Abstract

We construct the minimal surface in AdS, relevant for the strong coupling behaviour of local supersymmetric Wilson loops in $\mathcal{N} = 4$ SYM for a closed contour formed out of segments of two intersecting circles. Its regularised area is calculated including all divergent parts and the finite renormalised term. Furthermore we prove that for generic planar curved contours with cusps the cusp anomalous dimensions are functions of the respective cusp angles alone. They do not depend on other local data of the cusps.

Keywords: Wilson loops, AdS/CFT, minimal surfaces, cusp anomalous dimension

(Some figures may appear in colour only in the online journal)

1. Introduction

The renormalisation properties of Wilson loops in perturbative gauge theories have been well understood for a long time [1–5]. With smooth closed contours there appears an exponential of a linear divergence proportional to the length of the contour. Besides removing this factor and the renormalisation of the coupling constant, no further renormalisation is needed to get finite results. This changes if the contour has cusps or self-intersections, where additional logarithmic divergences show up. The corresponding cusp anomalous dimension has been calculated for QCD in one [1], two [6] and three loop order [7].

In $\mathcal{N} = 4$ SYM the situation improves. At first the theory is conformally invariant and the coupling needs no renormalisation, and for local supersymmetric loops the linear divergences cancel [8]. The logarithmic cusp divergences are still present and of great interest for many applications, and one can find a recent calculation up to the four loop order in planar $\mathcal{N} = 4$ SYM in [9].
But even more important, with the AdS/CFT correspondence one has a handle to the strong coupling behaviour. At strong \(\lambda\) 't Hooft coupling, the locally supersymmetric Wilson loop for a closed contour \(\mathcal{C}\) is in leading order given by \([10, 11]\)

\[
W(\mathcal{C}) = \exp\left(-\frac{\sqrt{A}}{2\pi} A(\mathcal{C})\right).
\]

\(A(\mathcal{C})\) is the area of a minimal surface extending into the bulk of AdS$_5$ and approaching its boundary along the contour \(\mathcal{C}\). The construction uses Poincaré coordinates

\[
ds^2 = \frac{1}{r^2} (dx^\mu dx_{\mu} + dr^2),
\]

where the conformal boundary is at \(r = 0\). The UV divergences of the gauge theory reappear as divergences due to the blow up of the metric near \(r = 0\). The standard procedure to define a regularised area \(A\) is based on cutting off that part of the surface on which \(r < \epsilon\).

For the interpolation between weak and strong coupling, integrability techniques have been used in \([12]\) to derive a set of equations for the cusp anomalous dimension.

Solving the minimal surface condition (equation of motion, if seen as string surface) near the boundary of AdS, one gets for space-like contours \([13, 14]\)

\[
x^\mu(\sigma, r) = x^\mu(\sigma, 0) + \frac{1}{2} \frac{d^2}{d\sigma^2} x^\mu(\sigma, 0) r^2 + \mathcal{O}(r^3),
\]

where \(\sigma\) together with the fifth AdS coordinate \(r\) parameterises the surface and is the length parameter on the boundary curve \(x^\mu(\sigma, 0)\). The absence of a term linear in \(r\) in equation (3) ensures that for smooth boundary curves with their bounded curvature one gets (\(l\) is the length of the Wilson loop contour)

\[
A_\epsilon = \frac{l}{\epsilon} + A_{\text{ren}} + \mathcal{O}(\epsilon).
\]

The invariance of \(A_{\text{ren}}\) under conformal rescalings of the metric on the boundary of AdS has been proven in \([13]\). The equivalent issue of keeping the metric fixed, but performing an active conformal mapping of the boundary points, has been discussed on the level of infinitesimal transformations in \([15]\). A direct proof for finite transformations can be given by using (3) and applying Stokes’ theorem on that part of the original surface bounded by the line \(r = \epsilon\) and the preimage of the line which is at the same value of \(r\) on the mapped surface.

In the presence of cusps the expansion in (3) with uniformly bounded coefficients breaks down. This is the reason for the appearance of logarithmic divergences in \(A_\epsilon\) for \(\epsilon \to 0\). For a generic smooth contour with \(n\) cusp one commonly expects\(^1\)

\[
A_\epsilon = \frac{l}{\epsilon} + \sum_{i=1}^{n} \Gamma_{\text{cusp}}(\theta_i) \log \epsilon + A_{\text{ren}} + \mathcal{O}(\epsilon).
\]

Now we are ready to pose the question which will be addressed in this paper. All calculations of the coefficient in the logarithmic divergence have been performed for a cusp with straight legs \([8, 19]\), and it is commonly believed that the above structure, with the same \(\Gamma_{\text{cusp}}\) depending only on the cusp angles \(\theta_i\), is true also for cusps with curved legs. We want to prove that this belief is indeed justified. Of course, it is clear that \(\Gamma_{\text{cusp}}\) can depend on

\(^1\) To match the above mentioned absence of linear divergences in the small coupling expansion one has to understand the area \(A\) in the regularised version of (1) already after subtracting the \(l/\epsilon\) term. This can be understood as the effect of a certain Legendre transformation [8].
dimensionless local data only. But for generic cusps there are available, besides the angles, e.g. the quotients of the right and left limits of the curvature.

In the case of the field theoretic small coupling expansion the use of the simplification achieved by working with straight legs is easier to justify. In comparison to the smooth case, these divergences are due to the change generated by the cusp into the projection of four-dimensional distances \((x - y)^2\) onto the one-dimensional contour parameter space.

The paper is organised as follows. In section 2 we calculate \(A_\theta\) for contours formed out of segments of two intersecting circles with arbitrary radii, including all divergent terms as well as \(A_{\text{ren}}\). The result for this example will fit into the structure (5).

Section 3 is devoted to generic contours in an Euclidean plane. A suitable surface parameterisation for generic cusps with curved legs is developed as some kind of perturbation of that used in the case of straight legs in [8]. Then on its basis a general proof will be given.

Several technical details are collected in six appendices.

### 2. Contour with two cusps, formed by segments of two circles

Two straight half-lines, starting on the \(x_1\)-axis at \(x_1 = q > 0\) with angles \(\gamma_1 < \gamma_2\), form a cusp with angle \(^2\theta = \gamma_2 - \gamma_1\).  

The corresponding minimal surface is given by [8]

\[
x_1 = q + \rho \cos(\varphi + \gamma_1), \quad x_2 = \rho \sin(\varphi + \gamma_1), \quad r = \frac{\rho}{f(\varphi)}.
\]

with \(0 \leq \rho < \infty, \quad 0 \leq \varphi \leq \theta\). The essential properties of this solution are summarised in appendix B, in particular \(f(\varphi)\) is defined implicitly by equations (77), (78).

The map

\[
x_\mu \mapsto y_\mu = \frac{x_\mu}{x^2 + r^2}, \quad r \mapsto z = \frac{r}{x^2 + r^2}
\]

is an isometry inside AdS and acts as a conformal transformation on the boundary (inversion at the unit circle). It maps the two half-lines discussed above to segments of two circles forming a closed contour with two cusps, both with angle \(\theta^3\). For some details see appendix A.

Due to the bulk isometry property of (8), the minimal surface related to this closed contour is then given by

\[
y_1 = \frac{\rho \cos(\varphi + \gamma_1) + q}{\rho^2 + q^2 + 2q\rho \cos(\varphi + \gamma_1) + (\rho/f(\varphi))^2},
\]

\[
y_2 = \frac{\rho \sin(\varphi + \gamma_1)}{\rho^2 + q^2 + 2q\rho \cos(\varphi + \gamma_1) + (\rho/f(\varphi))^2},
\]

\[
z = \frac{\rho/f}{\rho^2 + q^2 + 2q\rho \cos(\varphi + \gamma_1) + (\rho/f(\varphi))^2}.
\]

For all surfaces we follow the standard definition of the regularised area, i.e. cutting off that part of the surface whose Poincaré \(r\)-coordinate (see (2)) is smaller than \(\epsilon\). Since we

\(^2\) We follow the convention used in [8], i.e. smooth case corresponds to \(\theta = \pi\).

