The large conductance, Ca2+-activated K+ channels (BKCa, KCa1.1) are expressed in various brain neurons where they play important roles in regulating action potential duration, firing frequency and neurotransmitter release. Membrane potential depolarization and rising levels of intracellular Ca2+ gated BKCa channels, which in turn results in an outward K+ flux that re/hyperpolarizes the membrane. The sensitivity of BKCa channels to Ca2+ provides an important negative-feedback system for Ca2+ entry into brain neurons and suppresses repetitive firing. Thus, BKCa channel loss-of-function gives rise to neuronal hyperexcitability, which can lead to seizures. Evidence also indicates that BKCa channels can facilitate high-frequency firing (gain-of-function) in some brain neurons. Interestingly, both gain-of-function and loss-of-function mutations of genes encoding for various BKCa channel subunits have been associated with the development of neuronal excitability disorders, such as seizure disorders. The role of BKCa channels in the etiology of some neurological diseases raises the possibility that these channels can be used as molecular targets to prevent and suppress disease phenotypes.

BKCa CHANNELS AND NEURONAL EXCITABILITY

Intrinsic membrane properties play an important role in the control of neuronal activity in the central nervous system (CNS). Alterations of intrinsic membrane properties can contribute to diseases of neuronal excitability such as epilepsy. Potassium (K+) channels in particular are well known for their role in the regulation of membrane excitability due to their ability to stabilize the membrane potential. Compelling evidence indicates that K+ channels are critical molecular determinants for seizure generation and epileptogenesis. One particular type of K+ channel, the large conductance, Ca2+-activated K+ channel (BKCa, KCa1.1) is considered to be one of the intrinsic molecular determinants for the control of neuronal excitability in the CNS. Unlike other K+ channels, BKCa channels are activated by both voltage and elevated levels of intracellular Ca2+, resulting in large K+ conductances which in turn re/hyperpolarizes the membrane. The sensitivity of BKCa channels to Ca2+ provides an important negative feedback for Ca2+ entry into brain neurons; thus, BKCa channels may serve as a link between membrane depolarization and Ca2+ signaling to provide a rapid response to reduce or prevent neuronal hyperexcitability.

