CLT FOR THE CAPACITY OF THE RANGE OF STABLE RANDOM WALKS

WOJCIECH CYGAN, NIKOLA SANDRIĆ, AND STJEPAN ŠEBEK

ABSTRACT. In this article, we establish a central limit theorem for the capacity of the range process for a class of $d$-dimensional symmetric $\alpha$-stable random walks with the index satisfying $d \geq 3\alpha$. Our approach is based on controlling the limit behavior of the variance of the capacity of the range process which then allows us to apply the Lindeberg-Feller theorem.

1. INTRODUCTION

Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space, and let $\{X_i\}_{i \in \mathbb{N}}$ be a sequence of i.i.d. $\mathbb{Z}^d$-valued random variables defined on $(\Omega, \mathcal{F}, \mathbb{P})$, where $d \geq 1$ and $\mathbb{Z}^d$ stands for the $d$-dimensional integer lattice. For $x \in \mathbb{Z}^d$ define $S_0 = x$ and $S_n = S_{n-1} + X_n$, $n \geq 1$. The stochastic process $\{S_n\}_{n \geq 0}$ is called a $\mathbb{Z}^d$-valued random walk starting from $x$.

Throughout the article we will often rely on the Markovian nature of $\{S_n\}_{n \geq 0}$, therefore we need to allow arbitrary initial conditions of the underlying probability measure. For this purpose we redefine the probability space in the following way. Put $\tilde{\Omega} = \mathbb{Z}^d \times \Omega$, $\tilde{\mathcal{F}} = \mathcal{P}(\mathbb{Z}^d) \otimes \mathcal{F}$, and $\mathbb{P}_x = \delta_x \times \mathbb{P}$ for $x \in \mathbb{Z}^d$. A random variable $X$ on $(\Omega, \mathcal{F}, \mathbb{P})$ is extended automatically to $(\tilde{\Omega}, \tilde{\mathcal{F}}; \{\mathbb{P}_x\}_{x \in \mathbb{Z}^d})$ by the rule $X((x, \omega)) = X(\omega)$ for $x \in \mathbb{Z}^d$ and $\omega \in \Omega$. Further, define $S_0 : \tilde{\Omega} \to \mathbb{Z}^d$ by $S_0((x, \omega)) = x$ for $x \in \mathbb{Z}^d$ and $\omega \in \Omega$. Clearly, $\mathbb{P}_x(\tilde{S}_0 = x) = 1$, and for each $x \in \mathbb{Z}^d$ the process $\{S_n\}_{n \geq 0}$ is a $\mathbb{Z}^d$-valued random walk on $(\tilde{\Omega}, \tilde{\mathcal{F}}, \mathbb{P}_x)$ starting from $x$. Also, it is a (strong) Markov process (with respect to the corresponding natural filtration). Observe that the corresponding transition probabilities are given by

$$p_n(x, y) = \mathbb{P}_x(S_n = y) = \mathbb{P}_0(S_n = y - x), \quad n \geq 0, \ x, y \in \mathbb{Z}^d.$$ 

From the above relation we immediately see that there are functions $\{p_n\}_{n \geq 0}$ such that $p_n(y - x) = p_n(x, y) = p_n(0, y - x)$, $n \geq 0$, $x, y \in \mathbb{R}^d$. Also, for notational simplicity we write $(\Omega, \tilde{\mathcal{F}}; \{\mathbb{P}_x\}_{x \in \mathbb{Z}^d})$ instead of $(\tilde{\Omega}, \tilde{\mathcal{F}}, \{\mathbb{P}_x\}_{x \in \mathbb{Z}^d})$, and when $x = 0$ we suppress the index $0$ and write $\tilde{\mathbb{P}}$ instead of $\mathbb{P}_0$.

The main aim of this article is to establish a central limit theorem for the capacity of the range process of $\{S_n\}_{n \geq 0}$. Recall that the range process $\{\mathcal{R}_n\}_{n \geq 0}$ is defined as the random set

$$\mathcal{R}_n = \{S_0, \ldots, S_n\}, \quad n \geq 0.$$ 

For $1 \leq m \leq n$ we use notation $\mathcal{R}[m, n] = \mathcal{R}_n \setminus \mathcal{R}_{m-1}$. The capacity of a set $A \subseteq \mathbb{Z}^d$ (with respect to $\{S_n\}_{n \geq 0}$) is defined as

$$\text{Cap}(A) = \sum_{x \in A} \mathbb{P}_x(T^+_A = \infty).$$

2010 Mathematics Subject Classification. 60F05, 60G50, 60G52.

Key words and phrases. capacity, central limit theorem, strong transience, the range of a random walk.
Here, $T^+_A$ denotes the first return time of $\{S_n\}_{n\geq 0}$ to the set $A$, that is,

$$T^+_A = \inf \{n \geq 1 : S_n \in A\}.$$

Also, when $A = \{x\}$, $x \in \mathbb{Z}^d$, we write $T^+_x$ instead of $T^+_\{x\}$. We are interested in the long-time behaviour of the process $\{C_n\}_{n\geq 0}$ defined as

$$C_n = \text{Cap}(R_n).$$

Before stating the main result, we introduce and discuss the assumptions which we impose on the random walk $\{S_n\}_{n\geq 0}$.

(A1) $\{S_n\}_{n\geq 0}$ is aperiodic, that is, the smallest additive subgroup generated by the set supp $p_1 = \{x \in \mathbb{Z}^d : p_1(x) > 0\}$ is equal to $\mathbb{Z}^d$.

(A2) $\{S_n\}_{n\geq 0}$ is symmetric and strongly transient.

(A3) $\{S_n\}_{n\geq 0}$ belongs to the domain of attraction of a non-degenerate $\alpha$-stable random law with $0 < \alpha \leq 2$, meaning that there exists a regularly varying function $b(x)$ with index $1/\alpha$ such that

$$\frac{S_n}{b(n)} \overset{(d)}{\to} X_\alpha^*,$$

where $X_\alpha$ is an $\alpha$-stable random variable on $\mathbb{R}^d$ and $(d)$ stands for the convergence in distribution.

(A4) $\{S_n\}_{n\geq 0}$ admits one-step loops, that is, $p = p_1(0) > 0$.

Let us remark that assumption (A1) is not restrictive in any sense. Namely, if $\{S_n\}_{n\geq 0}$ is not aperiodic, we can then perform our analysis (and obtain the same results) on the smallest additive subgroup of $\mathbb{Z}^d$ generated by supp $p_1$ (see [20, pp 20]).

To discuss (A2) and (A3) let us denote by

$$G(x, y) = \sum_{n\geq 0} p_n(y - x), \quad x, y \in \mathbb{Z}^d$$

the Green function of $\{S_n\}_{n\geq 0}$. Due to the spatial homogeneity of $\{S_n\}_{n\geq 0}$, we sometimes write $G(y - x)$ instead of $G(x, y)$. Recall now that $\{S_n\}_{n\geq 0}$ is called transient if $G(0) < \infty$; otherwise it is called recurrent. It is well known that every random walk is either transient or recurrent. Analogously, a transient random walk $\{S_n\}_{n\geq 0}$ is called strongly transient if $\sum_{n\geq 1} n p_n(0) < \infty$; otherwise it is called weakly transient. Again, it is known that every transient random walk is either strongly or weakly transient (see [18]). Under (A3), $\{S_n\}_{n\geq 0}$ is transient if $d > \alpha$ and strongly transient if $d > 2\alpha$ (see [18, Theorem 3.4], cf. also [21, Theorem 7]). The notion of strong transience was first introduced in [17] for Markov chains and was later used in [11] in the context of the limit behavior of the range of random walks. Actually, in [11] a slightly different definition of strong (weak) transience has been used: a transient random walk $\{S_n\}_{n\geq 0}$ is called strongly transient if $\sum_{n\geq 1} n P(T^+_0 = n) < \infty$; otherwise it is called weakly transient. For reader’s convenience we show that these two definitions are equivalent. Indeed, starting from the following classical identity (see [20])

$$p_k(0) = \sum_{j=1}^k P(T^+_0 = j) p_{k-j}(0), \quad k \geq 1,$$
we easily obtain that
\[
\sum_{n=1}^{\infty} n P_n(0) \left(1 - \sum_{j=1}^{\infty} P(T_0^+ = j)\right) = G(0) \sum_{n=1}^{\infty} n P(T_0^+ = n),
\]
and whence both series must converge simultaneously. It is a well-known fact that the condition \(G(0) < \infty\) forces \(P(T_0^+ < \infty) = \sum_{n=1}^{\infty} P(T_0^+ = n) < 1\).