\(^3\) A similar construction in the context of BPS Wilson loops composed of two longitudes on a \(S^2\) has been used in [16].
denoted this coordinate for our surface generated by the map (8) with the letter \( z \), we have to calculate

\[
A_\epsilon = \int_{\varphi_\epsilon^+}^{\varphi_\epsilon^-} \sqrt{h} \ d\varphi,  
\]

(10)

where \( h \) is the determinant of the induced metric on the surface (9). There is an alternative way to get the same quantity: calculate the area of the preimage of the cut surface on the original (7). Then for \( h \) one has to take the simple form as in (75) of appendix B and the integration region for \( \rho \) at fixed allowed \( \varphi \) is given by

\[
\rho_- < \rho < \rho_+,  
\]

(11)

with

\[
\rho_\pm = \frac{1 - 2 \epsilon \varphi(\varphi) \cos(\varphi + \gamma_1) \pm \sqrt{1 - 4 \epsilon \varphi(\varphi) \cos(\varphi + \gamma_1) - 4 \epsilon^2 q^2 f^2 \sin^2(\varphi + \gamma_1) - 4 \epsilon^2 q^2}}{2 \epsilon (f + 1/f)}  
\]

denoting the two solutions of the equation \( z = \epsilon \). The square root in the above formula has to be real. This gives implicit bounds for \( \varphi \) via

\[
f_0 < f(\varphi) < f_\epsilon.  
\]

(12)

To characterise \( f_\epsilon \), one has to handle the fact that the relation between \( \varphi \) and \( f \) is not one to one. Instead we have \( f(\varphi) = f(\theta - \varphi) \), and in \( \varphi \in (0, \theta/2) \) the function \( f(\varphi) \) is given by formula (78) of appendix B. Therefore, we split the regularised area \( A_\epsilon \) into two pieces, one originating from \( \varphi \in (0, \theta/2) \) and the other from \( \varphi \in (\theta/2, \theta) \)

\[
A_\epsilon = A^{(1)}_\epsilon + A^{(2)}_\epsilon.  
\]

(13)

Having in mind \( \varphi + \gamma_1 = \gamma_2 - (\theta - \varphi) \), we define \( f^{(j)}_\epsilon (j = 1, 2) \) by

\[
f^{(j)}_\epsilon = \frac{\sqrt{1 - 4 \epsilon q^2 \sin^2(\gamma_j \pm \varphi(f^{(j)}_\epsilon))} - \cos(\gamma_j \pm \varphi(f^{(j)}_\epsilon))}{2 \epsilon q \sin^2(\gamma_j \pm \varphi(f^{(j)}_\epsilon))}.  
\]

(14)

Estimating this implicit definition for \( \epsilon \to 0 \), which is correlated with \( f^{(0)}_\epsilon \to \infty \) and via (81) with \( \varphi(f^{(0)}_\epsilon) \to 0 \) this simplifies to

\[
f^{(j)}_\epsilon = \frac{T_j}{\epsilon} - q + O(\epsilon) \quad \text{with} \quad T_j = \frac{1 - \cos \gamma_j}{2 q \sin^2 \gamma_j}.  
\]

(15)

After substituting the integration variables \( \varphi \) or \( \theta - \varphi \), respectively, via (78) of appendix B by \( f \), we get for \( j = 1, 2 \)

\[
A^{(j)}_\epsilon = \int_{\rho_-}^{\rho_+} df \int_{\rho(\varphi)}^{\rho(f)} \frac{d\rho}{\rho} \sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2}}  
\]

\[
= \int_{\rho_-}^{\rho_+} df \sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2}} \left( 2 \log \frac{\rho^{(0)}_\epsilon(f)}{q} + \log \frac{1 + f^2}{f^2} \right),  
\]

(16)

where we used that (11) implies \( \rho^{(1)}_\pm \rho^{(0)} = \frac{q^2 f^2}{1 + f^2} \). Here \( \rho^{(1)}_\pm \) is given by the rhs of (11) and \( \rho^{(2)}_\pm \) after the replacement of \( \gamma_1 + \varphi(f) \) by \( \gamma_2 - \varphi(f) \).
Let us now separate $A^{(j)}_e$ into two additive pieces, where only the first one contains the function $\varphi(f)$

$$A^{(j)}_e = A^{(j,1)}_e + A^{(j,2)}_e,$$  \hfill (17)

$$A^{(j,1)}_e = 2 \int_{f_0}^{f_0} df \sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2}} \log N^{(j)}_e(q, f).$$  \hfill (18)

$$A^{(j,2)}_e = - \int_{f_0}^{f_0} df \sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2}} \left(2 \log(2q\epsilon) + \log(1 + f^2)\right).$$  \hfill (19)

$N^{(j)}_e(q, f_0, f)$ is the nominator in (11), i.e.

$$N^{(j)}_e(q, f) = 1 - 2\epsilon q f \cos\left(\varphi(f) \pm \gamma\right)$$

$$+ \sqrt{1 - 4\epsilon q f \cos\left(\varphi \pm \gamma\right) - 4\epsilon^2 q^2 f^2 \sin^2(\varphi \pm \gamma) - 4\epsilon^2 q^2}.$$  \hfill (20)

The straightforward evaluation of $A^{(j,2)}_e$ gives, using (15) and (86),

$$A^{(j,2)}_e = \Gamma_{\text{cusp}}(\theta) \log(2q\epsilon) + \frac{1 - \cos \gamma_j}{\epsilon q \sin^2 \gamma_j} \left(1 - \log\left(\frac{1 - \cos \gamma_j}{\sin^2 \gamma_j}\right)\right)$$

$$- \int_{f_0}^{1} df \left(\sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2}} - 1\right) \log(1 + f^2) + 2q \log(2q\epsilon f)$$

$$+ f_0 \log(1 + f_0) + 2 \arctan f_0 - f_0 - \pi + O(\log \epsilon).$$  \hfill (21)

The bit more involved evaluation of $A^{(j,1)}_e$ is discussed in some detail in appendix C, with the result given in (97). Making use of the definition of $\Gamma_{\text{cusp}}(\theta)$ in equation (86) of appendix B it appears as

$$A^{(j,1)}_e = \frac{2}{q\epsilon} \left(\frac{\gamma_j}{2 \sin \gamma_j} - \frac{1 + \log\left(1 + \cos \gamma_j\right)}{4 \cos^2 \gamma_j}\right)$$

$$- \Gamma_{\text{cusp}}(\theta) \log 2 - 2q \log\left(\frac{1 - \cos \gamma_j}{\sin^2 \gamma_j}\right) + o(1),$$  \hfill (22)

and then the sum (17) is

$$A^{(j)}_e = \Gamma_{\text{cusp}}(\theta) \log(q\epsilon) + \frac{\gamma_j}{\epsilon q \sin \gamma_j} + f_0 \log(1 + f_0^2) + 2 \arctan f_0 - 2f_0 - \pi$$

$$- \int_{f_0}^{1} df \left(\sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2}} - 1\right) \log(1 + f^2) + o(1).$$  \hfill (23)

To perform the ambiguous separation into a divergent and finite part we have to introduce an RG-scale $\mu$. Then we get for the total area (13)

$$A_e = 2\Gamma_{\text{cusp}}(\theta) \log(\mu\epsilon) + \frac{l}{\epsilon} + O(1).$$  \hfill (24)
Here we have made use of appendix A, equation (72) to also confirm for this explicit example the generic property, that the factor for the linear divergence is given by the length of the contour.

