Rational extension of Newton diagram for the positivity of $1F_2$ hypergeometric functions and Askey-Szegö problem

Yong-Kum Cho, Seok-Young Chung and Hera Yun

March 15, 2022

Abstract. We present a rational extension of Newton diagram for the positivity of $1F_2$ generalized hypergeometric functions. As an application, we give upper and lower bounds for the transcendental roots $\beta(\alpha)$ of

$$\int_{0}^{j_{\alpha,2}} t^{-\beta} J_{\alpha}(t) dt = 0 \quad (-1 < \alpha \leq 1/2),$$

where $j_{\alpha,2}$ denotes the second positive zero of Bessel function $J_{\alpha}$.

Keywords. Bessel function, generalized hypergeometric function, Newton diagram, positivity, Saalschützian.

2010 Mathematics Subject Classification: 26D15, 33C10, 33C20.

1 Introduction

We consider the problem of determining $(\alpha, \beta)$ for

$$\int_{0}^{x} t^{-\beta} J_{\alpha}(t) dt \geq 0 \quad (x > 0), \quad (1.1)$$

where $J_{\alpha}$ stands for the first-kind Bessel function of order $\alpha$. For the sake of convergence and application, it will be assumed $\alpha > -1, \beta < \alpha + 1$.

Owing to various applications, the problem has been studied by many authors over a long period of time. In connection with the monotonicity
of Bessel functions, for instance, the problem dates back to Bailey [5] and Cooke [9]. We refer to Askey [1], [2] for further historical backgrounds.

By interpolating known results for some special cases in certain way, Askey [2] described an explicit range of parameters as follows.

**Theorem A.** Let $\mathcal{P}$ be the set of $(\alpha, \beta) \in \mathbb{R}^2$ defined by

$$\mathcal{P} = \{\alpha > -1, \ 0 \leq \beta < \alpha + 1\} \cup \{\alpha \geq 0, \ \max \left( -\alpha, -\frac{1}{2} \right) \leq \beta \leq 0 \}. $$

(i) For each $(\alpha, \beta) \in \mathcal{P}$, the inequality of (1.1) holds with strict positivity unless it coincides with $(1/2, -1/2)$.

(ii) If $\alpha > -1$, $\beta < -1/2$, then (1.1) does not hold.

As it is shown in Figure 1, the positivity region $\mathcal{P}$ represents an infinite polygon enclosed by four boundary lines $\beta = \alpha + 1$, $\beta = 0$, $\beta = -\alpha$, $\beta = -1/2$.

By part (ii), observed by Steinig [20], Theorem A leaves only the trapezoid

$$\mathcal{T} = \left\{-1 < \alpha < \frac{1}{2}, \ -\frac{1}{2} \leq \beta < \min (0, -\alpha)\right\}$$

(1.2)
undetermined in regards to problem (1.1).

As for this missing region, the best possible range of parameters is known in an implicit formulation which involves roots of certain transcendental equations. To be precise, we follow Askey’s summary [2] to state

**Theorem B.** Let $j_{\alpha,2}$ be the second positive zero of $J_{\alpha}(t)$, $\alpha > -1$.

(i) For $-1 < \alpha \leq 1/2$, (1.1) holds if and only if $\beta \geq \beta(\alpha)$, where $\beta(\alpha)$ denotes the unique zero of

$$A(\beta) = \int_0^{j_{\alpha,2}} t^{-\beta} J_{\alpha}(t) dt, \quad -1/2 < \beta < \alpha + 1. \quad (1.3)$$

(ii) As a special case of (1.1), the inequality

$$\int_0^x t^{-\alpha} J_{\alpha}(t) dt \geq 0 \quad (x > 0) \quad (1.4)$$

holds for $\alpha \geq \bar{\alpha}$, where $\bar{\alpha}$ denotes the unique zero of

$$G(\alpha) = \int_0^{j_{\alpha,2}} t^{-\alpha} J_{\alpha}(t) dt, \quad \alpha > -1/2. \quad (1.5)$$

Regarding part (i), the existence and uniqueness of such a zero as well as the positivity of (1.1) is due to Makai [17], [18] when $-1/2 < \alpha < 1/2$, Askey and Steinig [3] when $-1 < \alpha < -1/2$, respectively. The remaining case $\alpha = \pm 1/2$ follows by an integration by parts.

Part (ii) is obtained by G. Szegö [10] much earlier and reproved by Koumandos [14], Lorch, Muldoon and P. Szegö [15]. Since (1.4) is a special case of (1.1) and part (i) gives a necessary and sufficient condition for (1.1), it is equivalent to define $\bar{\alpha}$ as the unique solution of $\beta(\alpha) = \alpha$.

A major drawback of Theorem B lies in the intricate nature of the zeros $\beta(\alpha)$ and $\bar{\alpha}$. As it is pointed out by Askey [2], in fact, essentially nothing has been known yet on the nature of $\beta(\alpha)$ and $\bar{\alpha}$ except a few numerical simulations and trivial limiting behavior $\lim_{\alpha \to -1+} \beta(\alpha) = 0$.

In this paper we aim at extending the positivity region $P$ of Theorem A and thereby obtaining informative bounds of $\beta(\alpha)$ and $\bar{\alpha}$ which provide an insight into their nature and an approximating means in practical use.

By making use of the identity (Luke [16], Watson [21])

$$J_{\alpha}(t) = \frac{1}{\Gamma(\alpha + 1)} \left( \frac{t}{2} \right)^{\alpha} _0F_1 \left( \alpha + 1; -\frac{t^2}{4} \right) \quad (\alpha > -1) \quad (1.6)$$
and integrating termwise, it is easy to see

\[
\int_0^x t^{-\beta} J_\alpha(t)\,dt = \frac{x^{\alpha-\beta+1}}{2^\alpha(\alpha - \beta + 1)\Gamma(\alpha + 1)} \times \begin{bmatrix}
\frac{\alpha-\beta+1}{2} & \frac{\alpha-\beta+3}{2} \\
\alpha + 1 & \frac{\alpha-\beta+3}{2}
\end{bmatrix} \left[ -\frac{x^2}{4} \right]
\]

(1.7)

and hence problem (1.1) is equivalent to the problem of positivity for the functions defined on the right side of (1.7).