We remark that the strong transience assumption is very natural in this context. Namely, it ensures that the range process \(\{R_n\}_{n \geq 0}\) grows fast enough which allows us to conclude that the limiting distribution in Theorem 1.1 below is not degenerated, in other words, the constant \(\sigma_d\) does not vanish.

Finally, assumption (A4) is of technical nature only. By using a random time-change argument and loop decomposition technique, it allows us to conclude that the limit in (1.1) exists and it is not degenerated.

A natural way to construct a random walk that satisfies our assumptions (A1)-(A4) is to employ a recently introduced method of discrete subordination (see [5]). To be more precise, let us consider the simple random walk in \(\mathbb{Z}\) that we denote by \(\{Z_n\}_{n \geq 0}\). Further, let \(\{\eta_n\}_{n \geq 0}\) be an increasing random walk in \(\mathbb{Z}\) starting from 0 that is independent of \(\{Z_n\}_{n \geq 0}\), and which is uniquely determined by the following relation
\[
\mathbb{E}[e^{-\lambda \eta_n}] = 1 - \psi(1 - e^{-\lambda}).
\]
Here \(\psi(\lambda)\) is a Bernstein function (see [19]) such that \(\psi(0) = 0\) and \(\psi(1) = 1\). We then define the subordinate random walk as \(S_n = Z_{\eta_n}, n \geq 0\). Such a random walk is aperiodic and symmetric. Moreover, it satisfies (A3) with index \(0 < \alpha \leq 2\) if and only if the function \(\psi(\lambda)\) is regularly varying at zero with index \(\alpha/2\) (see [16] and [4]). For instance, one can take \(\psi(\lambda) = \lambda^{\alpha/2}\). More general examples of random walks satisfying assumption (A3) may be found in [22].

We now state the main result of the article.

**Theorem 1.1.** Assume (A1)-(A4) and \(d \geq 3\alpha\). Then, there is a constant \(\sigma_d > 0\) such that
\[
\frac{C_n - \mathbb{E}[C_n]}{\sqrt{n}} \xrightarrow{n \to \infty} \sigma_d \mathcal{N}(0, 1),
\]
where \(\mathcal{N}(0, 1)\) stands for the standard normal distribution.

**Outline of the proof.** Let us briefly explain the main steps of the proof. We follow the path of [2] but with a number of different ideas and approaches. The proof itself follows from the Lindeberg-Feller central limit theorem [8, Theorem 3.4.5] which requires a certain control of the asymptotic behavior (arithmetic mean and tail behavior) of \(\{\text{Var}(C_n)\}_{n \geq 0}\). As the key results in this direction we show that

(i) the sequence \(\{\text{Var}(C_n)/n\}_{n \geq 1}\) converges (see Lemma 4.3), and
(ii) the limit is strictly positive (see Lemma 5.3).

With this in hands and a more general form of the following capacity decomposition
\[
C_m + \text{Cap}(\mathcal{R}[m, n]) - 2G(\mathcal{R}_m, \mathcal{R}[m, n]) \leq C_n - C_m + \text{Cap}(\mathcal{R}[m, n]), \quad 0 \leq m \leq n,
\]
which was obtained in [2, Corollary 2.1], we conclude that the left hand side in (1.1) converges in distribution to a zero-mean normal law with variance \(\sigma_d\) which is exactly the limit of \(\{\text{Var}(C_n)/n\}_{n \geq 1}\). Here
\[
G(\mathcal{R}_m, \mathcal{R}[m, n]) = \sum_{x \in \mathcal{R}_m, y \in \mathcal{R}[m, n]} G(x, y), \quad 0 \leq m \leq n.
\]
is the error term which is the main object to be studied in order to get estimates of the sequence $\{\text{Var}(C_n)\}_{n \geq 0}$.

The proof of step (i) follows the approach from [2] which bases on the estimates of the moments of $\{C_n\}_{n \geq 0}$ extracted from [14], combined with an application of Hammersley’s lemma (see [10]). Also, this is the place in the article where the restriction to $d \geq 3a$ plays a key role.

To conclude step (ii) we require (A4). The proof is based on a random time-change argument and loop decomposition technique (see Subsection 5).

**Literature overview and related results.** The study on the range process $\{R_n\}_{n \geq 0}$ of a $\mathbb{Z}^d$-valued random walk $\{S_n\}_{n \geq 0}$ has a long history. A pioneering work is due to Dvoretzky and Erdős [9] where they obtained a law of large numbers for $\{\#R_n\}_{n \geq 0}$ when $\{S_n\}_{n \geq 0}$ is the simple random walk and $d \geq 2$. Here, $\#R_n$ denotes the cardinality of $R_n$. The result was later extended by Spitzer [20] for an arbitrary random walk in $d \geq 1$. Central limit theorem for $\{\#R_n\}_{n \geq 0}$ was obtained by Jain and Orey [11] when $\{S_n\}_{n \geq 0}$ is strongly transient. Le Gall and Rosen [15] were the first who considered the strong law of large numbers and the central limit theorem for $\{\#R_n\}_{n \geq 0}$ in the case when $\{S_n\}_{n \geq 0}$ is a stable aperiodic random walk, that is, it satisfies (A1) and (A3). On the other hand, the first results on the long-time behavior of the capacity process $\{C_n\}_{n \geq 0}$ are due to Jain and Orey [11] where they obtained a version of the strong law of large numbers for any transient random walk. Very recently Asselah, Schapira and Sousi [2] proved a central limit theorem for $\{C_n\}_{n \geq 0}$ for the simple random walk in $d \geq 6$. Versions of a law of large numbers and central limit theorem in the case $d = 4$ were proved by the same authors in [3], whereas Asselah and Schapira [1] also showed the large deviation principle for $d \geq 5$.

The aim of this article is to obtain a central limit theorem for the capacity of the range process for a class of $a$-stable strongly transient random walks in dimensions $d \geq 3a$. To the best of our knowledge this is the first result in this direction dealing with random walks that do not have finite second moment. Our motivation comes from the article by Le Gall and Rosen [15], and approach developed by Asselah, Schapira and Sousi [2]. A type of the limit behaviour of the sequence $\{C_n\}_{n \geq 0}$ depends on the value of the ratio $d/a$. The study of the case when $d/a < 3$ is an ongoing project and it is postponed to a follow-up paper.

2. ON THE SLLN FOR $\{C_n\}_{n \geq 0}$

In this section, we prove that under (A2) the sequence $\{C_n\}_{n \geq 0}$ satisfies a (version of) strong law of large numbers with strictly positive limit. This result will be crucial in showing that the limit in (1.1) is non-degenerate (see Section 5). Recall first that for any transient random walk on $\mathbb{Z}^d$ it holds that the corresponding capacity process $\{C_n\}_{n \geq 0}$ satisfies

$$\lim_{n \to \infty} \frac{C_n}{n} = \mu_d \quad \mathbb{P}\text{-a.s.} \quad (2.1)$$

(see [11, Theorem 2]). In the rest of this section we show that under (A2) the constant $\mu_d$ is necessarily strictly positive. We start with the following auxiliary lemma. Recall that for $A, B \subseteq \mathbb{Z}^d$ the quantity $G(A, B)$ is defined as

$$G(A, B) = \sum_{x \in A, y \in B} G(x, y).$$
Lemma 2.1. Assume (A2). Then there is a constant $C > 0$ such that
\[ \mathbb{E} \left[ G(R_n, R_n) \right] \leq Cn, \quad n \geq 1. \]

Proof. We have
\[
\mathbb{E} \left[ G(R_n, R_n) \right] = \mathbb{E} \left[ \sum_{k,l=1}^{n} G(S_{k}, S_{l}) \right] = \mathbb{E} \left[ \sum_{k=1}^{n} G(S_{0}) + \sum_{k=1}^{n} \sum_{l \neq k} G(S_{k-l}) \right]
\leq \mathbb{E} \left[ nG(0) + 2 \sum_{k=1}^{n} \sum_{l=1}^{n} G(S_{l}) \right] \leq 2G(0)n \left( 1 + \sum_{l=1}^{n} \mathbb{E}[G(S_{l})] \right)
= 2G(0)n \left( 1 + \sum_{l=1}^{n} \sum_{x \in \mathbb{Z}^{d}} \sum_{k=0}^{\infty} p_{k}(0, x)p_{l}(x, 0) \right)
= 2G(0)n \left( 1 + \sum_{l=1}^{n} \sum_{k=0}^{\infty} p_{k+l}(0) \right) \leq 2G(0)n \left( 1 + \sum_{l=1}^{\infty} \sum_{k=l}^{\infty} p_{k}(0) \right)
= 2G(0)n \left( 1 + \sum_{k=1}^{\infty} kp_{k}(0) \right) \leq Cn,
\]
where the last inequality follows from (A2).