The renormalised area is \( Q = 1/\rho \) distance between the cusps, see (66)

\[
A_{\text{ren}} = - 2 \Gamma_{\text{cusp}}(\theta) \log (\rho Q) + 2f_0 \log (1 + f_0^2) + 4 \arctan f_0 - 4f_0^2 - 2\pi \\
- 2 \int_{f_0}^{\infty} \, df \left( \frac{f^4 + f_0^2}{f^4 + f_0^2 - f_0^4 - f_0^2} - 1 \right) \log (1 + f^2). 
\]  

(25)

It has a remarkable structure. There is a conformally invariant contribution depending only on the cusp angle \( \theta \), via \( f_0(\theta) \) given in (79). Dependence on other data of our contour appear only via the first term, whose presence is enforced by the RG-ambiguity and which breaks conformal invariance. There this dependence comes via the distance between the two cusps \( Q \), which by (66) and (69) is given as a function of the radii of the two circles and the distance of their centres.

Since the linear divergence is \( 1/\epsilon \), perhaps the most natural choice for the RG scheme is minimal subtraction with respect to \( 1/\epsilon \). This corresponds to \( \mu = 1/l \). Then \( A_{\text{ren}} \) depends on the cusp angle \( \theta \) and the ratio \( Q/l \).

Closing this section, let us consider the limit in which our contour becomes a circle. Then one has \( \theta = \pi \), i.e \( f_0 = 0 \) and \( Q = 2R \). Since \( \Gamma_{\text{cusp}}(\pi) = 0 \), this gives

\[
A_{\text{ren}}^{\text{circle}} = -2\pi , 
\]  

(26)

in agreement with the literature \([8, 17, 18]\).

3. Cusp anomalous dimension in the generic case

Let us consider a closed contour in the \((x_1, x_2)\)-plane with a cusp, located at the origin, but smooth otherwise. At first we divide the related minimal surface in two parts, depending on whether \( x_1^2 + x_2^2 \) is smaller or larger then a certain value. This \( \rho_0 \) should be small, but kept fixed for \( \epsilon \to 0 \). The corresponding regularised area is then given by

\[
A_{\epsilon} = A_{\epsilon}^{\text{cusp}}(\rho_0) + A_{\epsilon}^{\text{smooth}}(\rho_0). 
\]  

(27)

Due to the general result for smooth contours we know already

\[
A_{\epsilon}^{\text{smooth}}(\rho_0) = \frac{l - l_{\rho_0}}{\epsilon} + \mathcal{O}(1), 
\]  

(28)

where \( l \) is the length of the total contour and \( l_{\rho_0} \) that of the cusp piece.

Let now the two curved legs of the cusp be parameterised in the vicinity of the origin by

\[
x_1^{(j)} = \rho \cos (\phi_j(\rho)), \quad x_2^{(j)} = \rho \sin (\phi_j(\rho)), \quad j = 1, 2. 
\]  

(29)

The cusp angle \( \theta \) is then given by

\[
\theta = \phi_2(0) - \phi_1(0), 
\]  

(30)

and the \( \rho \to 0 \) limits of the curvatures of both legs are

\[
k_j = 2c_j = 2 \frac{d\phi_j}{d\rho} \bigg|_{\rho=0}. 
\]  

(31)
The length $l_{0}$ turns out to be
\[ l_{0} = 2\rho_{0} + \frac{1}{6}(c_{1}^{2} + c_{2}^{2})\rho_{0}^{3} + \mathcal{O}(\rho_{0}^{4}). \] (32)

For the evaluation of $A_{\text{cusp}}(\rho_{0})$ we want to work with coordinates $\rho, \varphi$ for the $(x_{1}, x_{2})$-plane, adapted in a manner that still $\rho^{2} = x_{1}^{2} + x_{2}^{2}$, but that the lines of constant $\varphi = 0$ and $\varphi = \theta$, respectively, agree with the curved legs forming the cusp. The first requirement is realised by the structure
\[ x_{1} = \rho u(\rho, \varphi) \quad x_{2} = \rho \sqrt{1 - u^{2}}, \] (33)
and the second one means in addition
\[ u(\rho, 0) = \cos(\phi^{(1)}(\rho)) \quad u(\rho, \theta) = \cos(\phi^{(2)}(\rho)). \] (34)

The additional AdS-coordinate $r$ we parameterise by
\[ r = \rho F(\rho, \varphi), \] (35)
with the boundary condition
\[ F(\rho, 0) = F(\rho, \theta) = 0. \] (36)

Then the regularised area of the cusp piece is given by
\[ A_{\text{cusp}}(\rho_{0}) = \int_{r > r_{0}, \rho < \rho_{0}} L(\rho, \varphi)\, d\rho \, d\varphi, \] (37)
with
\[ L(\rho, \varphi) = \sqrt{\frac{F^{2}(1 - u^{2} + \rho^{2}u^{2}) + (1 + (F + \rho F')^{2})u^{2} - 2\rho F'F + \rho F'\mu u'}{\rho^{2}F^{4}(1 - u^{2})}}. \] (38)

We will look for perturbative solutions of the related equation of motion\(^{5}\) in the form
\[ F(\rho, \varphi) = F_{1}(\varphi) + \rho F_{2}(\varphi) + \ldots, \] (39)
with the boundary conditions
\[ F_{n}(0) = F_{n}(\theta) = 0 \quad n = 1, 2, \ldots. \] (40)

As a more concrete form for $u$ we now take
\[ u(\rho, \varphi) = \cos\left(\frac{\rho s(\varphi) + \varphi}{\theta} \left(\phi_{2}(\rho) - \phi_{1}(\rho)\right) + \phi_{1}(\rho)\right). \] (41)
where the function $s(\varphi)$ has to be chosen with the behaviour
\[ s(\varphi) = a_{1}\varphi^{2/3} + \ldots \quad \varphi \rightarrow 0, \]
\[ s(\varphi) = a_{2}(\theta - \varphi)^{2/3} + \ldots \varphi \rightarrow \theta. \] (42)

The $a_{j}$ are constants to be fixed later.

Let us stop for a moment in order to comment on the need for this peculiar $s(\varphi)$. Naively one would of course start with $s(\varphi)$ put to zero in (41). But then, as we will see below, the boundary condition (40) for $F_{2}$ cannot be fulfilled. For more intuitive arguments for this

---

4 A dot means a derivative w.r.t. $\rho$, a prime w.r.t. $\varphi$.

5 i.e. the Euler–Lagrange equation obtained by varying $F$. Since $u$ is a building block for the specification of the coordinate system, it is kept fixed in this process.
ansatz, beyond this a posteriori justification, see appendix D. There one also finds in figure D1 a visualisation of the difference of coordinates with and without \( s(\varphi) \).

The variational derivative of (38) with respect to \( F \) appears as a quotient. We take as the equation of motion the vanishing of the nominator, insert (41) and expand the result with respect to \( \rho \). Then the condition, that in this expansion the coefficients of the leading and nextleading term vanish, leads to

\[
2(F_1')^2 + (1 + F_1^2)(2 + F_1^2 + F_1F_2') = 0
\]  
and

\[
F_2''(\varphi) + G_1(\varphi)F_1' + G(\varphi)F_2 + M(\varphi) = 0,
\]
in which \( ^6 \)

\[
M(\varphi) = \frac{-1}{\theta(F_1 + F_1^2)} \left\{ \theta(F_1 + F_1^2)F_1' s''(\varphi) + (c_1(\theta - \varphi) + c_2 \varphi + \theta s(\varphi)) \left( 2F_1 F_1' + 7 + 3F_1^2 \right) + (c_1 - c_2 - \theta s'(\varphi)) \left( 1 + F_1^2 \right) \left( 6 + 3F_1^2 + 2(F_1')^2 + F_1 F_2'' \right) \right\}.
\]

As expected, the leading order equation (43) depends on \( F_1 \) only. Moreover, it equals that for the full \( F \) in the case with straight legs, see (84). Therefore we know from appendix B \( F_1(\varphi) = F_1(\theta - \varphi) \) and in particular from equation (82)

\[
F_1(\varphi) = a \varphi^{1/3} + \frac{a^3}{5} \varphi + \mathcal{O}(\varphi^{5/3}) \quad a = (3/E)^{1/3}.
\]