BKCa channels are tetramers of four α subunits, which form the ion channel pore, and four regulatory β (β1–4) subunits that are expressed in various tissues, including the brain (Pallanek and Genetzký, 1994; Jiang et al., 1999). BKCa channels can also be regulated by acidification (Brelidze and Magleby, 2004; Hou et al., 2008), ethanol (Liu et al., 2008), protein kinase phosphorylation (Tian et al., 2001; Zhou et al., 2010), ubiquitination (Liu et al., 2014) and palmitoylation (Shipston, 2013; Zhou et al., 2012). Of particular importance, protein S-palmitoylation (or palmitoylation) and ubiquitination control the cell surface expression and activity of BKCa, thereby critically contributing to BKCa channel functions (Shipston, 2013; Liu et al., 2014). Notably, the palmitoylation of BKCa channel β subunits promotes the exit of the pore-forming α subunit from the endoplasmic reticulum and promotes BKCa channel surface expression (Chen et al., 2013). The BKCa channel α subunit is encoded by the Slo1 gene, which can be subjected to splicing to produce channels with different functional properties and sensitivity to Ca2+; including the STREX (stress-axis hormone-regulated exon) channels (Xie and McCobb, 1998; Chen et al., 2005). Expression profiling studies have reported that BKCa channel α subunits are broadly expressed in the CNS (Chang et al., 1997; Wanner et al., 1999; Sausbier et al., 2006). The regulatory BKCa channel β1 and β4 subunits are also expressed in the brain, whereas the β2 and β3 subunits are nearly absent in the brain (Tseng-Crank et al., 1996). BKCa channels are predominantly located at the axon and presynaptic terminals, associated with glutamatergic synapses in hippocampus and cortex and GABAergic synapses in the cerebellum (Knaus et al., 1996; Hu et al., 2001; Misonou et al., 2006; Martire et al., 2010). These channels are usually found in close proximity to N-methyl-D-aspartate receptors (Iasacson and Murphy, 2001) and voltage-gated Ca2+ channels (Cav), including Cav1.2, Cav2.2, and Cav2.1 in the CNS (Marrion and Tavalin, 1998; Grunnet and Kaufmann, 2004). During an action potential (AP), both membrane depolarization and elevated intracellular Ca2+ can activate BKCa channels, which in turn contribute to AP fast repolarization, generate the fast component of the afterhyperpolarization (AHP) and reduce Ca2+ influx via inactivation of Cav channels. Prominently, AP repolarization and fAHP significantly contribute to AP shape and duration. By controlling the AP shape and duration, BKCa channels can regulate neuronal excitability and some Ca2+ transients that underlie the release of neurotransmitter at presynaptic terminals.
The mechanisms underlying the inhibitory and excitatory role of BK$_{Ca}$ channels are complex (Figure 1). Functional studies have reported that the activation of BK$_{Ca}$ channels is hyperpolarizing; thus the resulting net effect on membrane excitability is inhibitory. However, evidence suggests that the activation of BK$_{Ca}$ channels can also facilitate high-frequency firing in some brain neurons, including CA1 pyramidal cells of the hippocampus (Gu et al., 2007). In physiological conditions, BK$_{Ca}$ channels activate slowly during an AP, allowing intracellular $\text{Ca}^{2+}$ to activate $\text{Ca}^{2+}$-dependent conductances such as the small conductance $\text{Ca}^{2+}$-activated $\text{K}^{+}$ (SK$_{Ca}$) channels, thereby inhibiting repetitive firing. The inhibitory effect following the activation of BK$_{Ca}$ channels may result from a delay in the development of an AP spike or decrease in fAHP conductances. Altered extracellular $\text{K}^{+}$ levels can modify the cell membrane potential to persistently depolarized values that may lead to paroxysmal discharges (Lebovitz, 1996). Interestingly, conversion from regular firing into burst firing upon the elevation of extracellular $\text{K}^{+}$ has been observed in hippocampal slices (Jensen et al., 1994; Jensen and Yaari, 1997). Blockade of BK$_{Ca}$ channels also can inhibit neuronal firing because the resulting AP broadening can allow the activation of slow-onset voltage-gated $\text{K}^{+}$ channels, such as small SK$_{Ca}$ channels and delayed rectifier $\text{K}^{+}$ channels. The resulting $\text{K}^{+}$ currents associated with an increased inactivation of voltage-gated $\text{Na}^{+}$ ($\text{Na}_V$) channels could slow the depolarization during an interspike interval. Further, excitation following the activation of upregulated BK$_{Ca}$ channels may result from their role in the generation of fast spike repolarization and fAHP, which would favor a reduced activation of SK$_{Ca}$ channels and delayed rectifier $\text{K}^{+}$ channels and would indirectly facilitate the recovery of $\text{Na}_V$ from inactivation (Gu et al., 2007). The upregulation of BK$_{Ca}$ channels may cause large increase in extracellular $\text{K}^{+}$, which in turn reduces the driving force for inhibitory $\text{K}^{+}$ currents leading to enhanced neuronal excitability. The activation of BK$_{Ca}$ channels can reduce neurotransmitter (GABA) release by shortening the duration of depolarization to allow $\text{Ca}^{2+}$ entry via $\text{Ca}_V$ channels, resulting in enhanced neuronal excitability (Hu et al., 2001; Raffaelli et al., 2004). There is also a possibility that the inhibitory and excitatory action of BK$_{Ca}$ channels may be age dependent. Indeed, smaller BK$_{Ca}$ channel currents were recorded in pyramidal neurons of the prefrontal cortex in developing animals compared with adolescent and adult animals (Ksiazek et al., 2013). Multiple lines of evidence indicate that a lower availability and/or expression of BK$_{Ca}$ channels may contribute to the broadening of APs during repetitive firing (Shao et al., 1999; Faber and Sah, 2003). Therefore, the lower availability of BK$_{Ca}$ channels in young animals may facilitate neuronal activity during this developmental stage. Given the relevance of BK$_{Ca}$ channels in the control of neuronal excitability, these channels have been implicated in the pathophysiology of several neurological disorders associated with altered neuronal excitability, including seizure disorders.