We now show that 0 cannot be an accumulation point of \( \{E[C_n]/n\}_{n \geq 1} \).

Proposition 2.2. Assume (A2). Then there is a constant $c > 0$ such that
\[
\liminf_{n \to \infty} \frac{E[C_n]}{n} \geq c.
\]

Proof: For fixed $n \geq 1$ we consider the following (random) probability measure defined on $\mathbb{Z}^{d}$
\[
\nu_{n}(x) = \frac{1}{n} \sum_{k=1}^{n} \delta_{S_{k}}(x).
\]
Clearly, $\text{supp} \nu_{n} = R[1, n]$. According to [12, Lemma 2.3], for symmetric random walks the capacity of a set $A \subseteq \mathbb{Z}^{d}$ has the following representation
\[
\text{Cap}(A) = \frac{1}{\inf_{\nu} \sum_{x,y \in A} G(x, y)\nu(x)\nu(y)},
\]
where the infimum is taken over all probability measures on $\mathbb{Z}^{d}$ with $\text{supp} \nu \subseteq A$. By setting
\[
J(\nu_{n}) = \sum_{x,y \in R_{n}} G(x, y)\nu_{n}(x)\nu_{n}(y) = \frac{1}{n^{2}} G(R_{n}, R_{n}),
\]
we obtain $C_{n} \leq (J(\nu_{n}))^{-1}$. Finally, by Jensen’s inequality we have that
\[
\mathbb{E}[C_{n}] \geq \left( \mathbb{E}[J(\nu_{n})] \right)^{-1},
\]
which together with Lemma 2.1 proves the assertion.
As a direct consequence of (2.1) and Proposition 2.2 we conclude strict positivity of the constant \( \mu_d \).

**Corollary 2.3.** Under (A2) it holds that \( \mu_d > 0 \).

### 3. Error Term Estimates

The goal of this section is to obtain estimates of the error term which is of the form (1.2). This will be crucial in the analysis of the sequence \( \{ \text{Var}(C_n) \}_{n \geq 0} \). In the sequel we assume (A3). Recall that the function \( b(x) \) is necessarily of the following form

\[
b(x) = x^{1/a} \ell(x), \quad x \geq 0,
\]

where \( \ell(x) \) is a slowly varying function. Without loss of generality we may assume that \( b(x) \) is continuous, increasing and \( b(0) = 0 \) (see [6]). If, in addition, (A1) holds true, then by [15, Proposition 2.4.] there exists a constant \( C > 0 \) such that for any \( n \geq 0 \) and \( x \in \mathbb{Z}^d \),

\[
p_n(x) \leq C(b(n))^{-d}.
\]

Recall that \( \{ S_n \}_{n \geq 0} \) is transient if \( d > \alpha \) and it is strongly transient if \( d > 2\alpha \). Further, for \( n \geq 0 \) we write \( G_n(x, y) \) for the Green function up to time \( n \), that is,

\[
G_n(x, y) = \sum_{k=0}^{n} p_k(x, y), \quad x, y \in \mathbb{Z}^d.
\]

Also, similarly as before, we use the notation \( G_n(x) = G_n(0, x), x \in \mathbb{Z}^d \). We start with the following auxiliary lemma.

**Lemma 3.1.** Assume (A1)-(A3). Then there exists a constant \( C > 0 \) such that for all \( n \geq 1 \) and all \( a \in \mathbb{Z}^d \),

\[
\sum_{x, y \in \mathbb{Z}^d} G_n(x)G_n(y)G(y - x + a) \leq Ch_\alpha(n),
\]

where \( h_\alpha(n) \) is given by

\[
h_\alpha(n) = \begin{cases} 
1, & d/\alpha > 3, \\
\sum_{k=1}^{n} k^{-1} \ell(k)^{-d}, & d/\alpha = 3, \\
n^2(b(n))^{-d}, & 2 < d/\alpha < 3.
\end{cases}
\]

Observe that the function \( n \mapsto \sum_{k=1}^{n} k^{-1} \ell(k)^{-d} \) is non-decreasing and slowly varying.

**Proof.** By (3.1) we have that for all \( k, j \geq 0 \),

\[
\sum_{x, y \in \mathbb{Z}^d} p_k(0, x)p_j(0, y)G(x, y + a) = \sum_{i=0}^{\infty} \sum_{x, y \in \mathbb{Z}^d} p_k(0, x)p_j(a, y + a)p_j(x, y + a)
\]

\[
= \sum_{i=0}^{\infty} \sum_{x, y \in \mathbb{Z}^d} p_k(0, x)p_j(x, y + a)p_j(y + a, a)
\]

\[
= \sum_{i=0}^{\infty} p_{k+i+j}(0, a) \leq c_1 \sum_{i=k+j}^{\infty} b(i)^{-d}
\]

\[
\leq c_2(j + k) b(j + k)^{-d},
\]
where the last inequality follows from [6, Proposition 1.5.10]. Summing over \( j \) from the set \( \{0, 1, \ldots, n\} \) yields

\[
\sum_{x,y \in \mathbb{Z}^d} p_k(0,x)G_n(y)G(x,y+a) \leq c_2 \sum_{j=0}^{n} (j+k)b(j+k)^{-d} \leq c_3 k^2 b(k)^{-d},
\]

where we again used [6, Proposition 1.5.10] together with the fact that \( d > 2\alpha \). Summing over \( k = 0, 1, \ldots, n \) gives

\[
\sum_{x,y \in \mathbb{Z}^d} G_n(x)G_n(y)G(x,y+a) \leq c_3 \sum_{k=0}^{n} k^2 b(k)^{-d}.
\]

For \( d > 3\alpha \) we can again apply [6, Proposition 1.5.10] to get

\[
\sum_{k=1}^{\infty} k^2 b(k)^{-d} < \infty.
\]

Hence, for \( d > 3\alpha \) we set \( h_d(x) = 1 \). If \( d = 3\alpha \) we obtain

\[
\sum_{k=1}^{n} k^2 b(k)^{-d} = \sum_{k=1}^{n} k^{-1} \varepsilon(k)^{-d},
\]

as desired. We mention that slow variation of \( n \mapsto \sum_{k=1}^{n} k^{-1} \varepsilon(k)^{-d} \) follows from [15, Lemma 2.2]. Finally, for \( 2 < d/\alpha < 3 \) we apply [6, Theorem 1.5.11] to get

\[
\sum_{k=1}^{n} k^2 b(k)^{-d} \leq c_d n^3 b(n)^{-d}, \quad n \geq 1,
\]

what finishes the proof. \( \Box \)

We next obtain estimates of the error term. Let us remark here that a similar result has been obtained in [2, Lemma 3.2] for the simple random walk only. We give an alternative proof of this result which relies on the Markovian structure of random walks and was motivated by techniques that were applied to estimate moments of intersection times for random walks, cf. [7] and [13]. Our approach is valid for all random walks satisfying (A1)-(A3).

**Lemma 3.2.** Assume (A1)-(A3). Let \( \{S'_n\}_{n \geq 0} \) be an independent copy of \( \{S_n\}_{n \geq 0} \) and denote the corresponding range process by \( \{R'_n\}_{n \geq 0} \). Then, for all \( k, n \geq 1 \) we have that

\[
\mathbb{E} \left[ \left( G(R_n, R'_n) \right)^k \right] \leq C h_d(n)^k,
\]

where \( C > 0 \) is a constant that depends on \( k \), and \( h_d(n) \) is defined in Lemma 3.1.