Since our concern are divergent contributions to the regularised area

\[
A_\epsilon = \int_{|F(\rho, \varphi)| > \epsilon} L(\rho, \varphi) d\rho d\varphi
\]
for \( \epsilon \to 0 \), we also have to control the behaviour of \( F_2 \) near the AdS boundary. We will do this for \( \varphi \to 0 \), the case \( \varphi \to \theta \) looks similarly. From (42) and (48) we get for \( \varphi \to 0 \)

\[
M(\varphi) = \frac{2(a a_1 - a^3 c_1)}{27 \varphi^2} + \frac{8(2a^3 a_i - a^3 c_1)}{135 \varphi^{4/3}} + \mathcal{O}(1/\varphi),
\]

\[
G(\varphi) = \frac{-2}{9 \varphi^2} - \frac{28 a^2}{45 \varphi^{4/3}} + \mathcal{O}(\varphi^{-2/3}).
\]

\( ^6 \) A term, vanishing due to the leading order equation (43) for \( F_1 \), has been omitted already in the expression for \( M \). \( c_j \) defined in (31).
Due to this type of singular behaviour of its coefficient functions, the differential equation for $F_2(\phi)$ is singular at $\phi = 0$. Since $\phi^3 M$, $\phi^2 G$ and $\phi G_1$ are analytic in $x = \phi^{1/3}$, we have a regular singular point, and $F_2$ can be represented as a Frobenius series in $x$. Inserting the leading plus next leading terms for $G$, $G_1$ and $M$ from (50)–(52) into (44) one gets ($B_1$, $B_2$ integration constants)

$$F_2(\phi) = \frac{1}{3} (a_1 - a^2 c_1) - \frac{4a^3 a_1 - 2a^5 c_1}{15} \phi^{2/3} + O(\phi)$$

$$+ B_1 \left( \phi^{-2/3} + \frac{8}{5} \theta^2 + O(\phi^{2/3}) \right) + B_2 \left( \phi^{1/3} + a^2 \phi + O(\phi^{5/3}) \right).$$

This expression contains three so far unfixed parameters of quite different origin. $a_1$ specifies the choice of the coordinate system and $B_1$ and $B_2$ are the free parameters in the general solution of the differential equation. Now the boundary condition $F_2(0) = 0$ requires first of all $B_1 = 0$ in order to prevent a divergence. But then there is still the first term on the rhs of (53) obstructing the boundary condition. It vanishes only for the choice

$$a_1 = a^2 c_1.$$  

As announced above, we see that without $s(\phi)$ in (41) the boundary condition for $F_2$ cannot be fulfilled, if the corresponding leg of the cusp is curved.7 Fixing $B_2$ (and $a_2$ in (42)) is a matter of the boundary condition on the second leg of the cusp.

To analyse the regularised area (49), we expand $L(\rho, \phi)$ with respect to $\rho$

$$L(\rho, \phi) = \frac{1}{\rho} L_1(\phi) + L_2(\phi) + O(\rho).$$

Then we get with (38), (39), (41)

$$L_1(\phi) = \sqrt{1 + F_1^2 + \left( F_1' \right)^2},$$

$$L_2(\phi) = \frac{1}{\theta F_1^3 \sqrt{1 + F_1^2 + \left( F_1' \right)^2}} \left\{ \left( c_2 - c_1 + \theta s'(\phi) \right) \left( F_1 + F_1' \right) \right. $$

$$- \left( c_1 (\theta - \phi) + c_2 \phi + \theta s(\phi) \right) F_1^2 F_1' - 2 \theta \left( 1 + \left( F_1' \right)^2 \right) F_2 + \theta F_1 F_1' F_2 \right\}. $$

Due to the asymptotics (48) this means for $\phi \to 0$

$$L_1(\phi) = \frac{a}{3 \alpha \phi^{2/3}} + \frac{a}{15 \phi^{2/3}} + O(1),$$

7 We have given already arguments for $2/3$ as the exponent in (42). As an interesting aside one can perform the analysis with a generic exponent $b$. Then the leading term for $M(\phi)$ in (50) turns out to be $\infty \phi^{b-1/3}$ for $b < 2/3$. It is $\infty \phi^{2/3}$ for $b > 2/3$, but with a nonzero coefficient (as soon as $c_1 = 0$), independent of the choice of $a_1$. 

and via (48), (53) and (54)

\[ L_2(\varphi) = -B_2 \left( \frac{1}{3a_2^2 \varphi^2} + B_1 \left( \frac{1}{\varphi^{2/3}} \right) \right) + \frac{c_1}{a \varphi^{1/3}} + O(1). \] \quad (59)

If \( B_2 \neq 0 \), the integral of \( L_2(\varphi) \) is still divergent. The further analysis would be simpler if we could put \( B_2 = 0 \). But, as mentioned already and elaborated in more detail in appendix E, fixing \( B_2 \) is a matter of the boundary condition on the second leg \((\varphi \to \theta)\), and for generic situations we have to live with \( B_2 \neq 0 \).

The divergences in (37) arise from the neighbourhood of \( \rho = 0 \), \( \varphi = 0 \) and \( \varphi = \theta \). To keep them under control with the above estimates, we write

\[ A_c^{\text{cusp}}(\rho_0) = A_c^{\rho=0}(\rho_0) + A_c^{\theta}(\rho_0) \] \quad (60)

and understand the first term on the rhs with the \( \varphi \)-integration over the interval \((0, \theta/2)\) and the second one over \((\theta/2, \theta)\). Then one has for the second order contribution to \( A_c^{\rho=0}(\rho_0) \)

\[
A_c^{\rho=0}(\rho_0) = \int_{\rho < \rho_0} B_2 \int_{\rho_{\text{min}}(\epsilon)}^{\rho_0} d\rho \rho \int_{\rho_{\text{min}}(\epsilon)}^{\rho_0/2} d\varphi L_2(\varphi) d\rho d\varphi \\
= \frac{B_2}{2a^2} \int_{\rho_{\text{min}}(\epsilon)}^{\rho_0} d\rho \int_{\rho_{\text{min}}(\epsilon)}^{\rho_0/2} d\varphi \frac{\varphi^{1/3}}{\varphi^{1/3} + O(\rho') = \epsilon} + O(1) \\
= \frac{1}{\epsilon} \left( \frac{B_2}{2a^2} \rho_0^2 + \frac{B_2^2}{3a^2} \rho_0^3 + O(\rho_0^4) \right) + O(1). \] \quad (61)

Use has been made of (59) and \( \rho_{\text{min}} = O(\epsilon) \).

The integrand of the leading order contribution \( A_c^{\rho=1}(\rho_0) \) is the same as for the case with a cusp between straight legs. However, the integration region depends also on \( F_2 \). From (120) in appendix F we can take

\[
A_c^{\rho=1}(\rho_0) = \int_{\rho < \rho_0} B_2 \int_{\rho_{\text{min}}(\epsilon)}^{\rho_0} d\rho \rho \int_{\rho_{\text{min}}(\epsilon)}^{\rho_0/2} d\varphi L_1(\varphi) d\rho d\varphi \\
= \frac{1}{\epsilon} \left( \rho_0 + \frac{B_2}{2a} \rho_0^2 + O(\rho_0^3) \right) + \frac{1}{2} \Gamma_{\text{cusp}}(\theta) \log \epsilon + O(1). \] \quad (62)

Note that the \( 1/\epsilon \) terms proportional to \( \rho_0^2 \) in the sum of (61) and (62) cancel. Repeating the same estimates\(^8\) for \( A_c^{\theta}(\rho) \) we get with (60)–(62)

\[ A_c^{\text{cusp}}(\rho_0) = \frac{1}{\epsilon} \left( 2\rho_0 + O(\rho_0^3) \right) + \Gamma_{\text{cusp}}(\theta) \log \epsilon + O(1), \] \quad (63)

and finally with (27), (28), (32) and (63)

\[ A_c = \frac{1}{\epsilon} + \Gamma_{\text{cusp}}(\theta) \log \epsilon + O(1). \] \quad (64)

Why we are sure that the \( O(\rho_0^3) \) terms present in \( A_c^{\text{cusp}}(\rho_0) \) and \( A_c^{\text{smooth}}(\rho_0) \) cancel each other? If we \textit{a priori} assume, that \( A_c \) has an asymptotic expansion with just an \( 1/\epsilon \) and \( \log \epsilon \) singular term, then it follows due to the uniqueness of asymptotic expansions and the absence of any \( \rho_0 \)-dependence in \( A_c \) itself. Without this assumption, we can rely on the fact that the \( \epsilon \)-expansions of both \( A_c^{\text{cusp}}(\rho_0) \) and \( A_c^{\text{smooth}}(\rho_0) \) are valid uniformly in a certain interval for \( \rho_0 \). Then the difference of the resulting expansion for \( A_c \) at two different values of \( \rho_0 \) is an

\(^8\) Then \( B_2 \) has to be replaced by \( \hat{B}_1 = v_1(\theta) \), see appendix E.
expansion of zero with necessarily zero coefficients, and this just proves the stated
\( \rho_0 \)-independence.