More generally, we shall be concerned with the positivity of generalized hypergeometric functions of type

\[
_{1}F_{2} \left[ \begin{array}{c}
a \\
\frac{a}{b}, c
\end{array} \bigg| -\frac{x^2}{4} \right] (x > 0)
\]

(1.8)

with parameters \(a > 0\), \(b > 0\), \(c > 0\). In the recent work [8], to be explained in detail, a positivity criterion for the functions of type (1.8) is established in terms of the Newton diagram associated to \{\((a + 1/2, 2a), (2a, a + 1/2)\}\}. Due to certain region of parameters left undetermined, however, it turns out that an application of the criterion to (1.7) yields Theorem A immediately but does not cover the missing region \(T\) either.

The main purpose of this paper is to give an extension of the Newton diagram which leads to an improvement of Theorem A in an explicit way and provides information on the nature of \(\beta(\alpha)\) and \(\bar{\alpha}\).

As it is more or less standard in the theory of special functions, we shall carry out Gasper’s sums of squares method [12] for investigating positivity, which essentially reduces the matter to how to determine the signs of \(_4F_3\) terminating series given in the form

\[
_{4}F_{3} \left[ \begin{array}{c}
-n, n + \alpha_1, \alpha_2, \alpha_3 \\
\beta_1, \beta_2, \beta_3
\end{array} \right], \quad n = 1, 2, \ldots
\]

(1.9)

for appropriate values of \(\alpha_j, \beta_j\) expressible in terms of \(a, b, c\).

From a technical point of view, if we express (1.9) as a finite sum with index \(k\), it is the alternating factor \((-n)_k\) that causes main difficulties in analyzing its sign. To circumvent, we shall apply Whipple’s transformation formula to convert it into a \(_7F_6\) terminating series which does not involve such an alternating factor. By estimating a lower bound for the transformed series, we shall deduce positivity in an inductive way.
While Askey and Szegö studied problem (1.1) primarily as a limiting case for the positivity of certain sums of Jacobi polynomials, there are many other applications and generalizations (see e.g. [10, 12, 13, 19]). As an exemplary generalization, we shall consider the integrals of type

$$\int_0^x \frac{(x^2 - t^2)\gamma}{t^\beta} J_\alpha(t) dt \quad (x > 0),$$

and obtain the range of parameters for its positivity by applying our new criterion, which improves the work of Gasper [12] considerably.

2 Preliminaries

As it is standard, given nonnegative integers $p, q$, we shall define and write $p \, F \, q$ generalized hypergeometric functions in the form

$$p \, F \, q \left[ \begin{array}{c} \alpha_1, \cdots, \alpha_p \\ \beta_1, \cdots, \beta_q \end{array} \right] \left| z \right] = \sum_{k=0}^{\infty} \frac{(\alpha_1)_k \cdots (\alpha_p)_k}{(\beta_1)_k \cdots (\beta_q)_k} z^k \quad (z \in \mathbb{C}), \tag{2.1}$$

where the coefficients are written in Pochhammer’s notation, that is, for any $\alpha \in \mathbb{R}$, $(\alpha)_k = \alpha(\alpha+1) \cdots (\alpha+k-1)$ when $k \geq 1$ and $(\alpha)_0 = 1$. In the case when $z = 1$, we shall delete the argument $z$ in what follows.

A function of type (2.1) is said to be Saalschützian when the parameters satisfy the condition $1 + \alpha_1 + \cdots + \alpha_p = \beta_1 + \cdots + \beta_q$. If one of the numerator-parameters $\alpha_j$ is a negative integer, e.g., $\alpha_1 = -n$ with $n$ a positive integer, then it becomes a terminating series given by

$$p \, F \, q \left[ \begin{array}{c} -n, \alpha_2, \cdots, \alpha_p \\ \beta_1, \cdots, \beta_q \end{array} \right] \left| z \right] = \sum_{k=0}^{n} (-1)^k \frac{(n)_k}{(\beta_1)_k \cdots (\beta_q)_k} z^k. \tag{2.2}$$

For the generalized hypergeometric functions of type (2.1) which are both terminating and Saalschützian, there are a number of formulas available for summing or transforming into other terminating series. Of particular importance will be the following extracted from Bailey [4].

(i) (Saalschütz’s formula, [4] 2.2(1))

If $1 + \alpha_1 + \alpha_2 = \beta_1 + \beta_2$, then

$$3 \, F \, 2 \left[ \begin{array}{c} -n, n + \alpha_1, \alpha_2 \\ \beta_1, \beta_2 \end{array} \right] = \frac{(\beta_1 - \alpha_2)_n (\beta_2 - \alpha_2)_n}{(\beta_1)_n (\beta_2)_n}. \tag{2.3}$$
(ii) (Whipple’s transformation formula, [4 4.3(4)])

If \(1 + \alpha_1 + \alpha_2 + \alpha_3 = \beta_1 + \beta_2 + \beta_3\), then

\[
\begin{align*}
4F_3 \left[ -n, n + \alpha_1, \alpha_2, \alpha_3 \bigg| \beta_1, \beta_2, \beta_3 \right] &= \frac{(1 + \alpha_1 - \beta_3)_n (\beta_3 - \alpha_2)_n}{(1 + \sigma)_n (\beta_3)_n} \times \\
7F_6 \left[ \sigma, 1 + \sigma/2, -n, n + \alpha_1, \frac{n + 1 + \alpha_2 - \beta_3}{\beta_1 - \alpha_3}, \frac{\beta_2 - \alpha_3}{\beta_1} \bigg| \sigma/2, n + 1 + \sigma, -n + 1 + \alpha_2 - \beta_3, 1 + \alpha_1 - \beta_3, \frac{\beta_1 - \alpha_3}{\beta_2}, \frac{\beta_2}{\beta_1} \right],
\end{align*}
\]

where we put \(\sigma = \alpha_1 + \alpha_2 - \beta_3\). It is a modification of the original form suitable to the present application and arranged in such a way that the sums of columns of the \(6F_6\) terminating series, obtained from deleting \(\sigma\), are all equal to \(1 + \sigma\).