**Proof.** Let us consider the hitting times \( T_x = \inf\{n \geq 0 : S_n = x\}, \ x \in \mathbb{Z}^d \). It then holds

\[
\mathbb{E} \left[ G(R_n, R'_n) \right] = \sum_{x,y \in \mathbb{Z}^d} \mathbb{P}(T_x \leq n) \mathbb{P}(T_y \leq n) G(x,y).
\]

Since \( \mathbb{P}(T_x \leq n) \leq G_n(x) \), for \( k = 1 \) we conclude the result in view of Lemma 3.1. For \( k > 1 \) we proceed as follows. We first observe that

\[
\mathbb{E} \left[ \left( G(R_n, R'_n) \right)^k \right] = \sum_{x_1, \ldots, x_k \in \mathbb{Z}^d} \sum_{y_1, \ldots, y_k \in \mathbb{Z}^d} \mathbb{E} \left[ \prod_{i=1}^{k} 1_{\{x_i \in R_n\}} \right] \mathbb{E} \left[ \prod_{i=1}^{k} 1_{\{y_i \in R_n\}} \right] \prod_{i=1}^{k} G(x_i, y_i).
\]
For simplicity we use notation
\[ r_n(x_1, \ldots, x_j) = \mathbb{P}(T_{x_1} \leq \ldots \leq T_{x_j} \leq n), \quad j \geq 1, \ x_1, \ldots, x_j \in \mathbb{Z}^d. \]
We clearly have
\[
\mathbb{E} \left[ \prod_{i=1}^{k} 1_{\{x_i \in R_n\}} \right] \leq \sum_{\pi \in \Pi(k)} r_n(x_{\pi(1)}, \ldots, x_{\pi(k)}),
\]
where \( \Pi(k) \) is the set of all permutations of the set \( \{1, \ldots, k\} \). Hence
\[
\sum_{x_1, \ldots, x_k \in \mathbb{Z}^d} \mathbb{E} \left[ \prod_{i=1}^{k} 1_{\{x_i \in R_n\}} \right] \leq k! \sum_{x_1, \ldots, x_k \in \mathbb{Z}^d} r_n(x_1, \ldots, x_k).
\]
Notice that the strong Markov property employed at time \( T_{x_{k-1}} \) implies that
\[ r_n(x_1, \ldots, x_k) \leq r_n(x_1, \ldots, x_{k-1}) \mathbb{P}_{x_{k-1}}(T_{x_k} \leq n). \]
We thus obtain
\[
\mathbb{E} \left[ (G(R_n, R_n'))^k \right] \leq (k!)^2 \sum_{x_1, \ldots, x_{k-1} \in \mathbb{Z}^d} \sum_{y_1, \ldots, y_{k-1} \in \mathbb{Z}^d} r_n(x_1, \ldots, x_{k-1}) r_n(y_1, \ldots, y_{k-1}) \prod_{i=1}^{k-1} G(x_i, y_i) \times \sum_{x_k, y_k \in \mathbb{Z}^d} \mathbb{P}_{x_{k-1}}(T_{x_k} \leq n) \mathbb{P}_{y_{k-1}}(T_{y_k} \leq n) G(x_k, y_k).
\]
For the last term we have
\[
\sum_{x_k, y_k \in \mathbb{Z}^d} \mathbb{P}_{x_{k-1}}(T_{x_k} \leq n) \mathbb{P}_{y_{k-1}}(T_{y_k} \leq n) G(x_k, y_k) \leq \sum_{x_k, y_k \in \mathbb{Z}^d} G_n(x_{k-1}, x_k) G_n(y_{k-1}, y_k) G(x_k, y_k)
\]
and, by Lemma 3.1, the last sum is bounded by a constant times \( h_j(n) \). By repeating the same argument \( k \) times we get the result. \( \square \)

4. Variance Estimates

In this section, we show that the limit of \( \{\text{Var}(C_n)/n\}_{n \geq 1} \) always exists. We follow the approach from [2, Lemma 3.5]. The proof is based on the following two results which we state for reader’s convenience. The first one is Hammersley’s lemma.

**Lemma 4.1** ([10, Theorem 2]). Let \( \{a_n\}_{n \geq 1} \) and \( \{b_n\}_{n \geq 1} \) be sequences of real numbers satisfying
\[ a_{n+m} \leq a_n + a_m + b_{n+m}, \quad n, m \geq 1. \]
If \( \{b_n\}_{n \geq 1} \) is non-decreasing and
\[ \sum_{n=1}^{\infty} \frac{b_n}{n^2} < \infty, \]
then \( \{a_n/n\}_{n \geq 1} \) converges to a finite limit.

The second is the capacity decomposition formula discussed in the introduction.

**Lemma 4.2** ([20, Proposition 25.11] and [2, Proposition 1.2]). Let \( A, B \subset \mathbb{Z}^d \) be finite. Then
\[ \text{Cap}(A) + \text{Cap}(B) - 2G(A, B) \leq \text{Cap}(A \cup B) \leq \text{Cap}(A) + \text{Cap}(B) - \text{Cap}(A \cap B). \]

**Lemma 4.3.** Assume (A1)-(A3) and \( d \geq 3\alpha \). Then the sequence \( \{\text{Var}(C_n)/n\}_{n \geq 1} \) converges to \( \sigma_d \geq 0 \).
Proof. Let \( n, m \geq 1 \) be arbitrary. Due to space homogeneity of the capacity, that is, \( \text{Cap}(A) = \text{Cap}(A + x), \ x \in \mathbb{Z}^d, \ A \subseteq \mathbb{Z}^d \), we have that

\[
C_{n+m} = \text{Cap}(R_{n+m} - S_n) = \text{Cap}(\{S_0 - S_n, \ldots, S_n - S_n\} \cup \{S_n - S_n, \ldots, S_{n+m} - S_n\}).
\]

Thus, according to Lemma 4.2,

\[
(4.1) \quad C^{(1)}_n + C^{(2)}_m - 2G(R^{(1)}_n, R^{(2)}_m) \leq C_{n+m} \leq C^{(1)}_n + C^{(2)}_m,
\]

where \( C^{(1)}_n \) and \( C^{(2)}_m \) \((R^{(1)}_n \text{ and } R^{(2)}_m)\) are independent and have the same law as \( C_n \) and \( C_m \) \((R_n \text{ and } R_m)\), respectively. Further, for \( k \geq 1 \) define \( \overline{C}_k = C_k - E[C_k] \), and similarly \( \overline{C}^{(1)}_k \) and \( \overline{C}^{(2)}_k \). By taking expectation in (4.1) and then subtracting those two relations yields

\[
\left| \overline{C}_{n+m} - (\overline{C}^{(1)}_n + \overline{C}^{(2)}_m) \right| \leq 2 \max \{G(R^{(1)}_n, R^{(2)}_m), E[G(R^{(1)}_n, R^{(2)}_m)]\}.
\]

Denote \( \|\cdot\|_2 = E(\cdot)^2 \). Clearly, \( \text{Var}(C_k) = \|\overline{C}_k\|_2^2 \), \( k \geq 1 \). Now, independence together with \( E[G(R^{(1)}_n, R^{(2)}_m)] \leq \|G(R^{(1)}_n, R^{(2)}_m)\|_2 \) and Lemma 3.2 implies

\[
\|\overline{C}_{n+m}\|_2 \leq (\|\overline{C}^{(1)}_n\|_2^2 + \|\overline{C}^{(2)}_m\|_2^2)^{1/2} + 4\|G(R^{(1)}_n, R^{(2)}_m)\|_2 \leq (\|\overline{C}^{(1)}_n\|_2^2 + \|\overline{C}^{(2)}_m\|_2^2)^{1/2} + c_1 h_d(n + m),
\]

where in the last inequality we used

\[
G(R^{(1)}_n, R^{(2)}_m) \leq G(R^{(1)}_{n+m}, R^{(2)}_{n+m}).
\]

Consequently,

\[
\|\overline{C}_{n+m}\|_2^2 \leq \|\overline{C}_n\|_2^2 + \|\overline{C}_m\|_2^2 + c_2 (\|\overline{C}_n\|_2^2 + \|\overline{C}_m\|_2^2)^{1/2} h_d(n + m) + c_3 h_d^2(n + m).
\]

By setting \( a_k = \|\overline{C}_k\|_2^2 \), \( k \geq 1 \), the above relation reads

\[
a_{n+m} \leq a_n + a_m + c_2 (\|\overline{C}_n\|_2^2 + \|\overline{C}_m\|_2^2)^{1/2} h_d(n + m) + c_3 h_d^2(n + m).
\]

In the sequel we prove that

\[
c_2 (\|\overline{C}_n\|_2^2 + \|\overline{C}_m\|_2^2)^{1/2} h_d(n + m) + c_3 h_d^2(n + m) \leq c \sqrt{n + m} h_d^2(n + m).
\]

Thus, by defining \( b_k = c \sqrt{k} h_d^2(k) \), \( k \geq 1 \), and recalling that \( d \geq 3 \alpha \) the assertion of the lemma follows directly from Lemma 4.1.