To complete the proof, we still have to comment on the effect of \( F_3 \) and higher orders in
(39). For this purpose it is not necessary to continue order by order the tedious derivation of
the corresponding differential equations and their asymptotic estimates for \( \varphi \to 0 \). Instead,
we argue that \( F (\rho, \varphi) \) as a whole has to behave like \( \varphi^{1/3} \) for all fixed \( \rho > 0 \), to fit the
asymptotic information contained in (3). Then (38) implies \( L (\rho, \varphi) \propto \varphi^{-4/3} \) and conse-
quently \( L_n (\varphi) \propto \varphi^{-4/3} \) for all \( n \). The contribution of \( L_n \) to \( A_{\text{cusp}} (\rho_0) \) is
\[
\int_{\rho < \rho_0, \ pF (\rho, \varphi) > \epsilon} \rho^{n-2} L_n d\rho d\varphi.
\]
Obviously, for \( n \geq 3 \) it does not contribute to the logarithmic divergence. By analogous
arguments as above for the \( L_2 \) contribution, its \( \rho_0 \) dependent contribution to the \( 1/\epsilon \) term just
cancels the corresponding \( \rho_0 \) dependence in \( A_{\text{smooth}} (\rho_0) \).

4. Conclusions

Concerning our calculation of the regularised area \( A_c \) for a minimal surface related to Wilson
loops for contours formed by segments of intersecting circles, two points should be
emphasised. The usual calculation for a cusp formed by two straight half-lines needs both an
UV cutoff \( r > \epsilon \) as well as an IR cutoff \( L \) with the result given in (85). There \( \Gamma_{\text{cusp}} \) appears
both as the factor in front of the logarithmic UV divergence due to the cusp as well as the
factor (with a minus sign) of the logarithmic IR divergence due to the infinite extension of the
half-lines.

Our calculation in section 2 is the first example of an explicit calculation of the minimal
surface and its area \( A_c \) for a curved contour with cusps closed in a finite domain\(^9\). It has two
cusps with equal angles and needs no IR regularisation. As the coefficient of the linear UV
divergence we get the length of the contour as required by the general theory for smooth
contours. For the logarithmic divergence we get the expected factor \( 2 \Gamma_{\text{cusp}} \). The renormalised
area in a most natural minimal subtraction scheme turns out to be a function of the cusp angle
and the ratio of the distance of the cusps to the length of the contour.

Furthermore, with the case just discussed we have at hand an example, which confirms
the expectation, that the cusp anomalous dimension depends only on the cusp angle, and also
in cases where the legs of the cusp are curved. This has then been verified in section 3 for the
larger class of generic cusped contours in a Euclidean plane. One by-product of the technique
developed for this purpose could be the use of numerical solutions of the differential equation
in appendix E for control over the next leading contribution in a perturbative construction of
the surface in the vicinity of the cusp.

To cover full generality beyond planar contours one has to repeat our analysis, but now
with additional functions of \( \rho \) and \( \varphi \), which describe the extension of the surface in the
directions of \( x_0 \) and \( x_3 \).

\(^9\) The only other finite cusped contours with explicitly known surface are the null tetragon [20] and a certain
degenerated null hexagon [21], both relevant for scattering amplitudes. But there the contour is straight, away from
the cusps. For progress in surface construction related to smooth boundary curves see e.g. [22] and references therein.
Acknowledgments

I would like to thank Danilo Diaz, Nadav Drukker, Hagen Münkler and in particular George Jorjadze for useful discussions.

Appendix A

Here we want to provide the elementary geometric formulas related to the conformal mapping of two crossing circles to two crossing straight lines.

Under an inversion

\[ y = \frac{x_C}{x^2} \quad \iff \quad x = \frac{y_C}{y^2} \quad (65) \]

two straight lines in the \((x_1, x_2)\)-plane, crossing the \(x_1\)-axis at \(x_1 = q > 0\) with angles \(\gamma_1\) and \(\gamma_2\), respectively, are mapped to two circles in the \((y_1, y_2)\)-plane, crossing at the origin and at \((1/q, 0)\). Hence the distance between the two crossing points is

\[ Q = \frac{1}{q^2}. \quad (66) \]

The radii of the circles are

\[ R_j = \frac{1}{2q \sin \gamma_j}, \quad (67) \]

and the centres of the circles are located at

\[ \left( \frac{1}{2q} \left(1, \cot \gamma_j \right) \right) \quad j = 1, 2 \]

respectively. The distance between the two centres is

\[ D = \frac{1}{2q} |\cot \gamma_1 - \cot \gamma_2|. \quad (68) \]

Inverting (67), (68), one gets \(q\) and the \(\gamma_j\) in terms of \(D\) and the \(R_j\)

\[ q = \frac{D}{\sqrt{2D^2 \left( R_1^2 + R_2^2 \right) - D^4 - \left( R_1^2 - R_2^2 \right)^2}}, \]

\[ |\sin \gamma_j| = \frac{\sqrt{2D^2 \left( R_1^2 + R_2^2 \right) - D^4 - \left( R_1^2 - R_2^2 \right)^2}}{2DR_j}. \quad (69) \]

With the convention \(R_1 \geq R_2\), these formulas are valid in the full range

\[ R_1 - R_2 \leq D \leq R_1 + R_2. \quad (70) \]

Obviously, beyond these bounds there is no crossing. Let us also note that (69) and (70) imply

\[ |\sin \gamma_1| \leq \frac{R_2}{R_1}, \quad |\sin \gamma_2| \leq 1. \quad (71) \]
The length of the contour, formed by the two segments of the crossing circles is

\[
I = \frac{1}{q} \left( \frac{\gamma_1}{\sin \gamma_1} + \frac{\gamma_2}{\sin \gamma_2} \right) .
\] (72)

Let us now consider two rays (i.e. two halves of the straight lines of the previous discussion), starting on the \(x_1\)-axis at \((q, 0)\) with \(q = 0.5\). Note the difference in scale between the first and second line.

**Figure A1.** The four closed contours (blue) with cusps, formed out of circular segments, as images of rays (black), starting at \((q, 0)\) with \(q = 0.5\). Note the difference in scale between the first and second line.

The length of the contour, formed by the two segments of the crossing circles is

\[
I = \frac{1}{q} \left( \frac{\gamma_1}{\sin \gamma_1} + \frac{\gamma_2}{\sin \gamma_2} \right).
\] (72)

Let us now consider two rays (i.e. two halves of the straight lines of the previous discussion), starting on the \(x_1\)-axis at \((q, 0)\). Their images under (65) form the boundary of a compact region with two cusps. For this we have four possibilities, two of these regions are convex and two not convex, see figure A1.

**Appendix B**

In this appendix we review the calculation for a cusp with straight legs based on [8, 19]. Furthermore, we present an alternative representation of the cusp anomalous dimension in terms of a hypergeometric function and comment on a parameterisation of the problem, more convenient for our discussion in the main text.