3 Positivity of \(4F_3\) terminating series

The purpose of this section is to prove the following positivity result for a special class of terminating \(4F_3\) generalized hypergeometric series, which will be crucial in our subsequent developments.

**Lemma 3.1.** For each positive integer \(n\), put

\[\Theta_n = 4F_3 \left[ -n, n + \alpha_1, \alpha_2, \alpha_3 \bigg| \beta_1, \beta_2, \beta_3 \right].\]

Suppose that \(\alpha_j, \beta_j\) satisfy the following assumptions simultaneously:

\[
\begin{align*}
\text{(A1)} & \quad 1 + \alpha_1 + \alpha_2 + \alpha_3 = \beta_1 + \beta_2 + \beta_3, \\
\text{(A2)} & \quad 0 < \alpha_2 < \beta_3 \leq 2 + \alpha_1, \\
\text{(A3)} & \quad 0 < \alpha_3 < \min(\beta_1, \beta_2), \\
\text{(A4)} & \quad (1 + \alpha_1)\alpha_2\alpha_3 \leq \beta_1 \beta_2 \beta_3.
\end{align*}
\]

Then \(\Theta_1 \geq 0\) and \(\Theta_n > 0\) for all \(n \geq 2\).

**Proof.** We apply Whipple’s transformation formula to transform \(\Theta_n\) into a product of \(3F_2\) and \(7F_6\) terminating series as stated in (2.4). By using

\[
(\alpha)_n = (\alpha)_k (k + \alpha)_{n-k}, \quad (\alpha)_n = (\alpha)_{n-k} (n - k + \alpha)_k,
\]
valid for any real number $\alpha$ and $k = 0, \ldots, n$, it is equivalent to

$$
\Theta_n = \frac{1}{(1 + \sigma)n(\beta_3)_n} \cdot \Omega_n ,
$$

$$
\Omega_n = \sum_{k=0}^{n} \binom{n}{k} (k + 1 + \alpha_1 - \beta_3)n_{n-k}(\beta_3 - \alpha_2)n_{n-k} \frac{(n + \alpha_1)_k}{(n + 1 + \sigma)_k} \times \frac{(\alpha_2)_k(\beta_1 - \alpha_3)_k(\beta_2 - \alpha_3)_k(\sigma)_k(1 + \sigma/2)_k}{(\beta_1)_k(\beta_2)_k(\sigma/2)_k},
$$

where $\sigma = \alpha_1 + \alpha_2 - \beta_3$ and the last factor must be understood as

$$
\frac{(\sigma)_k(1 + \sigma/2)_k}{(\sigma/2)_k} = \left\{ \begin{array}{ll}
1 & \text{for } k = 0, \\
(1 + \sigma)_{k-1}(2k + \sigma) & \text{for } k \geq 1.
\end{array} \right.
$$

By the Saalschützian condition of (A1) and (A3), we observe that

$$1 + \sigma = \beta_1 + \beta_2 - \alpha_3 > 0$$

and hence the positivity or nonnegativity of $\Theta_n$ reduces to that of $\Omega_n$. We also note that the assumptions of (A1), (A2), (A3) imply

$$1 + \alpha_1 = \beta_1 + (\beta_2 - \alpha_3) + (\beta_3 - \alpha_2) > 0.$$

As a consequence, if $\beta_3 \leq 1 + \alpha_1$, then the first term is nonnegative and all of other terms are positive so that $\Omega_n > 0$ for each $n \geq 1$. Therefore it suffices to deal with the case $\beta_3 > 1 + \alpha_1$, which will be assumed hereafter.

In the special case $n = 1$, it is a matter of algebra to factor out

$$
\Omega_1 = (1 + \alpha_1 - \beta_3)(\beta_3 - \alpha_2) + \frac{(1 + \alpha_1)\alpha_2(\beta_1 - \alpha_3)(\beta_2 - \alpha_3)}{\beta_1\beta_2}
$$

$$
= \frac{(\beta_1 + \beta_2 - \alpha_3)[\beta_1\beta_2\beta_3 - (1 + \alpha_1)\alpha_2\alpha_3]}{\beta_1\beta_2},
$$

which clearly shows $\Omega_1 \geq 0$ under the stated assumptions.

For $n \geq 2$, we shall deduce the strict positivity of $\Omega_n$ by considering each case $\beta_3 \geq 1 + \alpha_2, \beta_3 < 1 + \alpha_2$ separately in the following manner.

**I. The case $\beta_3 \geq 1 + \alpha_2$.** We claim that

$$
\Omega_n > (2 + \alpha_1 - \beta_3)n_{n-1}(1 + \beta_3 - \alpha_2)n_{n-1}\Omega_1.
$$

7
To verify, we observe that each term of $\Omega_n$ except the first one is positive so that $\Omega_n$ exceeds the sum of the first two terms, which implies

$$\Omega_n > (2 + \alpha_1 - \beta_3)_{n-1}(\beta_3 - \alpha_2)_n \times \left[ 1 + \alpha_1 - \beta_3 + \frac{n(n + \alpha_1)(\alpha_2(\beta_1 - \alpha_3)(\beta_2 - \alpha_3)(2 + \sigma))}{(n + 1 + \sigma)(n - 1 + \beta_3 - \alpha_2)\beta_1\beta_2} \right]. \quad (3.6)$$

If we set

$$f(n) = \frac{n(n + \alpha_1)}{(n + 1 + \sigma)(n - 1 + \beta_3 - \alpha_2)} = \frac{n^2 + \alpha_1 n}{n^2 + \alpha_1 n + (1 + \sigma)(\beta_3 - 1 - \alpha_2)}$$

and regard $n$ as a continuous variable, then the derivative of $f$ is given by

$$f'(n) = \frac{(2n + \alpha_1)(1 + \sigma)(\beta_3 - 1 - \alpha_2)}{[n^2 + \alpha_1 n + (1 + \sigma)(\beta_3 - 1 - \alpha_2)]^2}.$$

Due to the case assumption, it shows $f'(n) \geq 0$ on the interval $[1, \infty)$ and hence we may conclude $f(n) \geq f(1)$, that is,

$$\frac{n(n + \alpha_1)}{(n + 1 + \sigma)(n - 1 + \beta_3 - \alpha_2)} \geq \frac{1 + \alpha_1}{(2 + \sigma)(\beta_3 - \alpha_2)}.$$