Clearly, it suffices to show that

\[
\|\overline{C}_n\|_2 \leq c \sqrt{n} h_d(n), \quad n \geq 1.
\]

For \( k \geq 1 \) we set

\[
a_k = \sup \left\{ \|\overline{C}_i\|_2 : 2^k \leq i \leq 2^{k+1} \right\}.
\]

Further, for \( k \geq 2 \) we take \( n \geq 1 \) such that \( 2^k \leq n < 2^{k+1} \), and we set \( l = \lfloor n/2 \rfloor \) and \( m = n - l \). Here \( \lfloor a \rfloor \) stands for the largest integer smaller than or equal to \( a \in \mathbb{R} \).

Analogously as above we have

\[
C^{(1)}_l + C^{(2)}_m - 2G(R^{(1)}_l, R^{(2)}_m) \leq C_n \leq C^{(1)}_l + C^{(2)}_m,
\]

from which we again conclude

\[
\|\overline{C}_n\|_2 \leq (\|\overline{C}^{(1)}_l\|_2^2 + \|\overline{C}^{(2)}_m\|_2^2)^{1/2} + c_4 h_d(n).
\]
Recall that $C_i^{(1)}$ and $C_m^{(2)} (\mathcal{R}_i^{(1)}$ and $\mathcal{R}_m^{(2)})$ are independent and have the same law as $C_i$ and $C_m (\mathcal{R}_i$ and $\mathcal{R}_m)$, respectively. Hence

$$\|\bar{C}_n\|_2 \leq 2^{1/2} \alpha_{k-1} + c_4 h_d(n).$$

Taking supremum over $2^k \leq n \leq 2^{k+1}$ yields

$$\alpha_k \leq 2^{1/2} \alpha_{k-1} + c_4 h_d(2^{k+1}).$$

We next set $\beta_k = \alpha_k / h_d(2^k)$. In view of [6, Theorem 1.5.6] we get that $h_d(2^{k+1}) \leq c h_d(2^k)$. Thus

$$\beta_k \leq 2^{1/2} \beta_{k-1} + c_5.$$

By iteration of this inequality we have $\beta_k \leq c_6 2^{k/2}$ which implies $\alpha_k \leq c_6 2^{k/2} h_d(2^k)$. Finally, using definition of $\alpha_k$ and [6, Theorem 1.5.6] we get

$$\|\bar{C}_n\|_2^2 \leq \alpha_k^2 \leq c_6 2^{k/2} h_d^2(2^k) \leq c_7 n h_d^2(n),$$

which concludes the proof. $\square$

5. CLT for $\{C_n\}_{n \geq 0}$

In this section, we first show strict positivity of the limit $\sigma_d$ from Lemma 4.3, and then we finally prove Theorem 1.1. Namely, $\sigma_d$ will be exactly the variance parameter of the limiting normal law in (1.1). To show that $\sigma_d$ is strictly positive we adapt an idea from [2] where the simple random walk is decomposed into two independent processes. The first is the process counting the number of double-backtracks, and the second is the process with no double-backtracks. For our class of random walks we use one-step loops instead of double-backtracks. To be more precise, we say that $\{S_n\}_{n \geq 0}$ makes a one-step loop at time $n$ if $S_n = S_{n-1}$. Clearly, $\{S_n\}_{n \geq 0}$ admits one-step loops if and only if $p_1(0) > 0$. Also, when the walk makes a one-step loop, the range evidently remains unchanged. We will first build a random walk $\{\tilde{S}_n\}_{n \geq 0}$ with no one-step loops, and then we will show how to construct a random walk $\{\hat{S}_n\}_{n \geq 0}$ starting from $\{\tilde{S}_n\}_{n \geq 0}$ with (i) the same law as $\{S_n\}_{n \geq 0}$, and (ii) the range process being a certain random time-change of the range process of $\{\tilde{S}_n\}_{n \geq 0}$.

Finally, to prove Theorem 1.1 we combine Lindeberg-Feller central limit theorem (see [8, Theorem 3.4.5] or Lemma 5.6) and a dyadic version of the capacity decomposition formula from Lemma 4.2 (see [2, Corollary 2.1] or Lemma 5.5).

**Strict positivity of $\sigma_d$.** Assume (A1)-(A4), and let $\{\widetilde{X}_i\}_{i \in \mathbb{N}}$ be a sequence of i.i.d. random variables with distribution

$$\mathbb{P}(\widetilde{X}_i = x) = \frac{p_1(x)}{1-p} 1_{\{x \neq 0\}}.$$

Recall that $p = p_1(0) > 0$ (assumption (A4)). Further, let $\{\tilde{S}_n\}_{n \geq 0}$ be the corresponding random walk. Clearly, $\{\tilde{S}_n\}_{n \geq 0}$ has no one-step loops. We now construct a random walk $\{\hat{S}_n\}_{n \geq 0}$ by adding an independent geometric number of one-step loops to $\{\tilde{S}_n\}_{n \geq 0}$ at each step, and which has the same law as $\{S_n\}_{n \geq 0}$. Let $\{\xi_i\}_{i \geq 0}$ be a sequence of i.i.d. geometric random variables with parameter $p$ which are independent of $\{\tilde{S}_n\}_{n \geq 0}$. Recall,

$$\mathbb{P}(\xi_i = k) = p^k(1 - p), \quad k \geq 0.$$
Lemma 5.1. Assume \( \{\xi_i\}_{i \geq 0} \) which means that we set \( \{\xi_i\}_{i \geq 0} \) and define \( \{\tilde{S}_n\}_{n \geq 0} \) according to the following procedure: We start by setting \( \tilde{S}_0 = 0 \). Further, for \( k \geq 0 \) we define

\[
I_k = [k + N_{k-1} + 1, k + N_k],
\]

If \( I_k \neq \emptyset \) then for each \( i \in I_k \) we define \( \tilde{S}_i = \tilde{S}_k \). We next follow the path of \( \{\tilde{S}_n\}_{n \geq 0} \) which means that we set \( \tilde{S}_{k+N_{k+1}} = \tilde{S}_{k+1} \). This construction provides a random walk \( \{\tilde{S}_n\}_{n \geq 0} \) with the same law as \( \{S_n\}_{n \geq 0} \). We also have

\[
\tilde{S}_n = \tilde{S}_{n+N_n} = \tilde{S}_{n+N_{n-1}}, \quad n \geq 0,
\]

where the second equality holds since \( n + N_{n-1} = (n - 1) + N_{n-1} + 1 \). Consequently,

\[
\tilde{R}_n = \tilde{R}_{n+N_n} = \tilde{R}_{n+N_{n-1}}, \quad n \geq 0,
\]

where \( \{\tilde{R}_n\}_{n \geq 0} \) and \( \{\tilde{R}_n\}_{n \geq 0} \) are range processes of \( \{\tilde{S}_n\}_{n \geq 0} \) and \( \{\tilde{S}_n\}_{n \geq 0} \), respectively.

We now show that \( \sigma_d \) must be strictly positive. We first establish two technical lemmas.

