated DAB dendrimer with different sized gold nanoparticles, forming a self-assembled monolayer. The modified electrodes constitute a bioelectrochemical system for applications in the development of more sensitive and stable oxidase bienzymatic biosensors or in inhibition-based sensors. All the surfaces showed a fast electron transfer and good analytical response, principally HRP/Auc5/S-DAB/AuNPs/GC and HRP/Auc16/S-DAB/AuNPs/GC electrodes in concentration ranges of 0-120 and 0-5000, with sensitivities of 418.6 and 266.3 µA mM⁻¹ cm⁻² respectively, and very low detection limits. In addition, the self-assembled monolayer framework allowed the efficient immobilization of HRP with apparent Michaelis-Menten constants lower than the intrinsic one. Consequently, the biosensor achieves our objective and we hope that be the start of several and different derived biosensors.