**FIGURE 1** | Proposed mechanisms associated with BK$_{Ca}$ loss-of-function and gain-of-function channels. BK$_{Ca}$ channel loss-of-function occurs when there is low abundance of the channel at the membrane surface but no change in the BK$_{Ca}$ channel number in the endoplasmic reticulum (ER, note that ubiquitination prevent channels from trafficking to the cell surface). Potential mechanisms underlying neuronal hyperexcitability following BK$_{Ca}$ channels loss-of-function include reduced fAHP conductances. BK$_{Ca}$ channel gain-of-function is characterized by the release of ubiquitinated BK$_{Ca}$ channels from the ER and their insertion into the membrane surface (Liu et al., 2014). Thus, impairing ubiquitination may lead to overexpression of BK$_{Ca}$ channels relative to control conditions. Potential mechanisms underlying neuronal hyperexcitability following BK$_{Ca}$ channels gain-of-function include: rapid AP repolarization that would favor reduced activation of SK$_{Ca}$ and delayed rectifier $\text{K}^{+}$ channels as well as facilitated the rate of recovery of $\text{Na}_V$ channels from inactivation.
**BKCa CHANNEL LOSS-OF-FUNCTION HYPOTHESIS**

**BKCa CHANNEL LOSS-OF-FUNCTION AND ENHANCED NEURONAL EXCITABILITY IN SEIZURE DISORDERS**

Epilepsy consists of a group of chronic neurological disorders characterized by spontaneous and recurrent seizures. These seizures result from aberrant neuronal excitability associated with abnormal connections in the brain. Because the activation of BKCa channels limits the depolarization-induced bursting activity in neurons, it is assumed that a loss-of-function in BKCa channels will promote neuronal hyperexcitability, which can lead to seizures. Accordingly, reduced fAHP conductances were found in dentate gyrus granule cells obtained from patients suffering from temporal lobe epilepsy (Williamson et al., 1993). Similarly, idiopathic generalized epilepsy (mostly typical absence epilepsy) in humans has been associated with a single nucleotide deletion in exon 4 (delA750) of the KCNMB3 gene encoding for BKCa channel β3 subunit (Lorenz et al., 2007). When expressed in a heterologous system, this mutation (BKCa channel β3b-V4 subunit isoform) exhibited BKCa channel loss-of-function, characterized by fast inactivation kinetics (Hu et al., 2003). The mutated KCNMB3 gene also has been found in patients with dup(3q) syndrome with seizures (Riazi et al., 1999).

BKCa channel loss-of-function has also been implicated in the pathophysiology of animal models of seizures and epilepsy. A transient loss of fAHP conductances was found in subicular neurons following a kindling model of epileptogenesis (Behr et al., 2000). In the genetically epilepsy-prone rat (GEPR), an inherited model of generalized tonic-clonic epilepsy, reduced fAHP conductances were reported in CA3 neurons of the hippocampus (Verma-Ahuja et al., 1995). Similarly, in preliminary experiments, we found that the current density of BKCa channels is significantly reduced in inferior colliculus (IC) neurons, the site of seizure initiation in this model. However, no significant change was observed in the abundance of BKCa channel α subunit proteins in IC neurons of the GEPR (N’Gouemo et al., 2009). Similarly, the expression of BKCa channel α subunit was not altered in the dentate gyrus of the Krushinskii-Molodkina rat, a model of inherited epilepsy (Savina et al., 2014). Nevertheless, the protein expression of BKCa channel β4 subunits was elevated in the dentate gyrus of the Krushinskii-Moslodkina rat (Savina et al., 2014). The upregulation of β4 subunit is consistent with loss-of-function because this subunit inhibits BKCa channel activity (Brenner et al., 2005). In a model of alcohol withdrawal seizures, BKCa channel loss-of-function was reported and characterized by reduced current density, decreased channel conductance and lower protein abundance of BKCa channel α subunit in IC neurons (N’Gouemo and Morad, 2014). However, these changes outlasted the period of alcohol withdrawal seizure susceptibility, suggesting that BKCa channel loss-of-function in IC neurons was associated with the long-term effects of alcohol withdrawal hyperexcitability. Whether BKCa channels in IC neurons play an important role in the pathogenesis of alcohol withdrawal seizures remains to be determined. In a pilocarpine post-status epilepticus model, a downregulation of BKCa channel α subunit mRNA and protein was found in the cortex and hippocampus, consistent with a loss-of-function of BKCa channels associated with seizure generation (Pacheco Otalora et al., 2008; Ermolinsky et al., 2011). Further analysis revealed that the remaining BKCa channels in the dentate gurus were essentially made of the BKCa channel STREX splice variant instead of the ZERO variant (Ermolinsky et al., 2011). Interestingly, inserting the STREX splice variant shifts the conductance/voltage relation of BKCa channels to the left so that the channels are active at more physiological Ca2+ and voltage levels (Shipston, 2013). However, elevated intracellular Ca2+ is associated with seizure activity and epileptogenesis (Sanabria et al., 2001; Raza et al., 2004), suggesting an altered function of the remaining STREX BKCa channels in the pilocarpine model.