Reflecting this estimate in (3.6) and simplifying, we obtain

$$\Omega_n > (2 + \alpha_1 - \beta_3)_{n-1} \frac{(\beta_3 - \alpha_2)_n}{(\beta_3 - \alpha_2)} \times \left[ (1 + \alpha_1 - \beta_3)(\beta_3 - \alpha_2) + \frac{(1 + \alpha_1)(\alpha_2(\beta_1 - \alpha_3)(\beta_2 - \alpha_3))}{\beta_1\beta_2} \right]$$

$$= (2 + \alpha_1 - \beta_3)_{n-1}(1 + \beta_3 - \alpha_2)_{n-1}\Omega_1,$$

which proves (3.5). The strict positivity of $\Omega_n$ is an immediate consequence of this inequality and the nonnegativity of $\Omega_1$.

II. The case $\beta_3 < 1 + \alpha_2$. In this case, we shall deduce the strict positivity of $\Omega_n$ by induction on $n$. To simplify notation, we put

$$A_{n,k} = \binom{n}{k}(k + 1 + \alpha_1 - \beta_3)_{n-k}(\beta_3 - \alpha_2)_{n-k} \frac{(n + \alpha_1)_k}{(n + 1 + \sigma)_k},$$

$$B_k = \frac{(\alpha_2)_k(\beta_1 - \alpha_3)_k(\beta_2 - \alpha_3)_k(\sigma)_k(1 + \sigma/2)_k}{(\beta_1)_k(\beta_2)_k(\sigma/2)_k}.$$
so that \( \Omega_n = \sum_{k=0}^{n} A_{n,k} B_k \). By the stated assumptions and (3.3), we note that \( A_{n,0} < 0 \) but \( A_{n,1} \geq 0 \), \( A_{n,k} > 0 \) for \( 2 \leq k \leq n \) and \( B_k > 0 \) for each \( 0 \leq k \leq n \). In this notation we claim that

\[
\Omega_{n+1} > A_{n+1,n+1} B_{n+1} + \left[ \frac{(n+1)(n+1 + \alpha_1 - \beta_3)(n+1 + \sigma)}{n + \alpha_1} \right] \Omega_n. \tag{3.7}
\]

As it is already shown that \( \Omega_1 \geq 0 \), once (3.7) were true, it follows by an obvious induction argument that we may conclude \( \Omega_n > 0 \) for all \( n \geq 2 \).

To verify, we make use of the identities

\[
\binom{n+1}{k} = \binom{n}{k} \frac{n+1}{n+1-k},
\]

\[
(k+1 + \alpha_1 - \beta_3)_{n+1-k} = (k+1 + \alpha_1 - \beta_3)_{n-k} (n+1 + \alpha_1 - \beta_3),
\]

\[
(\beta_3 - \alpha_2)_{n+1-k} = (\beta_3 - \alpha_2)_{n-k} (n-k + \beta_3 - \alpha_2),
\]

\[
(n+1 + \alpha_1)_k = (n+\alpha_1)_k \frac{n+k+\alpha_1}{n+\alpha_1},
\]

\[
(n+2 + \sigma)_k = (n+1 + \sigma)_k \frac{n+1+k+\sigma}{n+1+\sigma},
\]

to write \( A_{n+1,k} \) in the form

\[
A_{n+1,k} = A_{n,k} \left[ \frac{(n+1)(n+1 + \alpha_1 - \beta_3)(n+1 + \sigma)}{n + \alpha_1} \right] g_n(k),
\]

\[
g_n(k) = \frac{(k+n+\alpha_1)(k-n+\alpha_2 - \beta_3)}{(k-n-1)(k+n+1+\sigma)}
\]

\[
= \frac{k^2 + \sigma k - (n+1)(n+\beta_3 - \alpha_2)}{k^2 + \sigma k - (n+1)(n+1+\sigma)}.
\]

Regarding \( k \) as a continuous variable as before, we differentiate

\[
g'_n(k) = \frac{(2k+\sigma)(\beta_3 - \alpha_2 - 1)(2n+1 + \alpha_1)}{[k^2 + \sigma k - (n+1)(n+1+\sigma)]^2}.
\]

By the case assumption, it shows \( g'_n(k) < 0 \) on the interval \([1, \infty)\). In view of the limiting behavior \( g_n(k) \rightarrow 1 \) as \( k \rightarrow \infty \), hence, we may conclude \( g_n(k) > 1 \) for \( k = 1, \cdots, n \), which leads to the estimate

\[
A_{n+1,k} \geq A_{n,k} \left[ \frac{(n+1)(n+1 + \alpha_1 - \beta_3)(n+1 + \sigma)}{n + \alpha_1} \right] \tag{3.8}
\]

for each \( k = 1, \cdots, n \) with strict inequalities when \( k \geq 2 \).
As for the initial term $A_{n+1,0}$, we may write

$$A_{n+1,0} = A_{n,0} \left[ (n + 1 + \alpha_1 - \beta_3)(n + \beta_3 - \alpha_2) \right].$$

We observe that an upper bound for the last factor is given by

$$n + \beta_3 - \alpha_2 < \frac{(n + 1)(n + 1 + \sigma)}{n + \alpha_1},$$

which follows easily from the sign of cross difference

$$(n + 1)(n + 1 + \sigma) - (n + \beta_3 - \alpha_2)(n + \alpha_1)$$

$$= 2(1 + \alpha_2 - \beta_3)n + (1 + \alpha_1)(1 + \alpha_2 - \beta_3)$$

$$= (1 + \alpha_2 - \beta_3)(2n + 1 + \alpha_1) > 0$$

due to the case assumption. Since $A_{n,0} < 0$, this upper bound gives

$$A_{n+1,0} > A_{n,0} \left[ \frac{(n + 1)(n + 1 + \alpha_1 - \beta_3)(n + 1 + \sigma)}{n + \alpha_1} \right]. \quad (3.9)$$

Multiplying each term of (3.8), (3.9) by $B_k$ and adding up, we obtain

$$\Omega_{n+1} = A_{n+1,n+1}B_{n+1} + \sum_{k=0}^{n} A_{n+1,k}B_k$$

$$> A_{n+1,n+1}B_{n+1} + \left[ \frac{(n + 1)(n + 1 + \alpha_1 - \beta_3)(n + 1 + \sigma)}{n + \alpha_1} \right] \sum_{k=0}^{n} A_{n,k}B_k$$

$$= A_{n+1,n+1}B_{n+1} + \left[ \frac{(n + 1)(n + 1 + \alpha_1 - \beta_3)(n + 1 + \sigma)}{n + \alpha_1} \right] \Omega_n,$$

which proves (3.7) and our proof is now complete. \qed

### 4 Rational extension of Newton diagram

In this section we aim to extend the aforementioned positivity criterion of [8] for the generalized hypergeometric functions of type (1.8).