Due to the dilatation symmetry of a cusp located at the origin between two *straight* legs extending to *infinity*, one can describe the \(r\)-coordinate of the string surface by the ansatz
where $\rho, \varphi$ are polar coordinates in the $(x_1, x_2)$-plane of the AdS boundary at $r = 0$, i.e.

$$x_1 = \rho \cos \varphi \quad x_2 = \rho \sin \varphi. \quad (74)$$

Then the determinant of the induced metric on the surface turns out to be

$$h = \frac{f^4 + f^2 + (f')^2}{\rho^2}, \quad (75)$$

and, in virtue of this factorisation of the $\rho$ and $\varphi$ dependence, the minimal surface condition (equation of motion) is an ordinary differential equation for $f(\varphi)$ with boundary conditions $f(0) = f(\theta) = \infty$ ($\theta$ cusp angle)

$$f''(f^4 + f^2) - 2(f')^2(f'+2f^3) - f^3(1 + f^2)(1 + 2f^2) = 0. \quad (76)$$

Instead of solving this second order equation directly, it is more convenient to use the conservation law related to the lack of any explicit $\varphi$-dependence in (75)

$$E = f_0 \sqrt{1 + f_0^2} = \frac{f^4 + f^2}{\sqrt{f^4 + f^2 + (f')^2}}, \quad (77)$$

with $f_0 = f(\theta/2)$ denoting the minimal value of $f$ in $\varphi \in (0, \theta)$. Now integration yields

$$\varphi = E \int_0^\infty \frac{df}{\sqrt{(f^4 + f^2)^2 - E^2(f^4 + f^2)}}, \quad (78)$$

This holds for $0 < \varphi < \theta/2$, and furthermore one has $f(\varphi) = f(\theta - \varphi)$. In particular the equation

$$\theta = \frac{2E}{\int_0^\infty \frac{df}{\sqrt{(f^4 + f^2)^2 - E^2(f^4 + f^2)}}}, \quad (79)$$

fixes the relation between $f_0$ and the cusp angle $\theta$. The function $\theta(f_0)$ is monotonically decreasing, $\theta(0) = \pi$, $\theta(\infty) = 0$. The estimate of this equation and (77) for large $f_0$ yields

$$\theta = \frac{2\pi^{1/2}\Gamma\left(\frac{3}{4}\right)}{\Gamma\left(\frac{3}{2}\right)} f_0^{-1} + \mathcal{O}(f_0^{-3}). \quad (80)$$

Expanding the integrand in equation (78) for large $f$ (but fixed $f_0$) one gets

$$\frac{\varphi}{E} = \frac{1}{3} f^{-3} - \frac{1}{5} f^{-5} + \frac{1}{7} \left(1 + \frac{E^2}{2}\right) f^{-7} + \mathcal{O}(f^{-9}). \quad (81)$$

The inversion of (81) is

$$\frac{1}{f(\varphi)} = \left(\frac{3\varphi}{E}\right)^{1/3} + \frac{1}{5} \cdot \frac{3\varphi}{E} + \frac{6 - 2SE^2}{350} \cdot \left(\frac{3\varphi}{E}\right)^{5/3} + \mathcal{O}(\varphi^{7/3}). \quad (82)$$

For use in the main text we note that

$$F(\varphi) := \frac{1}{f(\varphi)}, \quad (83)$$
defines a function which has an ordinary Taylor expansion in \( x = \varphi^{1/3} \) around \( x = 0 \). Expressing the equation of motion (76) in terms of \( F(\varphi) \) it looks like

\[
2 \left( F' \right)^2 + (1 + F^2) \left( 2 + F^2 + FF'' \right) = 0. \tag{84}
\]

For the regularised area, defined with the cutoffs \( r = \rho / f(\varphi) > \epsilon \) and \( \rho < L \), one gets

\[
A_{c,L} = \int d\rho \, d\varphi \frac{\sqrt{f^4 + f^2 + (f')^2}}{\rho} = \frac{2L}{\epsilon} + \Gamma_{cusp}(\theta) \log \frac{\epsilon}{L} + A_0(\theta) + \ldots. \tag{85}
\]

The dots denote terms vanishing for \( \epsilon \rightarrow 0 \) and

\[
\Gamma_{cusp}(\theta) = 2f_0 - 2 \int_{f_0}^{\infty} \left( 1 + \frac{f^4 + f^2}{\sqrt{f^4 + f^2 - E^2}} - 1 \right) df, \tag{86}
\]

\[
A_0(\theta) = 2f_0 \left( \log f_0 - 1 \right) - 2 \int_{f_0}^{\infty} \log f \left( 1 + \frac{f^4 + f^2}{\sqrt{f^4 + f^2 - E^2}} - 1 \right) df. \tag{87}
\]

The substitution \( f^2 = f_0^2 + z^2 \) yields [19]

\[
\Gamma_{cusp}(\theta) = 2 f_0 \int_{-\infty}^{\infty} \left( 1 - \frac{1 + z^2 + f_0^2}{\sqrt{1 + z^2 + 2f_0^2}} \right) dz. \tag{88}
\]

Based on this integral we found a closed expression in terms of a hypergeometric function

\[
\Gamma_{cusp}(\theta) = \frac{\pi}{2} \frac{f_0^2}{\sqrt{1 + f_0^2}} 2F_1 \left( \frac{1}{2}, \frac{3}{2}, \frac{2}{1 + f_0^2}, -f_0^2 \right). \tag{89}
\]

This implies that \( \Gamma_{cusp} \) for \( \theta \rightarrow \pi \), i.e. \( f_0 \rightarrow 0 \) goes to zero and for \( \theta \rightarrow 0 \) i.e. \( f_0 \rightarrow \infty \) grows linearly in \( f_0 \) with a factor \( \pi^2 \Gamma(1/4) \). Using (79) and (86) for a parametric plot one gets a numerical evaluation of \( \Gamma_{cusp}(\theta) \), see fig. B1.

\[
\text{Figure B1.} \quad \Gamma_{cusp} \text{ as a function of} \theta, \text{ obtained with} f_0 \text{ as parameter in parametric plot.}
\]
Appendix C

This appendix is devoted to the $\epsilon \to 0$ asymptotics of $A^{(j,1)}_\epsilon$, as defined in (18). We start with

$$A^{(j,1)}_\epsilon = 2 \int_{f_0}^{f_0(\epsilon)} df \left( \sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2} - 1} \right) \log N^{(j)}(q, f) + 2 \int_{f_0}^{f_0(\epsilon)} df \log N^{(j)}(q, f).$$

(90)

In the first term of the above equation the factor in big brackets is $O(1/f^4)$ for large $f$. Let us split the integration region into the intervals $(f_0, T_f^{\epsilon 1/2})$ and $(T_f^{\epsilon 1/2}, f_0^{(\epsilon)})$. Then in the first interval $\log N^{(j)}(q, f)$ approaches $\log 2$. This is no longer true in the second interval, but due to the fast vanishing of the factor in big brackets the corresponding integral drops out for $\epsilon \to 0$. This implies

$$A^{(j,1)}_\epsilon = 2 \log 2 \int_{f_0}^{\infty} df \left( \sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2} - 1} \right) \log N^{(j)}(q, f) + o(1).$$

(91)

Denoting the second line of the last equation\textsuperscript{10} by $J$ and using the same splitting of the integration interval, we get after the substitution $x = qf/\epsilon$ with (15) and (20)

$$J = J_{\text{lower}} + J_{\text{upper}} = \frac{2}{\epsilon q} \int_{qT^{\epsilon 1/2}}^{qT^{\epsilon 1/2} - q^2} \log N(q, x/q) dx.$$

(92)

Then in $J_{\text{lower}}$ the integration variable $x$ is small, allowing an expansion of $\log N(q, x/q)$ in terms of $x$. This yields

$$J_{\text{lower}} = \frac{2T}{\epsilon^{1/2}} \log 2 - 2f_0 \log 2 - \frac{4}{\epsilon q} \int_{qf_0}^{qT^{\epsilon 1/2}} x \cos \left( e \left( \frac{x}{\epsilon q} \right) \pm \gamma \right) dx + o(1).$$