**BKCa CHANNEL LOSS-OF-FUNCTION AND ENHANCED NEURONAL EXCITABILITY IN AUTISM SPECTRUM DISORDERS**

Autism spectrum disorders (ASD) are a heterogeneous group of genetic neurodevelopmental disorders characterized by impairment of social communication and behavioral problems. Interestingly, studies have reported a co-occurrence of ASD and epilepsy (Deykin and MacMahon, 1979). The prevalence of epilepsy and associated electroencephalogram abnormalities in ASD significantly exceeded that of the normal population (Tuchman and Rapin, 1997). The higher incidence of epileptiform electroencephalogram abnormalities was also reported in children with ASD without epilepsy (Tuchman and Rapin, 1997). Thus, autism may be classified as a disorder of neuronal excitability, suggesting a potential role for ion channels in the etiology of ASD. ASD-linked ion channels of interest include BKCa channels. A mutation in the KCNAM1 gene, which encodes for the α subunit of BKCa channels, has been reported in some ASD patients with epilepsy (Laumonnier et al., 2006). The mutated KCNAM1 gene also causes haploinsufficiency in ASD patients, suggesting a potential role of BKCa channels in the pathogenesis of ASD (Laumonnier et al., 2006). When expressed in a heterologous system, this mutation exhibits reduced BKCa channel currents consistent with a loss-of-function (Laumonnier et al., 2006). Whether the downregulation of BKCa channels directly contributes to the pathogenesis of autism-epilepsy phenotype remains unknown.

**BKCa CHANNEL LOSS-OF-FUNCTION AND REDUCED NEURONAL EXCITABILITY IN SEIZURE DISORDERS**

Evidence shows that pharmacological blockade of BKCa channels can trigger seizures and status epilepticus, providing compelling evidence that BKCa channel loss-of-function can contribute to epileptogenesis (Young et al., 2003). However, mice lacking BKCa channel α (and β1) subunits do not exhibit spontaneous seizures, consistent with no change or reduced CNS excitability (Sausbier et al., 2004). Thus, the elevated seizure susceptibility observed in animal models cannot be explained solely by a downregulation of BKCa channel α subunits. Notably, evidence shows that BKCa channels can be subjected to ubiquitination by CRL4A/CRBN and are therefore retained in the endoplasmic reticulum and prevented from trafficking to the cell surface. Deregulation of this control mechanism results in enhanced activity of neuronal BKCa channels and epileptogenesis (Liu et al., 2014). Notably, the
cereblon (CRBN) co-localizes with BK<sub>Ca</sub> channels in brain neurons and regulate their surface expression (Jo et al., 2005). The CRBN gene is highly expressed in the hippocampus, consistent with its role in the pathogenesis of limbic seizures (Liu et al., 2014).

**BK<sub>Ca</sub> CHANNEL GAIN-OF-FUNCTION HYPOTHESIS**

**BK<sub>Ca</sub> CHANNEL GAIN-OF-FUNCTION AND ENHANCED NEURONAL EXCITABILITY IN SEIZURE DISORDERS**

Although BK<sub>Ca</sub> channels are thought to reduce neuronal firing, evidence indicates that the gain-of-function of these channels can contribute to bursting activity and epileptogenesis. Indeed, upregulation of the α subunit and downregulation of the β4 subunit of BK<sub>Ca</sub> channels were found in the dentate gyrus neurons of Krushinskii-Molodkin rats subjected to audiogenic kindling, which induced enhanced seizure severity (Savina et al., 2014). These findings are consistent with the BK<sub>Ca</sub> channel gain-of-function associated with enhanced seizure severity because the β4 subunit inhibits BK<sub>Ca</sub> channel activity. Notably, genetic deletion of the β4 subunit of BK<sub>Ca</sub> channels facilitates the development of pilocarpine-induced seizures that are associated with gain-of-function of BK<sub>Ca</sub> channels, as characterized by elevated cell-surface expression of BK<sub>Ca</sub> channels, enhanced Ca<sup>2+</sup> sensitivity to BK<sub>Ca</sub> channels, larger currents and high-frequency firing in the dentate gyrus of the hippocampus (Brenner et al., 2005; Shrutii et al., 2012).