To state the criterion precisely, we recall that the Newton diagram associated to a finite set of planar points $\{(\alpha_i, \beta_i) : i = 1, \cdots, m\}$ refers to the closed convex hull containing

$$\bigcup_{i=1}^{m} \left\{ (x, y) \in \mathbb{R}^2 : x \geq \alpha_i, \ y \geq \beta_i \right\}.$$
For each \( a > 0 \), we denote by \( O_a \) the set of \((b, c) \in \mathbb{R}^2_+\) defined by

\[
O_a = \begin{cases} 
  \left\{ a < b < a + \frac{1}{2}, \ c \geq 3a + \frac{1}{2} - b \right\} \\
  \cup \left\{ a < c < a + \frac{1}{2}, \ b \geq 3a + \frac{1}{2} - c \right\} & \text{if } a \geq \frac{1}{2}.
\end{cases} 
\tag{4.1}
\]

\[
O_a = \begin{cases} 
  \left\{ a < b < 2a, \ c \geq 3a + \frac{1}{2} - b \right\} \\
  \cup \left\{ a < c < 2a, \ b \geq 3a + \frac{1}{2} - c \right\} & \text{if } 0 < a < \frac{1}{2}.
\end{cases} 
\tag{4.2}
\]

which represents two symmetric infinite strips bounded by \( b + c = 3a + 1/2 \) and four half-lines parallel to the coordinate axes.

By combining the methods of Fields and Ismail \[11\], Gasper \[12\] and fractional integrals with the squares of Bessel functions as kernels, two of the present authors established the following criterion.

**Theorem 4.1.** (Cho and Yun, \[8\]) For \( a > 0, b > 0, c > 0 \), put

\[
\Phi(x) = {}_1F_2 \left[ \begin{array}{c} a \\ b, c \\ \end{array} \right] \left[ -\frac{x^2}{4} \right] \quad (x > 0).
\]

Let \( P_a \) be the Newton diagram associated to \( \Lambda = \{(a + \frac{1}{2}, 2a), (2a, a + \frac{1}{2})\} \), \( O_a \) the set defined in \( (4.1) \), \( (4.2) \) and \( N_a \) the complement of \( P_a \cup O_a \) in \( \mathbb{R}^2_+ \) so that the decomposition \( \mathbb{R}^2_+ = P_a \cup O_a \cup N_a \) holds.

(i) If \( \Phi \geq 0 \), then necessarily

\[
b > a, \ c > a, \ b + c \geq 3a + \frac{1}{2}.
\tag{4.3}
\]

(ii) If \((b, c) \in P_a\), then \( \Phi \geq 0 \) and strict positivity holds unless \((b, c) \in \Lambda\).

(iii) If \((b, c) \in N_a\), then \( \Phi \) alternates in sign.

**Remark 4.1.** For the cases of nonnegativity, we follow \[8\] to introduce

\[
\mathbb{J}_a(x) = {}_0F_1 \left( \alpha + 1; -\frac{x^2}{4} \right) \quad (\alpha > -1).
\tag{4.4}
\]

11
Owing to the relation of (1.6), it is easy to see that $J_\alpha$ shares positive zeros in common with Bessel function $J_\alpha$ and its square takes the form

$$J_\alpha^2(x) = \begin{Frac}{\begin{pmatrix} \alpha + \frac{1}{2} \\ \alpha + 1, 2\alpha + 1 \end{pmatrix}}{-x^2}$$

(4.5)

when $\alpha > -1/2$. Consequently, if $(b,c) \in \Lambda$, then

$$\Phi(x) = \begin{Frac}{\begin{pmatrix} a \\ a + \frac{1}{2}, 2a \end{pmatrix}}{-x^2/4} = \begin{Frac}{\begin{pmatrix} 3a + 1/2 - b, a + a/2(b-a) \end{pmatrix}}{2(b-a)}$$

(4.6)

which is nonnegative but has infinitely many zeros on $(0, \infty)$.

Theorem 4.1 unifies many of earlier positivity results and we refer to our recent paper [7] in which it is applied to improve the results of Misiewicz and Richards [19], Buhmann [6] at the same time.

For $(b,c) \in O_a$, it is left undetermined whether positivity holds or not. We now state our main extension theorem which still does not fill out the whole of $O_a$ but covers the upper half of the rational function

$$c = a + \frac{a}{2(b-a)} \quad (b > a).$$

We shall use the letter $\Lambda$ below for the same notation as above.

**Theorem 4.2.** For $a > 0$, $b > 0$, $c > 0$, put

$$\Phi(x) = \begin{Frac}{\begin{pmatrix} a \\ b, c \end{pmatrix}}{-x^2/4} \quad (x > 0).$$

Let $P_a^*$ be the set of parameter pairs $(b,c) \in \mathbb{R}_+^2$ defined by

$$P_a^* = \left\{ (b,a,c) \geq \max \left[ 3a + \frac{1}{2} - b, a + \frac{a}{2(b-a)} \right] \right\}.$$

If $(b,c) \in P_a^* \setminus \Lambda$, then $\Phi$ is strictly positive.