**Lemma 5.1.** Assume \((A1)-(A4)\) and \( d \geq 3a \). Then for any \( c, c' > 0 \) it holds that

\[
\lim_{n \to \infty} \mathbb{P}(G(\tilde{R}_n, \tilde{R}[n, [n + c'n]]) \geq c\sqrt{n}) = 0,
\]

where \( G(x, y) \) is the Green function of \( \{S_n\}_{n \geq 0} \) (or \( \{\tilde{S}_n\}_{n \geq 0} \)).

**Proof.** Let \( M_n \) be the number of one-step loops added in the time interval \([n, n + c'n]\), that is,

\[
M_n = \xi_n + \ldots + \xi_{[n + c'n]}.
\]

Since \( \tilde{S}_{[n+c'n]} = \tilde{S}_{[n+c'n]+N_{[n+c'n]}} \) and

\[
N_{[n+c'n]} = \sum_{i=0}^{[n+c'n]} \xi_i = \sum_{i=0}^{n-1} \xi_i + \sum_{i=n}^{n+c'n} \xi_i = N_{n-1} + M_n,
\]

we have \( \tilde{S}_{[n+c'n]} = \tilde{S}_{[n+c'n]+N_{[n+c'n]+M_n}} \). This together with \( \tilde{S}_n = \tilde{S}_{n+N_{n-1}}, n \geq 0 \), implies

\[
\tilde{R}[n, [n + c'n]] = \tilde{R}[n + N_{n-1}, [n + c'n] + N_{n-1} + M_n].
\]

Therefore

\[
\mathbb{P}(G(\tilde{R}_n, \tilde{R}[n, [n + c'n]]) \geq c\sqrt{n}) \leq \mathbb{P}(G(\tilde{R}_{n+N_{n-1}}, \tilde{R}[n + N_{n-1}, [(1 + c' + c_1)n] + N_{n-1}]) \geq c\sqrt{n}) + \mathbb{P}(M_n \geq c_1n),
\]

where \( c_1 > 0 \) is a constant that we specify. For that, notice that there exists a constant \( c_2 > 0 \) such that \( \mathbb{E}[M_n] \leq c_2n, n \geq 0 \). Set \( c_1 = c_2 + \epsilon \) for some \( \epsilon > 0 \). Then, by Chebyshev’s inequality we have

\[
\mathbb{P}(M_n \geq c_1n) = \mathbb{P}(M_n - c_2n \geq \epsilon n) \leq \frac{\text{Var}(M_n)}{\epsilon^2 n^2} \to 0.
\]
To bound the first term of the penultimate estimate we observe that $G(x - a, y - a) = G(x, y)$, $x, y, a \in \mathbb{Z}^d$, and that the two random variables

$$\tilde{R}_{n+N_{n-1}} - \tilde{S}_{n+N_{n-1}} \quad \text{and} \quad \tilde{R}_n + N_{n-1}, [(1 + c' + c_1)n] + N_{n-1} - \tilde{S}_{n+N_{n-1}}$$

are independent. Thus, instead of the second random set we can write $\mathcal{R}'_{[(c' + c_1)n]}$, where $\{\mathcal{R}'_n\}_{n \geq 0}$ is the range process of a random walk that is an independent copy of $\{\tilde{S}_n\}_{n \geq 0}$. We obtain

$$\mathbb{P}(G(\tilde{R}_{n+N_{n-1}} - \tilde{S}_{n+N_{n-1}}, \mathcal{R}'_{[(c' + c_1)n]}) \geq c\sqrt{n})$$

and

$$\mathbb{P}(G(\tilde{R}_{[(1 + c_1)n]}, \mathcal{R}'_{[(c' + c_1)n]}) \geq c\sqrt{n}) + \mathbb{P}(N_{n-1} \geq c_3 n),$$

where the constant $c_3$ is defined as above to make $\mathbb{P}(N_{n-1} \geq c_3 n)$ tending to zero as $n$ goes to infinity. We finally set $c_4 = \max\{1 + c_3, |c' + c_1|\}$ and we apply the Markov inequality, Lemma 3.2 and [6, Theorem 1.5.6] to get

$$\mathbb{P}(G(\tilde{R}_{[(1 + c_1)n]}, \mathcal{R}'_{[(c' + c_1)n]}) \geq c\sqrt{n}) \leq (c\sqrt{n})^{-1} \mathbb{E}[G(\tilde{R}_{c_4 n}, \mathcal{R}'_{c_4 n})] \leq c_3 n^{-1/2} h_d(n).$$

The last term tends to zero as $d \geq 3\alpha$ and this implies the result.

In what follows, we use the notation $\tilde{C}[m, n] = \text{Cap}(\tilde{R}[m, n]), \tilde{C}[m, n] = \text{Cap}(\tilde{R}[m, n]), \tilde{C}_n = \text{Cap}(\tilde{R}_n)$ and $\tilde{C}_n = \text{Cap}(\tilde{R}_n), m, n \geq 0.$

**Lemma 5.2.** Assume (A4) and that $\{S_n\}_{n \geq 0}$ (or $\{\tilde{S}_n\}_{n \geq 0}$) is transient. Then for any $k \geq 0$

$$\lim_{n \to \infty} \frac{\tilde{C}[k, k + n]}{n} = \frac{\mu_d}{1 - p} \quad \text{P-a.s.,}$$

where $\mu_d$ is the limit from (2.1).

**Proof.** Since $\tilde{S}_k = \tilde{S}_{k+N_{k-1}}$ and $\tilde{S}_k + n = \tilde{S}_{k+n+N_{k-1}}$, we have

$$\tilde{R}[k, k + n] = \tilde{R}[k + N_{k-1}, k + n + N_{k+n}], \quad n, k \geq 0.$$ 

Observe that $N_{k+n} = N_{k-1} + N[k, k + n]$, where $N[k, k + n] = \sum_{i=k}^{k+n} \xi_i$. Hence

$$\tilde{C}[k, k + n] = \tilde{C}[k + N_{k-1}, k + n + N_{k-1} + N[k, k + n]].$$

By the strong law of large numbers

$$\lim_{n \to \infty} \frac{N[k, k + n]}{n} = \frac{p}{1 - p} \quad \text{P-a.s.}$$

Therefore

$$\lim_{n \to \infty} \frac{\tilde{C}[k, k + n]}{n} = \frac{\mu_d}{1 - p} \quad \text{P-a.s.}$$

as desired.

We finally prove strict positiveness of $\sigma_d$.

**Lemma 5.3.** Assume (A1)-(A4) and $d \geq 3\alpha$. Then $\sigma_d > 0$.

**Proof.** We define three sequences

$$i_n = [(1 - p)(n - A\sqrt{n})], \quad j_n = [(1 - p)n], \quad k_n = [(1 - p)(n + A\sqrt{n})], \quad n \geq 1,$$
for a constant $A > 0$ which will be specified later. Lemma 5.2 implies

$$\lim_{n \to \infty} \frac{\widetilde{C}[j_n, k_n]}{\sqrt{n}} = A \mu_d \quad \mathbb{P} \text{-a.s.}$$

Thus, for $n$ large enough

$$(5.1) \quad \mathbb{P}(\widetilde{C}[j_n, k_n] \geq 3A \mu_d \sqrt{n/4}) \geq \frac{3}{4}.$$

Similarly, we show that for $n$ large enough

$$(5.2) \quad \mathbb{P}(\widetilde{C}[i_n, j_n] \geq 3A \mu_d \sqrt{n/4}) \geq \frac{3}{4}.$$

By Lemma 5.1 we get for $n$ large enough

$$(5.3) \quad \mathbb{P}\left(G(\widetilde{R}[0, j_n], \widetilde{R}[j_n, k_n]) > A \mu_d \sqrt{n/8}\right) \leq \frac{1}{8}$$

and

$$(5.4) \quad \mathbb{P}\left(G(\widetilde{R}[0, i_n], \widetilde{R}[i_n, j_n]) > A \mu_d \sqrt{n/8}\right) \leq \frac{1}{8}.$$

We introduce the following events

$$B_n = \left\{ \frac{N_{i_n-1} - \mathbb{E}[N_{i_n-1}]}{\sqrt{n}} \in [A + 1, A + 2] \right\},$$

$$D_n = \left\{ \frac{N_{k_n-1} - \mathbb{E}[N_{k_n-1}]}{\sqrt{n}} \in [1 - A, 2 - A] \right\}.$$

By the central limit theorem, there exists a constant $c_A > 0$ such that $\mathbb{P}(B_n) \geq c_A$ and $\mathbb{P}(D_n) \geq c_A$ for $n$ large enough. We distinguish between two cases:

(i) $\mathbb{P}(\widetilde{C}[j_n] \geq \mathbb{E}[\widetilde{C}[j_n]]) \geq 1/2$;

(ii) $\mathbb{P}(\widetilde{C}[j_n] \leq \mathbb{E}[\widetilde{C}[j_n]]) \geq 1/2$.