BK<sub>Ca</sub> channel gain-of-function has also been found in human epilepsy. Accordingly, in a family of patients suffering from generalized epilepsy (mostly absence epilepsy) and paroxysmal dyskinesia, a missense mutation (D434G) in exon 10 of the KCNMA1 gene that encodes the BK<sub>Ca</sub> channel α subunit has been found (Du et al., 2005). When expressed in a heterologous system, this mutation gave rise to gain-of-function of BK<sub>Ca</sub> channel currents characterized by larger currents, elevated open channel probability and enhanced Ca<sup>2+</sup> sensitivity to BK<sub>Ca</sub> channels (Du et al., 2005; Wang et al., 2009; Yang et al., 2010). The D434G mutation gain-of-function was potentiated in the presence of β<sub>2</sub> and β<sub>4</sub> subunits of BK<sub>Ca</sub> channels (Diez-Sampedro et al., 2006; Lee and Cui, 2009). Notably, a polymorphism in the β4 subunit has been associated with human epilepsy (Cavalleri et al., 2007). These findings suggest that D434G mutation-induced changes in BK<sub>Ca</sub> channels contribute to neuronal hyperexcitability and lead to generalized seizures and paroxysmal dyskinesia.

**BK<sub>Ca</sub> CHANNEL GAIN-OF-FUNCTION AND REDUCED NEURONAL EXCITABILITY IN SEIZURE DISORDERS**

BK<sub>Ca</sub> channels are found in excitatory neurons located in several brain sites, including the hippocampus, where they may promote high-frequency firing (Gu et al., 2007). Blockade of BK<sub>Ca</sub> channels in these brain sites may reduce or suppress neuronal hyperexcitability. Consistent with this hypothesis, the blockade of BK<sub>Ca</sub> channels suppressed pentylenetetrazole-induced epileptiform activity as well as spontaneous bursting activity in cortical neurons obtained from EL mouse, an inherited model of epilepsy (Jin et al., 2000). Similarly, picrotoxin-induced generalized tonic-clonic seizures give rise to BK<sub>Ca</sub> channel gain-of-function characterized by elevated currents and high-frequency firing in somatosensory (barrel) cortical neurons of pre-sensitized animals (Shrutii et al., 2008). Accordingly, the blockade of BK<sub>Ca</sub> channels suppressed these picrotoxin-induced generalized tonic-clonic seizures (Sheehan et al., 2009). Thus, picrotoxin-induced seizure pre-sensitization may cause a maladaptive regulation (e.g., exit from the endoplasmic reticulum) of BK<sub>Ca</sub> channels in brain neurons. In a fly model of ethanol intoxication/withdrawal, a blockade of Slo1 gene neural promoter prevented the occurrence of ethanol-induced enhancement of electrophysiological seizure susceptibility, suggesting BK<sub>Ca</sub> channel gain-of-function in the pathogenesis of alcohol withdrawal seizures (Ghezzi et al., 2012). However, this report raises some controversy with a rodent model of alcohol withdrawal seizures (N’Gouemo and Morad, 2014).

**CONCLUSION**

The role of BK<sub>Ca</sub> channels in the pathophysiology of diseases of neuronal excitability is complex, in part because the activity of these channels can be regulated by many metabolic factors that alter neuronal excitability, including phosphorylation and acidification. Compelling evidence suggests that BK<sub>Ca</sub> channel loss-of-function and gain-of-function can both contribute to neuronal hyperexcitability that leads to enhanced seizure susceptibility. The identification of BK<sub>Ca</sub> channel subunit mutations has been critical in determining the role of these channels in etiology and mechanisms for epileptogenesis and seizure generation, raising the possibility that BK<sub>Ca</sub> channels may represent potential molecular targets for seizure suppression.