**Remark 4.2.** For the sake of convenience, we illustrate Theorems 4.1, 4.2 with Figures 4.1, 4.2 for the case $a > 1/2$, $a = 1/2$, separately (the case $0 < a < 1/2$ is similar to the case $a > 1/2$). In each figure, the red-colored part indicates the improved positivity region $P_a^*$ and the grey-colored part indicates the region where positivity breaks down. The blank or white-colored parts indicate the missing region.
Figure 4.1: The improved positivity region $P_a^*$ in the case $a > \frac{1}{2}$ which includes the Newton diagram associated to $\Lambda = \{(a+1/2, 2a), (2a, a+1/2)\}$.

Figure 4.2: The improved positivity region $P_{\frac{1}{2}}^*$ which includes the Newton diagram associated to $\Lambda = \{(1, 1)\}$.

**Proof of Theorem 4.2.** In view of the difference
\[
a + \frac{a}{2(b-a)} - \left[3a + \frac{1}{2} - b\right] = \frac{(b - a - \frac{1}{2})(b - 2a)}{b-a},
\]
it is graphically obvious that the rational function \( c = a + a/2(b - a) \) lies below the line \( c = 3a + 1/2 - b \) only for \( b \in L \), where \( L \) denotes

\[
L = \{ (1 - t)(a + 1/2) + t(2a) : 0 \leq t \leq 1 \}.
\]

As it is already shown in Theorem 4.1 that \( \Phi \) is strictly positive for \((b, c) \in P_a \setminus \Lambda\), it remains to prove the positivity of \( \Phi \) in the case \((b, c) \in P_a^*\) with \( b \) lying outside the closed interval \( L \). By symmetry in \( b, c \), we may assume \( b \leq c \) and hence it suffices to deal with the case

\[
c \geq a + \frac{a}{2(b - a)}, \tag{4.7}
\]

where \( a < b < a + 1/2 \) when \( a \geq 1/2 \) or \( a < b < 2a \) when \( 0 < a < 1/2 \).

We apply Gasper’s sums of squares formula ([12], (3.1)) to write

\[
\Phi(x) = \Gamma^2(\nu + 1) \left( \frac{x}{4} \right)^{-2\nu} \left\{ J_\nu^2 \left( \frac{x}{2} \right) + \sum_{n=1}^{\infty} C(n, \nu) \frac{2n + 2\nu (2\nu + 1)_n}{n + 2\nu} \frac{n}{n!} J_{\nu+n}^2 \left( \frac{x}{2} \right) \right\} \tag{4.8}
\]

in which \( C(n, \nu) \) denotes the terminating series defined by

\[
C(n, \nu) = \, _4F_3 \left[ \begin{array}{c} -n, n + 2\nu, \nu + 1, a \\ \nu + \frac{1}{2}, b, c \end{array} \right] \tag{4.9}
\]

and \( \nu \) can be arbitrary as long as \( 2\nu \) is not a negative integer.

Due to the interlacing property on the zeros of Bessel functions \( J_\nu, J_{\nu+1} \) (see Watson [21]), the positivity of \( \Phi \) would follow instantly from formula (4.8) if \( C(n, \nu) > 0 \) for all \( n \), for instance, and \( \nu > -1/2 \).

To investigate the sign of \( C(n, \nu) \), we apply Lemma 3.1 with

\[
\alpha_1 = 2\nu, \ \alpha_2 = \nu + 1, \ \alpha_3 = a, \ \beta_1 = \nu + \frac{1}{2}, \ \beta_2 = b, \ \beta_3 = c.
\]

The Saalschützian condition (A1) of (3.1) is equivalent to the choice

\[
\nu = \frac{1}{2} \left( b + c - a - \frac{3}{2} \right). \tag{4.10}
\]
It is elementary to translate conditions (A2), (A3), (A4) of (3.1) into
\[
\begin{cases}
  c > b - a + \frac{1}{2}, & b \geq a - \frac{1}{2}, \\
  c > 3a + \frac{1}{2} - b, & b > a, \\
  c \geq a + \frac{a}{2(b-a)}.
\end{cases}
\] (4.11)

On inspecting the region determined by (4.11) in the \((b,c)\)-plane, it is immediate to find that (4.11) amounts to (4.7) subject to the restriction \(a < b < a + \frac{1}{2}\) when \(a \geq \frac{1}{2}\) or \(a < b < 2a\) when \(0 < a < \frac{1}{2}\).

By Lemma 3.1, we may conclude \(C(1, \nu) \geq 0\) and \(C(n, \nu) > 0\) for all \(n \geq 2\) with \(\nu\) chosen according to (4.10) and our proof is now complete. \(\square\)

5 Askey-Szegő problem

Returning to problem (1.1), an application of the above positivity criteria in an obvious way yields what we aimed to establish.

Theorem 5.1. For \(\alpha > -1, \beta < \alpha + 1\), put
\[
\psi(x) = \int_0^x t^{-\beta} J_\alpha(t) dt \quad (x > 0).
\]

(i) If \(\psi \geq 0\), then necessarily
\[-\alpha - 1 < \beta < \alpha + 1, \quad \beta \geq -\frac{1}{2}.
\]

(ii) Let \(\mathcal{P}^*\) be the set of \((\alpha, \beta) \in \mathbb{R}^2\) defined by
\[
\mathcal{P}^* = \left\{ \alpha > -1, \max\left[ -\frac{1}{2}, -\frac{1}{3} (\alpha + 1) \right] \leq \beta < \alpha + 1 \right\}
\]

Then \(\psi \geq 0\) for each \((\alpha, \beta) \in \mathcal{P}^*\) and strict positivity holds unless it coincides with \((1/2, -1/2)\).

Remark 5.1. In Figure 5.1, the green-colored part represents \(\mathcal{P}^*\). As it is evident pictorially on comparing with Figure 1.1, Theorem 5.1 improves Theorem A by adding the triangle with boundary lines
\[
\beta = 0, \quad \beta = -\alpha, \quad \beta = -\frac{1}{3} (\alpha + 1)
\]
as a new positivity region and by narrowing down the necessity region.
Figure 5.1: The improved positivity region for problem (1.1) in which the line $\beta = \alpha$ corresponds to Szegö’s problem (1.4).