(93)

In $J_{\text{upper}}$ the argument of $\varphi(f)$, i.e. $f = x/(\epsilon q)$, tends to infinity where $\varphi = 0$. This approach to zero is fast enough to justify

$$J_{\text{upper}} = \frac{2}{\epsilon q} \int_{qT^{\epsilon 1/2}}^{qT^{\epsilon 1/2} - q^2} dx \log \left( 1 - 2x \cos \gamma + \sqrt{1 - 4x \cos \gamma - 4x^2 \sin^2 \gamma} \right) + o(1).$$

(94)

Writing this as an integral over $(0, qT)$ minus integrals over $(0, qT^{\epsilon 1/2})$ and over $(qT - q^2, qT)$ we get

\textsuperscript{10} For notational convenience we drop here the index $j$. 

\[ J_{\text{upper}} = \frac{2}{\epsilon q} \int_0^{q \frac{T}{1/2}} \log \left( 1 - 2x \cos \gamma + \sqrt{1 - 4x \cos \gamma - 4x^2 \sin^2 \gamma} \right) \]
\[ - 2q \log \left( 1 - 2qT \cos \gamma + \sqrt{1 - 4qT \cos \gamma - 4q^2T^2 \sin^2 \gamma} \right) \]
\[ - \frac{2T}{\epsilon^{1/2}} \log 2 + \frac{4}{\epsilon q} \int_0^{q \frac{T}{1/2}} x \cos \gamma \, dx + o(1) . \]  

(95)

In the sum $J_{\text{lower}} + J_{\text{upper}}$ the terms $\propto 1/e^{1/2}$ cancel. A further cancellation (up to vanishing terms) takes place for the last terms in (93) and (95). Then, using the integral
\[ \int_0^{1 - \cos \gamma} 2 \sin^2 \gamma \, \log \left( 1 - 2x \cos \gamma + \sqrt{1 - 4x \cos \gamma - 4x^2 \sin^2 \gamma} \right) \]
\[ = \frac{\gamma}{2 \sin \gamma} - \frac{1 + \log(1 + \cos \gamma)}{4 \cos^2 \frac{\gamma}{2}} , \]  

and inserting (93), (95) and (92) into (91) we get\(^1\) with $T_j$ given by (15)
\[ A^{(j,1)} = \frac{2}{\epsilon q} \left( \frac{\gamma_j}{2 \sin \gamma_j} - \frac{1 + \log(1 + \cos \gamma_j)}{4 \cos^2 \gamma_j} \right) \]
\[ + 2 \log 2 \left( \int_{f_0}^{\infty} df \left( \sqrt{f^4 + f^2 - E^2} - 1 \right) - f_0 \right) \]
\[ - 2q \log \left( \frac{1 - \cos \gamma_j}{\sin^2 \gamma_j} \right) + o(1) . \]  

(97)

**Appendix D**

In this appendix we give arguments for the ansatz for the coordinates (41), (42) based on the experience with the explicit example in section 2. If we would take $s(\varphi) = 0$, the variable $\varphi$ would have the meaning of an angle in the $(s_1, s_2)$-plane. Instead we want to argue, that in a well adapted coordinate system $\psi = \rho s(\varphi) + \varphi$ has this meaning. From the mapping pattern of section 2 we have\(^2\)
\[ \frac{y_1 - 1/q}{y_2} = \cot(\pi - \gamma_1 - \psi) = -\cot(\gamma_1 + \psi) . \]  

(98)

On the other side the explicit mapping formulas (9) yield
\[ \frac{y_1 - 1/q}{y_2} = -\cot(\gamma_1 + \varphi) - \frac{\rho \left( 1 + 1/f^2 \right)}{q \sin(\gamma_1 + \varphi)} . \]  

(99)

\(^1\) Reintroducing the index $j$.

\(^2\) We keep the convention to denote the coordinates of the image by $y$'s.
Using (82) a comparison of these two expressions gives

\[
\psi = -\left(3 \frac{1}{E}\right)^{2/3} \frac{\rho}{q} \left(\varphi^{2/3} + \mathcal{O}(\varphi)\right) \pm \varphi + \mathcal{O}(\rho, \varphi^{4/3}).
\]  

(100)

Note that \(\rho\) as used in section 2 is proportional to the radius variable in the sense of section 3 up to higher order corrections, which are not essential in this discussion, whose only purpose is to see the emergence of the structure \(\varphi + \text{factor} \times \rho \varphi^{2/3} \).

To get an impression of the effect of working with \(s(\varphi)\) as described in section 3 for a generic example, i.e. not related to section 2, we have added figure D1.

**Appendix E**

Here we want to comment on some properties of the differential equation for \(F_2(\varphi)\), see (44). As mentioned in the main text, for \(F_1\) in (45)–(47) we can take \(F\) from appendix B. Furthermore, with (77), (83) we get

\[
F'(\varphi) = \pm \frac{\sqrt{(1 + F^2)(1 + F^2 - E^2F^4)}}{EF^2},
\]
\[
F''(\varphi) = \frac{2 + 2F^2 + E^2F^6}{E^2F^5}.
\]

(101)

The plus sign for \(F'\) applies to \(\varphi \in (0, \theta/2)\) and the minus to \(\varphi \in (\theta/2, \theta)\). The relation between \(\varphi\) and \(F\) is one to one in both half-intervals. The constant \(E\) is related to the maximum of \(F\) (i.e. \(F_0 = F(\theta/2) = 1/f_0\)) via

\[
E = \frac{\sqrt{1 + F_0^2}}{F_0}.
\]

(102)
Due to \( F(\theta - \varphi) = F(\varphi) \) we have \( G(\theta - \varphi) = G(\varphi) \) and \( G_1(\theta - \varphi) = -G(\varphi) \). Thus the homogeneous equation related to (44) has both a symmetric as well as an antisymmetric solution. The equation is regular inside the whole interval \( \varphi \in (0, \theta) \), but is singular at its boundary points.

Via
\[
\tilde{F}_2(F) := F_2(\varphi)
\]  
we can replace (44) by a differential equation with respect to \( F \)
\[
\tilde{F}''_2(F) + g(F)\tilde{F}'_2(F) + g_1(F)\tilde{F}_2(F) + m(F) = 0,
\]  
with \(^{13}\)
\[
g(F) = \frac{2 + 10F^2 + 6F^4 - (2 + 10E^2)F^6}{(F + F^3)(E^2F^4 - 1 - F^2)},
\]
\[
g_1(F) = \frac{2 - F^4(2 - E^2(F^2 - 4))}{(F + F^3)(1 + F^2 - E^2F^4)},
\]
\[
m(F) = \frac{M(\varphi(F))}{(dF/d\varphi)^2}.
\]  

Remarkably, the coefficient functions of the homogeneous equation are now explicit known rational functions of \( F \). Besides other benefits, this considerably simplifies the evaluation of numerical solutions.

The equation (104) is regular inside \( F \in (0, F_0) \) and has regular singularities at the boundaries. The one at \( F_0 \) is an artefact of the change of variables from \( \varphi \) to \( F \). The corresponding Frobenius series for the homogeneous equation are power series in \( \sqrt{F_0 - F} \) or in \( (F_0 - F) \), related to odd or even power series in \((\varphi - \theta/2)\) for \( F_2(\varphi) \). Near \( F = 0 \) we have \( g(F) = -2F^2 \times (1 + \mathcal{O}(F^2)) \) and \( g_1(F) = 2F \times (1 + \mathcal{O}(F^2)) \). Therefore, the indicial equation for solving the homogeneous equation by the Frobenius method is \( \alpha(\alpha - 1) + 2\alpha - 2 = 0 \). Its solutions are \( \alpha = -2 \) and \( \alpha = 1 \), corresponding to \( \tilde{F}_2(F) = F^{-2}(1 + \ldots) \) and \( \tilde{F}_2(F) = F(1 + \ldots) \), where in both cases the dots stand for power series in \( F^2 \).