We first study case (i). By Lemma 4.2 we have

$$\widetilde{C}[0, k_n] \geq \widetilde{C}[0, j_n] + \widetilde{C}[j_n, k_n] - 2G(\widetilde{R}[0, j_n], \widetilde{R}[j_n, k_n]).$$

We thus obtain

$$\mathbb{P}\left(\widetilde{C}[0, k_n] \geq \mathbb{E}[\widetilde{C}[k_n]] + A \mu_d \sqrt{n/2}\right) \geq \mathbb{P}\left(\widetilde{C}[0, j_n] \geq \mathbb{E}[\widetilde{C}[j_n]], \widetilde{C}[j_n, k_n] \geq 3A \mu_d \sqrt{n/4}\right) - \mathbb{P}\left(G(\widetilde{R}[0, j_n], \widetilde{R}[j_n, k_n]) > A \mu_d \sqrt{n/8}\right).$$

In view of the assumption, space homogeneity of the capacity and (5.1) we have that

$$\mathbb{P}\left(\widetilde{C}[0, j_n] \geq \mathbb{E}[\widetilde{C}[j_n]], \widetilde{C}[j_n, k_n] \geq 3A \mu_d \sqrt{n/4}\right)$$

$$= \mathbb{P}\left(\text{Cap}(\widetilde{R}[j_n] - \widetilde{S}[j_n]) \geq \mathbb{E}[\widetilde{C}[j_n]], \text{Cap}(\widetilde{R}[j_n, k_n] - \widetilde{S}[j_n]) \geq 3A \mu_d \sqrt{n/4}\right)$$

$$= \mathbb{P}\left(\text{Cap}(\widetilde{R}[j_n] - \widetilde{S}[j_n]) \geq \mathbb{E}[\widetilde{C}[j_n]]\right) \mathbb{P}\left(\text{Cap}(\widetilde{R}[j_n, k_n] - \widetilde{S}[j_n]) \geq 3A \mu_d \sqrt{n/4}\right)$$

$$= \mathbb{P}\left(\widetilde{C}[0, j_n] \geq \mathbb{E}[\widetilde{C}[j_n]]\right) \mathbb{P}\left(\widetilde{C}[j_n, k_n] \geq 3A \mu_d \sqrt{n/4}\right) \geq \frac{3}{8}.$$
This together with (5.3) implies
\[ P\left( \tilde{C}[0, k_n] \geq E[\hat{C}_n] + \frac{1}{2} A\mu_d \sqrt{n} \right) \geq \frac{1}{4}. \]

By independence of \( \{N_n\}_{n \geq 1} \) and \( \{\tilde{S}_n\}_{n \geq 0} \) we get
\[ P\left( \tilde{C}[0, k_n] \geq E[\hat{C}_n] + \frac{1}{2} A\mu_d \sqrt{n}, D_n \right) \geq \frac{c_A}{4}. \]

We next observe that on \( D_n \) we have \( k_n + N_{k_{n-1}} \in [n, n + 2\sqrt{n}] \). We also recall that
\[ \tilde{R}[0, k_n] = \hat{R}[0, k_n + N_{k_{n-1}}], \]
and whence
\[ P\left( \exists m \leq 2\sqrt{n} : \hat{C}[0, n + m] \geq E[\hat{C}_n] + \frac{1}{2} A\mu_d \sqrt{n} \right) \geq \frac{c_A}{4}. \]

Since \( \{\hat{C}_n\}_{n \geq 0} \) is clearly increasing in \( n \), we deduce that
\[ P\left( \hat{C}[0, n + 2\sqrt{n}] \geq E[\hat{C}_n] + \frac{1}{2} A\mu_d \sqrt{n} \right) \geq \frac{c_A}{4}. \]

and, finally, the deterministic bound \( \hat{C}_{n+2\sqrt{n}} \leq \hat{C}_n + 2\sqrt{n} \) yields
\[ P\left( \hat{C}_n \geq E[\hat{C}_n] + (A\mu_d/2 - 2)\sqrt{n} \right) \geq \frac{c_A}{4}. \]

Choosing \( A \) large enough such that \( A\mu_d/2 - 2 > 0 \) and applying the Chebyshev’s inequality shows that in case (i) we have
\[ \text{Var}(C_n) = \text{Var}(\hat{C}_n) \geq cn, \]
as desired.

In case (ii) we proceed similarly. By Lemma 4.2, we have
\[ \tilde{C}[0, i_n] \leq \tilde{C}[0, j_n] - \tilde{C}[i_n, j_n] + 2G(\tilde{R}[0, i_n], \tilde{R}[i_n, j_n]). \]
Next, equations (5.2), (5.4) and the fact that \( P(B_n) \geq c_A \) imply
\[ P\left( \tilde{C}[0, i_n] \leq E[\hat{C}_n] - \frac{1}{2} A\mu_d \sqrt{n}, B_n \right) \geq \frac{c_A}{4}. \]

On \( B_n \) we have \( i_n + N_{i_{n-1}} \in [n, n + 2\sqrt{n}] \) and it follows that
\[ P\left( \exists m \leq 2\sqrt{n} : \hat{C}[0, n + m] \leq E[\hat{C}_n] - \frac{1}{2} A\mu_d \sqrt{n} \right) \geq \frac{c_A}{4}. \]

We thus finally conclude that
\[ P\left( \hat{C}_n \leq E[\hat{C}_n] - \frac{1}{2} A\mu_d \sqrt{n} \right) \geq \frac{c_A}{4} \]
and an application of the Chebyshev’s inequality finishes the proof. □
Proof of Theorem 1.1. We start with the following technical lemma.

Lemma 5.4. Assume (A1)-(A3) and $d \geq 3\alpha$. Then there is a constant $C > 0$ such that

$$\mathbb{E}[\overline{C}_n^2] \leq Cn^2, \quad n \geq 1,$$

where $\overline{C}_n = C_n - \mathbb{E}[C_n]$.

Proof. The proof is similar to that of Lemma 4.3. For $k \geq 1$ we set

$$\alpha_k = \sup \left\{ \|\overline{C}_n\|_4 : 2^k \leq n \leq 2^{k+1} \right\},$$

where $\|\cdot\|_4 = \mathbb{E}[(\cdot)^4]^{1/4}$. For $k \geq 2$ we take $2^k \leq n < 2^{k+1}$ and we set $l = \lfloor n/2 \rfloor$ and $m = n - l$. Using Lemma 4.2, as in the proof of Lemma 4.3, we obtain

$$\|\overline{C}_n\|_4 \leq \|\overline{C}_l^{(1)} + \overline{C}_m^{(2)}\|_4 + 4\|G(R_l^{(1)}, R_m^{(2)})\|_4,$$

where again $C_l^{(1)}$ and $C_m^{(2)}$ ($R_l^{(1)}$ and $R_m^{(2)}$) are independent and have the same law as $C_l$ and $C_m$ ($R_l$ and $R_m$), respectively. We observe that

$$\mathbb{E}\left[(\overline{C}_l^{(1)} + \overline{C}_m^{(2)})^4\right] = \mathbb{E}\left[(\overline{C}_l^{(1)})^4\right] + \mathbb{E}\left[(\overline{C}_m^{(2)})^4\right] + 6\epsilon_1\mathbb{E}\left[(\overline{C}_l^{(1)})^2\right] \mathbb{E}\left[(\overline{C}_m^{(2)})^2\right],$$

where we used the fact that $\overline{C}_l^{(1)}$ and $\overline{C}_m^{(2)}$ are two independent and centered random variables. From Lemma 4.3 we have

$$\mathbb{E}\left[(\overline{C}_l^{(1)})^2\right] \mathbb{E}\left[(\overline{C}_m^{(2)})^2\right] \leq c_1 n^2,$$

whereas, by Lemma 3.2,

$$\|G(R_l^{(1)}, R_m^{(2)})\|_4 \leq \|G(R_l^{(1)}, R_m^{(2)})\|_4 \leq c_2 h_2(n).$$