**Proof of Theorem 5.1.** In view of (1.7), it suffices to deal with

$$
\Psi(x) = _1F_2 \left[ \begin{array}{c} \frac{\alpha-\beta+1}{2} + 1, \frac{\alpha-\beta+1}{2} + 1 \\ \alpha + 1, \frac{\alpha+\beta+1}{2} + 1 \end{array} \right] - \frac{x^2}{4}, \quad (x > 0) \tag{5.1}
$$

Under the assumption $\alpha > -1, \beta < \alpha + 1$, each parameter of $\Psi$ is positive. If $\Psi \geq 0$, then it follows from necessary condition (4.3) that

$$
\alpha + 1 > \frac{\alpha - \beta + 1}{2},
$$

$$
\frac{\alpha - \beta + 1}{2} + 1 \geq 3 \left( \frac{\alpha - \beta + 1}{2} \right) + \frac{1}{2} - (\alpha + 1),
$$

which reduces to the stated necessary condition of part (i).

To prove part (ii), we apply Theorem 4.2 with

$$
a = \frac{\alpha - \beta + 1}{2}, \quad b = \alpha + 1, \quad c = \frac{\alpha - \beta + 1}{2} + 1.
$$

Inspecting the conditions $c \geq 3a + 1/2 - b$, $c \geq a + a/2(b - a)$ for $b > a$ in terms of $\alpha, \beta$ separately, it is elementary to find the condition

$$
c \geq \max \left[ 3a + \frac{1}{2} - b, \ a + \frac{a}{2(b - a)} \right], \quad b > a,
$$
is equivalent to
\[ \beta \geq \max \left[ -\frac{1}{2}, -\frac{1}{3}(\alpha + 1) \right], \quad \beta > -\alpha - 1. \quad (5.2) \]

Combining (5.2) with the necessary condition of part (i), we deduce \( \Psi \geq 0 \) for each \( (\alpha, \beta) \in \mathcal{P}^\ast \). Regarding strict positivity, we note that the nonnegativity condition required by

\[ (b, c) \in \Lambda = \left\{ \left( a + \frac{1}{2}, 2a \right), \left( 2a, a + \frac{1}{2} \right) \right\} \]

reduces to the single case \( (\alpha, \beta) = (1/2, -1/2) \). Indeed,
\[
\Psi(x) = \mathcal{F}_2 \left( 1; 3, 2; -\frac{x^2}{4} \right) = \left[ \frac{\sin(x/2)}{x/2} \right]^2
\]

in this case, which is nonnegative but has infinitely many positive zeros.

By Theorem 4.2 we conclude \( \Psi \) is strictly positive for each \( (\alpha, \beta) \in \mathcal{P}^\ast \) unless it coincides with \( (1/2, -1/2) \) and our proof is complete.

As an immediate consequence of Theorem 5.1, we obtain the following upper and lower bounds for \( \beta(\alpha) \) and \( \bar{\alpha} \).

**Corollary 5.1.** Under the same setting as in Theorem B, we have

(i) \[ \max \left( -\alpha - 1, -\frac{1}{2} \right) < \beta(\alpha) \leq -\frac{1}{3}(\alpha + 1), \]

(ii) \[ \lim_{\alpha \to -1^+} \beta(\alpha) = 0, \quad \beta\left( \frac{1}{2} \right) = -\frac{1}{2}, \]

(iii) \[ -\frac{1}{2} < \bar{\alpha} \leq -\frac{1}{4}. \]

**Remark 5.2.** While the results are evident by Theorem B and Theorem 5.1 that \( \beta(1/2) = -1/2 \) can be verified in a simple way. Indeed, the formula

\[ J_{\frac{1}{2}}(t) = \sqrt{\frac{2t}{\pi}} \sin \frac{t}{t} \]

(see Luke \([16]\), Watson \([21]\)) implies that \( J_{\frac{1}{2}, 2} = 2\pi \) and
\[
\int_0^{2\pi} \sqrt{t} J_{\frac{1}{2}}(t) dt = \sqrt{\frac{2}{\pi}} \int_0^{2\pi} \sin t dt = 0,
\]
whence the desired value follows instantly by the uniqueness of \( \beta(\alpha) \).
Corollary 5.1 indicates that $\beta = \beta(\alpha)$, $-1 < \alpha \leq 1/2$, is a smooth curve joining $(-1, 0)$, $(1/2, -1/2)$ which lies in the triangle determined by

$$\beta = -\alpha - 1, \quad \beta = -1/2, \quad \beta = -(\alpha + 1)/3.$$ 

In [3], Askey and Steinig gave a list of numerical approximations for $\beta(\alpha)$. To get an insight into how accurate or informative the above upper bound would be, we compare it with their list as follows.

| $\alpha$ | $\beta(\alpha)$ | $-\frac{1}{3}(\alpha + 1)$ |
|----------|------------------|-----------------------------|
| -0.5     | -0.1915562       | -0.1666667                  |
| -0.4     | -0.2259427       | -0.2000000                  |
| -0.3     | -0.2593436       | -0.2333333                  |
| -0.2     | -0.2918541       | -0.2666667                  |
| -0.1     | -0.3235531       | -0.3000000                  |
| 0        | -0.3545096       | -0.3333333                  |
| 0.1      | -0.3847832       | -0.3666667                  |
| 0.2      | -0.4144258       | -0.4000000                  |
| 0.3      | -0.4434834       | -0.4333333                  |
| 0.4      | -0.4719960       | -0.4666667                  |

Regarding the approximated values as true ones, these comparisons show that $\beta(\alpha)$ lies within distance 0.026 from $-(\alpha + 1)/3$ and the error increases up to certain point near $\alpha = -0.3$ and then decreases to zero.

On the other hand, we also point out that G. Szegö [10] approximated $\bar{\alpha} \approx -0.2693885$, whereas our upper bound of $\bar{\alpha}$ is $-0.25$.

6 Gasper’s extensions

As a generalization of (1.1), we consider the problem of determining parameters $\alpha, \beta, \gamma$ for the inequality

$$\int_0^x (x^2 - t^2)^\gamma t^{-\beta} J_\alpha(t) dt \geq 0 \quad (x > 0), \quad (6.1)$$

which reduces to problem (1.1) in the special case $\gamma = 0$. 