What does this imply for the original differential equation w.r.t. \( \varphi \), i.e. (44)? The just discussed behaviour at \( F \to 0 \) fixes via (82), (83) the behaviour of the solutions of the homogeneous version of (44), both at \( \varphi \to 0 \) and \( \varphi \to \theta \). On both boundary points of the \( \varphi \)-interval we have a vanishing and a diverging solution. From the previous discussion of the behaviour around the midpoint \( \theta/2 \) we also know, that there are symmetric as well as antisymmetric solutions. However, a symmetric or antisymmetric solution, vanishing both at \( \varphi = 0 \) and \( \varphi = \theta \), could only exist, if the spectrum of eigenvalues of the differential operator in (44) would contain the value zero. Certainly, if at all, this could happen only at special values of the parameter \( F_0 \), which contains the information on \( \theta \).

The upshot of this discussion so far is, that for a generic value of \( \theta \) the homogeneous equation related to (44) has two independent solutions \( y_1(\varphi) \) and \( y_2(\varphi) \) with

\(^{13}\) Note, that \( g \) and \( g_1 \) have the same form both for \( \varphi \in (0, \theta/2) \) and \( \varphi \in (\theta/2, \theta) \) since \( F' \) enters quadratically in the calculation of \( g \) and \( g_1 \) from \( G \) and \( G_1 \). Of course this symmetry between the two half-intervals for \( \varphi \) is broken by \( m(F) \) in the generic case.
Let us now proceed to the construction of a solution for the full inhomogeneous equation (44) by the method of varying the constants, i.e. starting with the ansatz

\[ F_2(\varphi) = v_1(\varphi) y_1(\varphi) + v_2(\varphi) y_2(\varphi). \]  

(107)

Then the coefficient functions \( v_j(\varphi) \) have to obey the equations

\[ v'_1(\varphi) = \frac{M(\varphi)}{W(\varphi)} y_2(\varphi), \quad v'_2(\varphi) = -\frac{M(\varphi)}{W(\varphi)} y_1(\varphi). \]  

(108)

Their solutions are

\[ v_1(\varphi) = v_1(0) + \int_0^\varphi \frac{M}{W} y_2 d\varphi, \quad v_2(\varphi) = v_2(0) - \int_0^\varphi \frac{M}{W} y_2 d\varphi. \]  

(109)

Here \( W(\varphi) \) denotes the Wronskian. It is given by

\[ W(\varphi) = \exp \left( -\int_0^\varphi G_1 d\varphi \right) = \text{const} \cdot \left( 1 + \frac{F^2}{F^4} \right)^3. \]  

(110)

From (110), (82) and (50) with (54) and its analog for \( \varphi \to \theta \) we see that the quotient \( \frac{M}{W} \) at both boundary points of the \( \varphi \)-interval tends to nonzero constants. Therefore we get from (109) and (106) near \( \varphi = 0 \) and \( \varphi = \theta \)

\[ F_2(\varphi) = v_1(0) \left( \varphi^{-\frac{2}{3}} + \ldots \right) + v_2(0) \left( \varphi^{\frac{1}{3}} + \ldots \right) + (b_1 + b_2) \left( \varphi^{\frac{2}{3}} + \ldots \right). \]

\[ F_2(\varphi) = v_1(\theta) \left( (\theta - \varphi)^{\frac{1}{3}} + \ldots \right) + v_2(\theta) \left( (\theta - \varphi)^{-\frac{2}{3}} + \ldots \right) \]

\[ + \left( \hat{b}_1 + \hat{b}_2 \right) \left( (\theta - \varphi)^{\frac{2}{3}} + \ldots \right). \]  

(111)

The \( b_j \) and \( \hat{b}_j \) are some constants.

Now vanishing \( F_2 \) at both ends of the \( \varphi \)-interval requires

\[ v_1(0) = v_2(\theta) = 0. \]  

(112)

Using (109) this can be translated in conditions exclusively formulated at one and the same endpoint, e.g. at \( \varphi = 0 \)

\[ v_1(0) = 0 \quad v_2(0) = \int_0^\varphi \frac{M}{W} y_1 d\varphi. \]  

(113)

Note that \( v_1(0) \) and \( v_2(0) \) are just the constants \( B_1 \) and \( B_2 \) in formula (53) of the main text.

**Appendix F**

Here we discuss the asymptotic evaluation of \( A_{\omega,1}^{\omega,0}(\mu_0) \) needed in formula (62) of the main text. One of our aim is the identification of \( \Gamma_{\text{cup}}(\theta) \), defined in equation (86) of appendix B. Therefore, we replace the integration variable \( \varphi \) by \( f = 1/F \) as used in that appendix\(^{14} \)

\(^{14}\) Again \( F_1 \) of the main text can be identified with \( F \) in appendix B.
\begin{equation}
L_1(\varphi) \, d\varphi = \sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2}} \, df.
\end{equation}

Then

\begin{equation}
A_{c,1}^{\rho_0}(\rho_0) = \int_{\rho<\rho_o} \frac{1}{\rho} \sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2}} \, d\rho \, df
= \int_{f_0}^{f_{\text{max}}(\epsilon)} \left( \sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2}} - 1 \right) \, df \int_{\rho_0}^{\rho_f} \frac{d\rho}{\rho}
+ \int_{f_0}^{f_{\text{max}}(\epsilon)} df \int_{\rho_0}^{\rho_f} \frac{d\rho}{\rho},
\end{equation}

with

\begin{equation}
\rho_\epsilon(f) = \frac{\sqrt{a^2 + 4 \epsilon \alpha B f_z} - a}{2B_2}, \quad f_{\text{max}}(\epsilon) = \frac{\rho_0 + \frac{B_2}{a} \rho_0^2 + O(\rho_0^3)}{\epsilon}.
\end{equation}

Use has been made of the asymptotics of \(F_2\) for small \(\varphi\), i.e. large \(f\), see (53), (82) and (48).

Let us call the second and third line of (115) \(I_1\) and \(I_2\) respectively. Then

\begin{equation}
I_1 = \int_{f_0}^{f_{\text{max}}(\epsilon)} df \left( \sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2}} - 1 \right) \log \frac{2\rho_0 B_2}{\sqrt{a^2 + 4\alpha B f_z} - a}.
\end{equation}

For \(f\) fixed one has \(\rho_\epsilon(f) \sim \epsilon f + O(\epsilon^2)\). However, since the upper integration boundary is \(\propto 1/\epsilon\), one has to use this simplification with caution. In the case of \(I_1\) the factor multiplying the logarithm fastly goes to zero \(\propto 1/f^4\), ensuring the finiteness of the integral and allowing the use of the simplified expression for \(\rho_\epsilon(f)\). This yields

\begin{equation}
I_1 = \int_{f_0}^{\infty} df \left( \sqrt{\frac{f^4 + f^2}{f^4 + f^2 - E^2}} - 1 \right) \log \frac{\rho_0}{\epsilon} + O(1).
\end{equation}

\(I_2\) diverges for \(\epsilon \to 0\). Here the use of the same simplification for \(\rho_\epsilon(f)\) is not justified. But due to its simpler total integrand it can be performed explicitly

\begin{equation}
I_2 = (f_{\text{max}}(\epsilon) - f_0) \log \frac{2\rho_0 B_2}{a} - \int_{f_0}^{f_{\text{max}}(\epsilon)} df \log \left( \frac{1 + 4\epsilon B f_z}{a^2} - 1 \right)
= \frac{1}{\epsilon} \left( \rho_0 + \frac{B_2}{2a} \rho_0^2 + O(\rho_0^3) \right) + f_0 \log \epsilon + O(1).
\end{equation}

The sum \(I_1 + I_2\) is then (with use of (86))

\begin{equation}
A_{c,1}^{\rho_0}(\rho_0) = \frac{1}{\epsilon} \left( \rho_0 + \frac{B_2}{2a} \rho_0^2 + O(\rho_0^3) \right) + \frac{1}{2} \Gamma_{\text{cusp}}(\theta) \log \epsilon + O(1).
\end{equation}