Combining this with the elementary inequality $(a + b)^{1/4} \leq a^{1/4} + b^{1/4}$, $a, b \geq 0$, we get

$$\|\overline{C}_n\|_4 \leq \left(\mathbb{E}\left[(\overline{C}_l^{(1)})^4\right] + \mathbb{E}\left[(\overline{C}_m^{(2)})^4\right]\right)^{1/4} + c_3 \sqrt{n}. $$

Similarly as in Lemma 4.3 we thus obtained

$$\alpha_k \leq 2^{1/4}\alpha_{k-1} + c_3 2^{k/2}.$$ 

Setting $\beta_k = 2^{-k/2}\alpha_k$, $k \geq 1$, we deduce that

$$\beta_k \leq \frac{1}{2^{1/4}}\beta_{k-1} + c_3,$$

which shows that $\{\beta_k\}_{k \geq 1}$ is a bounded sequence. Therefore, $\alpha_k \leq c_4 2^{k/2}$, $k \geq 1$, which immediately yields the result. \(\square\)

The proof of Theorem 1.1 is based on the dyadic capacity decomposition formula derived in [2, Corollary 2.1] and Lindeberg-Feller central limit theorem, which we state for reader’s convenience.

Lemma 5.5 ([2, Corollary 2.1]). Let $L, n \geq 1$ be such that $2^L \leq n$. Then,

$$\sum_{i=1}^{2^L} \text{Cap}(R_{n/2^L}^{(i)}) - 2 \sum_{i=1}^L \sum_{j=1}^{2^{i-1}} \epsilon_{j}^{(i)} \leq C_n \leq \sum_{i=1}^{2^L} \text{Cap}(R_{n/2^L}^{(i)}).$$
where \( \{ R^{(i)}_{n/2^l} \}_{i=1}^{L} \) are independent and \( R^{(i)}_{n/2^l} \) has the same law as \( R_{[n/2^l]} \) or \( R_{[n/2^l+1]} \), and for each \( l = 1, \ldots, L \) the random variables \( \{ E^{(i)}_l \}_{i=1}^{2^{l-1}} \) are independent and \( E^{(i)}_l \) has the same law as \( G(R^{(i)}_{n/2^l}, R^{(i)}_{n/2^l}) \) with \( \{ R^{(i)}_n \}_{n \geq 0} \) being an independent copy of \( \{ R_n \}_{n \geq 0} \).

Lemma 5.6 ([18, Theorem 4.5]). For each \( n \geq 1 \) let \( \{ X_{n,m} \}_{1 \leq m \leq n} \) be a sequence of independent random variables. If

(i) \( \sum_{m=1}^{n} \text{Var}(X_{n,m}) \xrightarrow{n \to \infty} \sigma > 0; \)

(ii) for every \( \varepsilon > 0 \), \( \sum_{m=1}^{n} \mathbb{E} \left[ (X_{n,m} - \mathbb{E}[X_{n,m}])^2 \mathbb{1}_{|X_{n,m} - \mathbb{E}[X_{n,m}]| > \varepsilon} \right] \xrightarrow{n \to \infty} 0, \)

then \( X_{n,1} + \cdots + X_{n,n} \xrightarrow{(d)} \sigma N(0, 1). \)

Finally, we prove Theorem 1.1.

Proof of Theorem 1.1. Denote \( C^{(i)}_{n/2^L} = \text{Cap}(R^{(i)}_{n/2^L}) \), \( i = 1, \ldots, L \). By taking expectation in (5.6) and then subtracting those two relations we obtain

\[
\sum_{i=1}^{2^L} C^{(i)}_{n/2^L} - 2 \sum_{l=1}^{L} \sum_{i=1}^{2^{l-1}} E^{(i)}_l \leq C_n \leq \sum_{i=1}^{2^L} \overline{C}^{(i)}_{n/2^L} + 2 \sum_{l=1}^{L} \sum_{i=1}^{2^{l-1}} \mathbb{E}[E^{(i)}_l].
\]

Further, define

\[
E(n) = \sum_{i=1}^{2^L} C^{(i)}_{n/2^L} - C_n,
\]

using (5.7) and Lemma 3.2, we get that

\[
\mathbb{E}[|E(n)|] \leq 4 \mathbb{E} \left[ \sum_{l=1}^{L} \sum_{i=1}^{2^{l-1}} E^{(i)}_l \right] \leq c_1 \sum_{l=1}^{L} \sum_{i=1}^{2^{l-1}} \mathbb{E}[E^{(i)}_l] \leq c_2 h_d(n) \sum_{l=1}^{L} 2^{l-1} \leq c_2 2^L h_d(n).
\]

We choose \( L = \lfloor \log_2(n^{1/4}) \rfloor \) which implies

\[
\lim_{n \to \infty} \frac{\mathbb{E}[|E(n)|]}{\sqrt{n}} = 0.
\]

We are thus left to prove that

\[
\sum_{i=1}^{2^L} \overline{C}^{(i)}_{n/2^L} \xrightarrow{(d)} \sigma_d N(0, 1),
\]

where \( \sigma_d > 0 \) is from Lemma 4.3. To establish this result we apply the Lindeberg-Feller central limit theorem. By Lemma 4.3 we have

\[
\lim_{n \to \infty} \sum_{i=1}^{2^L} \frac{\text{Var}(\overline{C}^{(i)}_{n/2^L})}{n} = \sigma_d,
\]

which means that the first Lindeberg-Feller condition is satisfied. It remains to check that for any \( \varepsilon > 0 \) it holds that

\[
\lim_{n \to \infty} \sum_{i=1}^{2^L} \frac{1}{n} \mathbb{E} \left[ \left( \overline{C}^{(i)}_{n/2^L} \right)^2 \mathbb{1}_{|\overline{C}^{(i)}_{n/2^L}| > \varepsilon \sqrt{n}} \right] = 0.
\]
Observe that by the Cauchy-Schwartz inequality we have
\[
\mathbb{E}\left[\left(\overline{C}_{n/2^L}^{(i)}\right)^2 \mathbb{1}_{\{\overline{C}_{n/2^L}^{(i)} > \epsilon \sqrt{n}\}}\right] \leq \left(\mathbb{E}\left[\left(\overline{C}_{n/2^L}^{(i)}\right)^4\right]\right)^{1/2} \mathbb{P}(\overline{C}_{n/2^L}^{(i)} > \epsilon \sqrt{n})^{1/2}.
\]
Further, the Chebyshev inequality combined with Lemma 4.3, strict positivity of \( \sigma_d \) and Lemma 5.4, imply
\[
\mathbb{E}\left[\left(\overline{C}_{n/2^L}^{(i)}\right)^4\right] \mathbb{P}(\overline{C}_{n/2^L}^{(i)} > \epsilon \sqrt{n}) \leq c_3 \left(\frac{n}{2^L}\right)^2 \frac{\text{Var}(\overline{C}_{n/2^L}^{(i)})}{\epsilon^2 n} \leq c_4 \frac{n^2}{\epsilon^2 2^L}.
\]
Based on the choice \( L = \lfloor \log_2(n^{1/4}) \rfloor \), we conclude that
\[
\sum_{i=1}^{2^L} \frac{1}{n} \mathbb{E}\left[\left(\overline{C}_{n/2^L}^{(i)}\right)^2 \mathbb{1}_{\{\overline{C}_{n/2^L}^{(i)} > \epsilon \sqrt{n}\}}\right] \leq \frac{c_5}{\epsilon^2 2^{L/2}} \frac{n^{1/2}}{e^{1/2} 2^{3L}} \rightarrow 0,
\]
and this finishes the proof. \( \square \)

ACKNOWLEDGEMENT

We wish to thank R. L. Schilling for stimulating discussions. This work has been supported by Deutscher Akademischer Austauschdienst (DAAD) and Ministry of Science and Education of the Republic of Croatia (MSE) via project Random Time-Change and Jump Processes. Financial support through the Croatian Science Foundation under projects 8958 and 4197 (for N. Sandrić and S. Šebek) is gratefully acknowledged.