18
By integrating termwise, it is plain to evaluate

\[
\int_{0}^{x} (x^2 - t^2)^\gamma t^{-\beta} J_\alpha(t) dt = \frac{B(\gamma + 1, \frac{\alpha-\beta+1}{2})}{2^{\alpha+1}\Gamma(\alpha + 1)} x^{\alpha-\beta+2\gamma+1} \\
\times {}_{1}F_{2}\left[\begin{array}{c}
\alpha + 1, \frac{\alpha-\beta+1}{2} + \gamma + 1 \\mid -\frac{x^2}{4}
\end{array}\right]
\]

subject to the condition \( \alpha > -1, \gamma > -1, \beta < \alpha + 1 \), where \( B \) denotes the usual Euler’s beta function. In analogy with (1.1), hence, problem (6.1) is equivalent to the positivity question on the \( {}_{1}F_{2} \) generalized hypergeometric function defined on the right side of (6.2).

In [12], Gasper employed the sums of squares method and an interpolation argument involving fractional integrals to prove that (6.1) holds with strict positivity for each \( (\alpha, \beta) \in \mathcal{S}_\gamma \setminus \{ (\gamma + 1/2, -\gamma - 1/2) \} \), where

\[
\mathcal{S}_\gamma = \left\{ \alpha \geq \gamma + \frac{1}{2}, \alpha - 2\gamma - 1 \leq \beta < \alpha + 1 \right\}
\]

in the case \(-1 < \gamma \leq -1/2\) and

\[
\mathcal{S}_\gamma = \left\{ \alpha > -1, 0 \leq \beta < \alpha + 1 \right\} \\
\cup \left\{ \alpha \geq \gamma + \frac{1}{2}, -\left(\gamma + \frac{1}{2}\right) \leq \beta \leq 0 \right\}
\]

in the case \(\gamma > -1/2\) (see Figures 6.1, 6.2 below).

Our purpose here is to improve Gasper’s result as follows.

**Theorem 6.1.** Let \( \alpha > -1, \gamma > -1, \beta < \alpha + 1 \).

(i) If (6.1) holds, then necessarily

\[
\beta \geq -\left(\gamma + \frac{1}{2}\right), \quad -\alpha - 1 < \beta < \alpha + 1.
\]

(ii) For each \( \gamma > -1 \), let \( \mathcal{S}_\gamma^* \) be the set of \( (\alpha, \beta) \in \mathbb{R}^2 \) defined by

\[
\mathcal{S}_\gamma^* = \left\{ \alpha > -1, \max \left[ -\left(\gamma + \frac{1}{2}\right), -\frac{2\gamma + 1}{2\gamma + 3}(\alpha + 1) \right] \leq \beta < \alpha + 1 \right\}.
\]

If \( (\alpha, \beta) \in \mathcal{S}_\gamma^* \), then (6.1) holds with strict positivity unless

\[
\alpha = \gamma + \frac{1}{2}, \beta = -\left(\gamma + \frac{1}{2}\right) \quad \text{or} \quad \gamma = -\frac{1}{2}, \beta = 0.
\]
Proof of Theorem 6.1. In view of (6.2), it suffices to deal with

\[ \Sigma(x) = \, _1F_2 \left[ \begin{array}{c|c} \frac{\alpha - \beta + 1}{2} & \frac{\alpha - \beta + 1}{2} + \gamma + 1 \\ \hline \alpha + 1, & -\frac{x^2}{4} \end{array} \right] \quad (x > 0). \] (6.5)

On setting

\[ a = \frac{\alpha - \beta + 1}{2}, \quad b = \alpha + 1, \quad c = \frac{\alpha - \beta + 1}{2} + \gamma + 1 \]

and applying the necessity part of Theorem 4.1, Theorem 4.2 in the same way as in the proof of Theorem 5.1, it is straightforward to verify (i), (ii).

As for the cases of nonnegativity, we note from (4.6) of Remark 4.1 that if \( \alpha = \gamma + 1/2, \beta = -(\gamma + 1/2), \gamma > -1 \), then

\[ \Sigma(x) = \, _1F_2 \left[ \begin{array}{c} \frac{\gamma + 1}{2} \\ \gamma + \frac{2}{3}, 2(\gamma + 1) \end{array} \right] = j_{\gamma+\frac{1}{2}} \left( \frac{x}{2} \right). \] (6.6)

On the other hand, if \( \alpha > -1, \beta = 0, \gamma = -1/2 \), then

\[ \Sigma(x) = \, _1F_2 \left[ \begin{array}{c} \frac{\alpha + 1}{2} \\ \alpha + 1, \frac{\alpha + 2}{2} \end{array} \right] = j_{\frac{\alpha+1}{2}} \left( \frac{x}{2} \right). \] (6.7)

Both identities show \( \Sigma \geq 0 \) with infinitely many positive zeros. \(\square\)

Remark 6.1. As for the missing ranges, we point out the following:

- In the case \( \gamma > -1/2 \), as shown in Figure 6.1, Theorem 6.1 leaves the triangle formed by the boundary lines

\[ \beta = -\alpha - 1, \quad \beta = -(\gamma + 1/2), \quad \beta = -\frac{2\gamma + 1}{2\gamma + 3}(\alpha + 1) \]

and it is an open question if it is possible to give a necessary and sufficient condition in terms of certain transcendental root \( \beta_\gamma(\alpha) \) in an analogous manner with the case \( \gamma = 0 \).

- In the case \( \gamma = -1/2 \), problem (6.1) is completely resolved in the sense that it holds if and only if \( \alpha > -1, 0 \leq \beta < \alpha + 1 \).

- In the case \( -1 < \gamma < -1/2 \), as shown in Figure 6.2, Theorem 6.1 leaves the infinite sector defined by

\[ \alpha > \gamma + 1/2, \quad -(\gamma + 1/2) \leq \beta < -\frac{2\gamma + 1}{2\gamma + 3}(\alpha + 1). \]
Figure 6.1: The improved positivity region for problem (6.1) in the case $\gamma > -1/2$, where the yellow-colored part represents Gasper's region.

Figure 6.2: The improved positivity region for problem (6.1) in the case $-1 < \gamma < -1/2$, where the yellow-colored part represents Gasper's region.
